# Roots of torsion polynomials and dominations 

Michel Boileau<br>Steve Boyer<br>Shicheng Wang

#### Abstract

We show that the nonzero roots of the torsion polynomials associated to the infinite cyclic covers of a given compact, connected, orientable 3-manifold $M$ are contained in a compact part of $\mathbb{C}^{*}$ a priori determined by $M$. This result is applied to prove that when $M$ is closed, it dominates at most finitely many $S o l$ manifolds.

## 1 Introduction

All manifolds are connected and orientable in this paper. All homology groups will have $\mathbb{Q}$-coefficients unless otherwise specified.

Suppose that $M$ and $N$ are compact 3-manifolds. We say that $M$ dominates $N$ if there is a nonzero degree map $f:(M, \partial M) \rightarrow(N, \partial N)$.

To each epimorphism $\psi: \pi_{1}(M) \rightarrow \mathbb{Z}$ of the fundamental group of a compact 3manifold one can associate a torsion polynomial $\Delta_{\psi}^{M}(t)$. Our first result shows that the absolute values of the nonzero roots of such polynomials are pinched between two constants depending only on $M$, even though $\pi_{1}(M)$ has infinitely many epimorphisms to $\mathbb{Z}$ when its first Betti number is greater than one. We combine this result with a classical argument due to Wall for nonzero degree maps to show that the same conclusion holds for any 3-manifold dominated by $M$. As an application we prove that a closed 3-manifold $M$ dominates at most finitely many Sol manifolds.

## 2 Roots of torsion polynomials

Given a compact 3-manifold and an epimorphism $\psi: \pi_{1}(M) \rightarrow \mathbb{Z}$, let $\widetilde{M}_{\psi} \rightarrow M$ be the associated infinite cyclic cover. The action on $H_{1}\left(\widetilde{M}_{\psi}\right)$ of $t=\left(T_{\psi}\right)_{*}$ induced by the generator $T_{\psi}$ of the deck transformation group corresponding to $1 \in \mathbb{Z}$ makes $H_{1}\left(\widetilde{M}_{\psi}\right)$ a finitely generated $\Gamma$-module, where $\Gamma=\mathbb{Q}\left[\pi_{1}(M) / \operatorname{ker}(\psi)\right] \cong \mathbb{Q}\left[t, t^{-1}\right]$. Since $\Gamma$ is a principal domain, $H_{1}\left(\widetilde{M}_{\psi}\right) \cong \Gamma^{k} \oplus_{i=1}^{n} \Gamma /\left(p_{i}(t)\right)$ where $0 \neq p_{i}(t) \in \Gamma$. The product $\Delta_{\psi}^{M}(t)=p_{1}(t) p_{2}(t) \ldots p_{n}(t)$, called the torsion polynomial of $\psi$, represents the order of the $\Gamma$-torsion submodule $\operatorname{Tor}\left(H_{1}\left(\widetilde{M}_{\psi}\right)\right)$ of $H_{1}\left(\widetilde{M}_{\psi}\right)$ and is well-defined up to multiplication by some unit $r t^{i}$ of $\Gamma(i \in \mathbb{Z}, 0 \neq r \in \mathbb{Q})$. In particular, the set of nonzero roots $\left\{t_{0} \in \mathbb{C}^{*}: \Delta_{\psi}^{M}\left(t_{0}\right)=0\right\}$ is independent of the choice of $\Delta_{\psi}^{M}(t)$. A straightforward calculation shows that $\Delta_{\psi}^{M}(t)$ coincides, up to units, with the characteristic polynomial of the automorphism of the $\mathbb{Q}$-vector space $\oplus_{i=1}^{n} \Gamma /\left(p_{i}(t)\right)$ corresponding to multiplication by $t$.

Theorem 2.1 A compact, connected, orientable 3-manifold $M$ determines a constant $c_{M}>0$ with the following property: If $t_{0} \in \mathbb{C}^{*}$ is a root of a torsion polynomial $\Delta_{\psi}^{M}(t)$ associated to an epimorphism $\psi: \pi_{1}(M) \rightarrow \mathbb{Z}$, then $1 / c_{M} \leq\left|t_{0}\right| \leq c_{M}$.

Proof Since $1 / t_{0}$ is a root of $\Delta_{-\psi}^{M}(t)$, it suffices to prove the existence of a constant $c_{M}$ such that $\left|t_{0}\right| \leq c_{M}$.

For a group $G$ and $\alpha=\sum_{g \in G} r_{g} g \in \mathbb{Q}[G]$, we set $\|\alpha\|=\sum_{g \in G}\left|r_{g}\right|$.
Consider a finite presentation $\left\langle x_{j}: r_{i}\right\rangle$ of $\pi_{1}(M)$ and let $J=\left(\frac{\partial r_{i}}{\partial x_{j}}\right)$ be the associated Jacobian matrix. Define $k\left(\left\langle x_{j}: r_{i}\right\rangle\right)=\sum_{i, j}\left\|\frac{\partial r_{i}}{\partial x_{j}}\right\| \in \mathbb{N}$ and set

$$
k_{M}=\min \left\{k\left(\left\langle x_{j}: r_{i}\right\rangle\right):\left\langle x_{j}: r_{i}\right\rangle \text { presents } \pi_{1}(M)\right\} .
$$

We assume that $\left\langle x_{j}: r_{i}\right\rangle$ has been chosen to realize $k_{M}$ and that the number $m$ of generators is minimal among such presentations.

Fix an epimorphism $\psi: \pi_{1}(M) \rightarrow \mathbb{Z}$ and let $\Psi$ be the composition $\mathbb{Z}\left[\pi_{1}(M)\right] \rightarrow$ $\mathbb{Q}\left[\pi_{1}(M) / \operatorname{ker}(\psi)\right]=\mathbb{Q}\left[t, t^{-1}\right]$. Recall that $J^{\Psi}=\left(\Psi\left(\frac{\partial r_{i}}{\partial x_{j}}\right)\right)$ presents the $\Gamma$-module $H_{1}\left(\widetilde{M}_{\psi}\right) \oplus \Gamma$ (see Burde and Zieschang [1, Section 9], for example). Set $q_{i j}(t)=$ $\Psi\left(\frac{\partial r_{i}}{\partial x_{j}}\right) \in \mathbb{Q}\left[t, t^{-1}\right]$ and observe that $\left\|q_{i j}(t)\right\| \leq\left\|\frac{\partial r_{i}}{\partial x_{j}}\right\|$. Thus the following claim holds.

Claim 2.2 $\quad \sum_{i, j}\left\|q_{i j}(t)\right\| \leq k_{M}$.

If $r$ denotes the $\Gamma$-rank of $J^{\Psi}$, then $\Delta_{\psi}^{M}(t)$ is, up to units, the g.c.d. of the $r$-rowed minors of $J^{\Psi}$ (see Jacobson [2, Theorem 3.9], for example). Thus it suffices to show that the absolute values of the roots of some nonzero $r$-rowed minor of $J^{\Psi}$ are bounded above by a constant depending only on $M$. To that end, fix such a minor $D(t) \in \mathbb{Z}\left[t, t^{-1}\right]$ which, without loss of generality, we can assume is polynomial in $t$, and let $D_{0}(t)$ be the monic polynomial with the same roots. Since $r \leq m$, the expansion of $D(t)$ in terms of the $q_{i j}(t)$ shows that $m!k_{M}^{m}$ is an upper bound for the sum of the absolute values of its coefficients (cf Claim 2.2). It is evident that the same inequality holds for $D_{0}(t)=t^{s}+b_{s-1} t^{s-1}+\ldots+b_{0}$. If $|t|>R=1+\sum_{i}\left|b_{i}\right|$, then $\left|D_{0}(t)\right|>R^{n}-\left(\sum_{i}\left|b_{i}\right| R^{i}\right) \geq R^{n-1}\left(R-\sum_{i}\left|b_{i}\right|\right)>0$ so that the roots of $D_{0}(t)$ lie in the ball of radius $1+\sum_{i}\left|b_{i}\right|$ centred at zero. Thus the theorem holds with $c_{M}=1+m!k_{M}^{m}$.

We generalize this result with our applications in mind.

Theorem 2.3 For a compact, connected, orientable 3-manifold $M$, there is a constant $c_{M}>0$ with the following property: If $N$ is a compact 3 -manifold dominated by $M$ and $t_{0} \in \mathbb{C}^{*}$ is a root of a torsion polynomial $\Delta_{\psi}^{N}(t)$ of an epimorphism $\psi: \pi_{1}(N) \rightarrow \mathbb{Z}$, then $1 / c_{M} \leq\left|t_{0}\right| \leq c_{M}$

Proof Suppose that $f: M \rightarrow N$ is a nonzero degree map and fix an epimorphism $\psi: \pi_{1}(N) \rightarrow \mathbb{Z}$. Since $\operatorname{deg}(f) \neq 0$, there is an integer $n \geq 1$ such that the image $\left(\psi \circ f_{\#}\right)\left(\pi_{1}(M)\right)=n \mathbb{Z}$. Denote by $\theta: \pi_{1}(M) \rightarrow \mathbb{Z}$ the epimorphism $(1 / n)\left(\psi \circ f_{\#}\right)$ and by $\Delta_{\theta}^{M}(t)$ the associated torsion polynomial. The theorem is a simple consequence of Theorem 2.1 and the following claim.

Claim 2.4 If $t_{0} \in \mathbb{C}^{*}$ is a root of $\Delta_{\psi}^{N}(t)$, then $t_{0}^{n}$ is a root of $\Delta_{\theta}^{M}(t)$.
Proof Let $\mathbb{Q}\left[t, t^{-1}\right]_{f}$ be the $\mathbb{Z}\left[\pi_{1}(M)\right]$-module whose underlying group is $\mathbb{Q}\left[t, t^{-1}\right]$ and whose $\pi_{1}(M)$ action is that determined by the homomorphism $f_{\#}: \pi_{1}(M) \rightarrow$ $\pi_{1}(N)$. Thus for $x \in \pi_{1}(M)$ and $p(t) \in \mathbb{Q}\left[t, t^{-1}\right]$ we have $x \cdot p(t)=t^{\left(\psi \circ f_{\#}\right)(x)} p(t)$. When $n=1$, this action coincides with that of $\mathbb{Z}\left[\pi_{1}(M)\right]$ on $\mathbb{Q}\left[\pi_{1}(M) / \operatorname{ker}\left(\psi \circ f_{\#}\right)\right]$ and so $H_{1}\left(M ; \mathbb{Q}\left[t, t^{-1}\right]_{f}\right) \cong H_{1}\left(\widetilde{M}_{\theta}\right)$, where the latter has the $\Gamma$-action described above. In particular, since $\operatorname{deg}(f) \neq 0$, there is a $\Gamma$-module splitting

$$
\left.H_{1}\left(\widetilde{M}_{\theta}\right)=H_{1}\left(M ; \mathbb{Q}\left[t, t^{-1}\right] f\right)\right) \cong H_{1}\left(N ; \mathbb{Q}\left[t, t^{-1}\right]\right) \oplus K=H_{1}\left(\tilde{N}_{\psi}\right) \oplus K
$$

for some finitely generated $\Gamma$-submodule $K$ of $H_{1}\left(\widetilde{M}_{\theta}\right)$ (see the proof of [7, Lemma 2.1]). Hence when $n=1, \operatorname{Tor}\left(H_{1}\left(\tilde{N}_{\psi}\right)\right)$ is a $\Gamma$-submodule of $\operatorname{Tor}\left(H_{1}\left(\widetilde{M}_{\theta}\right)\right)$, and so its order $\Delta_{\psi}^{N}(t)$ divides $\Delta_{\theta}^{M}(t)$, which implies the claim in this case.

Next suppose $n>1$ and let $\tilde{N}_{(\psi, n)} \rightarrow N$ be the $n$-fold cyclic cover with $\pi_{1}\left(\tilde{N}_{(\psi, n)}\right)$ the kernel of the $(\bmod n)$ reduction of $\psi$. Then $f$ lifts to a $\pi_{1}$-surjective, nonzero degree map $\tilde{f}: M \rightarrow \tilde{N}_{(\psi, n)}=N^{\prime}$. Let

$$
\psi^{\prime}: \pi_{1}\left(N^{\prime}\right) \rightarrow n \mathbb{Z} \xrightarrow{1 / n} \mathbb{Z}
$$

be the epimorphism induced by $\psi$. The case $n=1$ shows that any nonzero root of $\Delta_{\psi^{\prime}}^{N^{\prime}}(t)$ is also a root of $\Delta_{\theta}^{M}(t)$. On the other hand, it is easy to see that $\left(T_{\psi^{\prime}}\right)_{*}=\left(T_{\psi}\right)_{*}^{n}$ on $H_{1}\left(\widetilde{N}^{\prime} \psi^{\prime}\right)=H_{1}\left(\tilde{N}_{\psi}\right)$ so that if $t_{0} \in \mathbb{C}^{*}$ is a root of $\Delta_{\psi}^{N}(t)$, then $t_{0}^{n} \in \mathbb{C}^{*}$ is a root of $\Delta_{\psi^{\prime}}^{N^{\prime}}(t)$, and therefore of $\Delta_{\theta}^{M}(t)$. This completes the proof of the claim and therefore of Theorem 2.3.

## $3 \mathbb{Q}$-Homology surface bundles

Let $F$ be a compact surface and $A$ an abelian group. An $A$-homology $F \times I$ is a 3-manifold $W$ with boundary containing two disjoint surfaces $F_{1} \cong F_{2} \cong F$ such that
(i) $\overline{\partial W \backslash\left(F_{1} \cup F_{2}\right)} \cong \partial F \times I$ where $\partial F \times\{0\}=\partial F_{1}, \partial F \times\{1\}=\partial F_{2}$, and
(ii) the inclusion induced homomorphism $H_{*}\left(F_{1} ; A\right) \rightarrow H_{*}(W ; A)$ is an isomorphism.
(Duality and universal coefficients shows that (ii) is equivalent to each of the following three conditions: $H_{*}\left(W, F_{1} ; A\right)=0 ; H_{*}\left(W, F_{2} ; A\right)=0 ; H_{*}\left(F_{2} ; A\right) \stackrel{\cong}{\Longrightarrow} H_{*}(W ; A)$.) Note that $W$ determines orientations on $F_{1}$ and $F_{2}$ well-defined up to simultaneous reversal. Thus the set $\operatorname{Homeo}\left(F_{2}, F_{1}\right)^{-}$of orientation reversing homeomorphisms $F_{2} \rightarrow F_{1}$ is well-defined. For each $\varphi \in \operatorname{Homeo}\left(F_{2}, F_{1}\right)^{-}$we define $W_{\varphi}$ to be the compact, orientable manifold obtained from $W$ by identifying $F_{2}$ to $F_{1}$ via $\varphi$. The composition

$$
H_{1}\left(F_{1} ; A\right) \xrightarrow{\cong} H_{1}(W ; A) \xrightarrow{\cong} H_{1}\left(F_{2} ; A\right) \xrightarrow{\varphi_{*}} H_{1}\left(F_{1} ; A\right)
$$

determines an isomorphism

$$
\varphi_{*}^{W}: H_{1}\left(F_{1} ; A\right) \rightarrow H_{1}\left(F_{1} ; A\right)
$$

which we call the algebraic monodromy of $W_{\varphi}$. Set

$$
\Delta_{\varphi}^{W}(t)=\operatorname{det}\left(\varphi_{*}^{W}-t I\right)
$$

We call $W_{\varphi}$ an $A$-homology $F$ bundle.

Theorem 3.1 For a compact, connected, orientable 3-manifold $M$, there is a constant $c_{M}>0$ with the following property: If $W_{\varphi}$ is a $\mathbb{Q}$-homology surface bundle which is dominated by $M$, then the absolute values of the roots of the characteristic polynomial $\Delta_{\varphi}^{W}(t)$ of $\varphi_{*}^{W}$ are pinched between $1 / c_{M}$ and $c_{M}$.

Proof Let $F \subset W_{\varphi}$ be the nonseparating surface corresponding to $F_{1}=\varphi\left(F_{2}\right)$. It determines a nonzero class $[F] \in H_{2}\left(W_{\varphi}\right)$, well-defined up to sign, and an epimorphism

$$
\psi: \pi_{1}\left(W_{\varphi} ; \mathbb{Z}\right) \rightarrow \mathbb{Z}, \alpha \mapsto \alpha \cdot[F]
$$

Let $\widetilde{W}_{\varphi} \rightarrow W_{\varphi}$ be the infinite cyclic cover associated to this epimorphism $\psi$. Note that $H_{1}\left(\widetilde{W}_{\varphi}\right)=H_{1}\left(W_{\varphi} ; \Gamma\right)$ where $\Gamma$ is the $\mathbb{Z}\left[\pi_{1}\left(W_{\varphi}\right)\right]-\operatorname{module} \mathbb{Q}\left[\pi_{1}\left(W_{\varphi}\right) / \operatorname{ker}(\psi)\right] \cong$ $\mathbb{Q}[\mathbb{Z}] \cong \mathbb{Q}\left[t, t^{-1}\right]$. The $\mathbb{Z}\left[\pi_{1}\left(W_{\varphi}\right)\right]$ action on $H_{1}\left(\widetilde{W}_{\varphi}\right)$ factors through one of $\Gamma$ in such a way that $t=\left(T_{\varphi}\right)_{*}$ where $T_{\varphi}: \widetilde{W}_{\varphi} \rightarrow \widetilde{W}_{\varphi}$ is a generator of the group of deck transformations of $\widetilde{W}_{\varphi} \rightarrow W_{\varphi}$.

Claim 3.2 $H_{1}\left(\widetilde{W}_{\varphi}\right)$ is a torsion module over $\Gamma$ whose order is represented by $\Delta_{\varphi}^{W}(t)$.
Proof The quotient map $W \rightarrow W_{\varphi}$ lifts to an inclusion of $W$ into $\widetilde{W}_{\varphi}$ with image $\widetilde{W}_{0}$ say. Let $\widetilde{F}_{0} \subset \partial \widetilde{W}_{0}$ correspond to $F_{1}$ and set $\widetilde{W}_{j}=T_{\varphi}^{j}\left(\widetilde{W}_{0}\right), \widetilde{F}_{j}=T_{\varphi}^{j}\left(\widetilde{F}_{\tilde{W}}\right)$. Then $\widetilde{W}_{\varphi}=\cup_{j} \widetilde{W}_{j}$ where $\widetilde{W}_{j} \cap \widetilde{W}_{k}=\varnothing$ if $|j-k|>1$ and $\widetilde{W}_{j} \cap \widetilde{W}_{j-1}=\widetilde{F}_{j}$. Since $W$ is a $\mathbb{Q}$-homology $F_{1} \times I$, the composition $H_{1}\left(F_{1}\right)=H_{1}\left(\widetilde{F}_{0}\right) \rightarrow H_{1}\left(\widetilde{W}_{\varphi}\right)$ is an isomorphism under which the algebraic monodromy $\varphi_{*}^{W}: H_{1}\left(F_{1}\right) \rightarrow H_{1}\left(F_{1}\right)$ corresponds to $\left(T_{\varphi}\right)_{*}: H_{1}\left(\widetilde{W}_{\varphi}\right) \rightarrow H_{1}\left(\widetilde{W}_{\varphi}\right)$.
It is now clear that $H_{1}\left(\widetilde{W}_{\varphi}\right)$ is a torsion module over $\Gamma$ since $H_{1}\left(\widetilde{W}_{\varphi}\right) \cong H_{1}\left(F_{1}\right)$ is finite dimensional over $\mathbb{Q}$. Hence the order of $H_{1}\left(\widetilde{W}_{\varphi}\right)$ as a $\Gamma$-module corresponds to the characteristic polynomial of the automorphism $\left(T_{\varphi}\right)_{*}$ of the $\mathbb{Q}$-vector space $H_{1}\left(\widetilde{W}_{\varphi}\right)$, at least up to multiplication by some unit $\Gamma$. Since $\left(T_{\varphi}\right)_{*}$ corresponds to $\varphi_{*}^{W}$ under $H_{1}\left(F_{1}\right) \xrightarrow{\cong} H_{1}\left(\widetilde{W}_{\varphi}\right), \Delta_{\varphi}^{W}(t)$ also represents the order of $H_{1}\left(\widetilde{W}_{\varphi}\right)$.

Claim 3.2 shows that, up to multiplication by a unit, $\Delta_{\varphi}^{W}(t)$ is the torsion polynomial of the epimorphism $\psi$. Theorem 3.1 now follows from Theorem 2.3.

Corollary 3.3 Let $W$ be a $\mathbb{Q}$-homology $F \times I$. A compact, connected, orientable 3-manifold $M$ determines a finite subset $\mathcal{P}_{(M, W)}$ of $\mathbb{Q}[t]$ such that if $M$ dominates $W_{\varphi}$, then the characteristic polynomial of $\varphi_{*}^{W}$ is contained in $\mathcal{P}_{(M, W)}$.

Proof Let $\beta_{1}(F)$ be the first Betti number of $F$. The reader will verify that since $W$ is a $\mathbb{Q}$-homology $F \times I$, we can choose bases of for $H_{1}\left(F_{1} ; \mathbb{Z}\right)$ and $H_{1}\left(F_{2} ; \mathbb{Z}\right)$ with respect to which the matrix $X$ of $H_{1}\left(F_{1}\right) \rightarrow H_{1}(W) \rightarrow H_{1}\left(F_{2}\right)$ lies in $S L_{\beta_{1}(F)}(\mathbb{Q})$
and the matrix $Y$ of $H_{1}\left(F_{2}\right) \xrightarrow{\varphi_{*}} H_{1}\left(F_{1}\right)$ lies in $S L_{\beta_{1}(F)}(\mathbb{Z})$. Now $\varphi_{*}^{W}$ is represented by $Y X$ so the denominators of its entries are bounded above by some constant $N$. Thus the coefficients of $\Delta_{\varphi}^{W}(t)=\operatorname{det}(Y X-t I)$ have denominators bounded above by $N^{\beta_{1}(F)}$ and since its degree is $\beta_{1}(F)$, the corollary follows from Theorem 3.1.

Remark 3.4 (1) The finite set $\mathcal{P}_{(M, W)}$ described in the corollary depends on both $M$ and $W$. In the case when $W \cong F \times I$, the matrix $X$ of the proof of Corollary 3.3 lies in $S L_{\beta_{1}(F)}(\mathbb{Z})$, so it is easy to see that $\mathcal{P}_{(M, W)}$ depends only on $M$ and the Euler characteristic of the fibre.
(2) A given compact 3-manifold $M$ can be the total space of infinitely many distinct surface bundles over the circle. Moreover, there are cases where the Euler characteristic of the fibres are unbounded. However, Theorem 3.1 provides the following constraint on the monodromy of any such bundle structure on $M$.

Corollary 3.5 Given a compact 3-manifold $M$, there is a constant $c_{M}>0$ such that the absolute values of the roots of the characteristic polynomial of the algebraic monodromy of any surface bundle structure on $M$ are pinched between $1 / c_{M}$ and $c_{M}$. $\square$

Recall that an element $\varphi \in S L_{2}(\mathbb{Z})$ is called hyperbolic if $|\operatorname{trace}(\varphi)|>2$.
Corollary 3.6 A closed, connected, orientable 3-manifold $M$ dominates only finitely many Sol manifolds.

Proof First suppose that $M$ dominates a torus bundle over the circle with hyperbolic monodromy $\varphi \in S L_{2}(\mathbb{Z})$. Corollary 3.3 shows that there are only finitely many possibilities for $\operatorname{trace}(\varphi)$, which is the negative of the coefficient of $t$ in $\Delta_{\varphi}^{T^{2} \times I}(t)$. On the other hand, there are only finitely many $S L_{2}(\mathbb{Z})$ conjugacy classes of hyperbolic elements of $S L_{2}(\mathbb{Z})$ with a given trace (eg see Wang and Zhou [9, Lemma 8]). Since the homeomorphism type of a torus bundle over the circle depends only on the conjugacy class of its monodromy $\varphi \in S L_{2}(\mathbb{Z})$, it follows that a closed, connected, orientable 3-manifold can dominate at most finitely many torus bundles over the circle with hyperbolic monodromy. But a closed, connected Sol manifold $N$ is double covered by such a bundle $\widetilde{N}$ and so if $M$ dominates $N$, some double cover of $\widetilde{M}$ dominates $\widetilde{N}$. Since $M$ has only finitely many double covers, there are only finitely many possibilities for $\tilde{N}$, and therefore for $N[4 ; 3]$.

It is known that if a closed, orientable 3-manifold dominates a manifold which admits a geometric structure based on the geometries $\mathbb{S}^{3}, N i l$, or $\widetilde{S L_{2}}$, then it dominates infinitely many distinct such manifolds [8]. This is false for the remaining geometries.

Corollary 3.7 A closed, orientable 3-manifold dominates at most finitely many manifolds admitting an $\mathbb{S}^{2} \times \mathbb{R}, \mathbb{E}^{3}, \mathbb{H}^{3}, \mathbb{H}^{2} \times \mathbb{R}$, or Sol structure.

Proof The corollary holds for dominations of $\mathbb{S}^{2} \times \mathbb{R}$ and $\mathbb{E}^{3}$ manifolds since there are only finitely many such spaces (see eg Scott [5]). It holds for dominations of hyperbolic manifolds by Soma [6], for $\mathbb{H}^{2} \times \mathbb{R}$ manifolds by Wang and Zhou [9], and for Sol manifolds by Corollary 3.6.
