INTRINSIC EXTENSIONS OF RINGS

CARL FAITH AND YUZO UTUMI

A module M is an essential extension of a submodule N in case $K \cap N \neq 0$ for each nonzero submodule K of M. If S is a subring of a ring R, and if ${}_{S}R$, ${}_{S}S$ denote the left S-modules naturally defined by the ring operations of R, then R is a left quotient ring of S in case ${}_{S}R$ is an essential extension of ${}_{S}S$.

We shall discuss the following problem: (1) Characterize the condition that a ring extension R of S is a left quotient ring of S wholly in terms of the relative left ideal structures of R and S.

A ring extension R of S is left intrinsic over S in case $K \cap S \neq 0$ for each nonzero left ideal K of R. Evidently each left quotient ring R of S is left intrinsic over S but an obvious example (when R is a field and S a subfield $\neq R$) shows that the converse fails. Nevertheless, we ask: (2) When is the condition R is left intrinsic over S a solution to (1)?

We now specialize S by requiring that:

- (i) S possesses a left quotient ring which is a (von Neumann) regular ring, or equivalently (R. E. Johnson [2]) by requiring that the left singular ideal of S vanishes. For such a ring there exists a maximal left quotient ring \hat{S} which is unique up to isomorphism over S, and which is itself a regular ring ([2]). To eliminate the field example we require that:
- (ii) \hat{S} possesses no strongly regular ideals $\neq 0$. Under these hypotheses we present the following solution to (1).
- A. THEOREM (2.6). Let S satisfy (i) and (ii). Then an extension ring R of S is a left quotient ring of S if and only if R is a left intrinsic extension of S such that for each closed left ideal A of S there corresponds a left ideal B of R such that $B \cap S = A$.

(See § 1 for definitions.)

Regarding (2) we add a rather dubious final hypothesis:

- (iii) \hat{S} is right intrinsic over S.
- B. THEOREM (3.1). If S satisfies (i)-(iii), then an extension ring R of S is a left quotient ring of S if and only if R is left

intrinsic over S. (Then there exists a ring monomorphism of R into \hat{S} which is the identity on S.)

Combining B with a theorem of Goldie [1] we obtain:

- C. THEOREM (3.2). Let S be a prime ring which is both left and right noetherian, and assume that S is not an integral domain. Let Q denote the classical quotient ring of S ([1]). Then an extension ring R of S is left intrinsic over S if and only if there exists a ring monomorphism of R into Q which is the identity on S.
- 1. A ring S is strongly regular (resp. regular) if for any $x \in S$ there exists $y \in S$ such that $x^2y = x$ (resp. xyx = x); an ideal I of S is strongly regular if I is a strongly regular ring.

Let S be a ring. Then ${}_sM$ will denote that M is a left S-module, and ${}_sS$ denotes the left S-module defined naturally by the ring operations in S. ${}_sM$ is an essential extension of a submodule N in case $K \cap N \neq 0$ for each submodule $K \neq 0$ of M. Then, N is said to be an essential submodule of M. An essential left ideal of S is a left ideal of S which is an essential submodule of ${}_sS$. (Thus a left ideal I of S is essential if and only if S is a left intrinsic extension of I.)

An element $x \in {}_{S}M$ is singular in case the annihilator of x in S is an essential left ideal of S. It is known that the set $Z({}_{S}M)$ of singular elements of ${}_{S}M$ is a submodule of ${}_{S}M$, called the singular submodule of ${}_{S}M$; $Z({}_{S}S)$ is an ideal of S called the left singular ideal of S.

If Z(sS)=0, then S is said to be a J_l -ring, and \hat{S} denotes its maximal left quotient ring; \hat{S} is a regular ring with identity, and is left self-injective. If R is any left self-injective ring with identity, then it is known (Utumi [4], Lemma 8) that Z(R) coincides with the Jacobson radical J(R) of R, and that the difference R-J(R) is a regular ring.

A left ideal A of a ring S is *closed* if there is no left ideal of S which is a proper essential extension of A.

In case S is a J_l -ring it is known that the set of closed left ideals of S forms a complete complemented modular lattice L(S). If R is a left quotient ring of S, R is also a J_l -ring, and L(R) is isomorphic to L(S) by the correspondence $A(\in L(R)) \to A \cap S$. Thus, in this case, the following condition is satisfied:

(1.1) Condition. Let R be an extension ring of a ring S. For any closed left ideal A of S there is a left ideal B of R such that $B \cap S = A$.

We call an extension ring R of S left strongly intrinsic if R is a left intrinsic extension of S, and if Condition 1.1 is fulfilled.

- (1.2) Lemma. Let R be a left intrinsic extension of a J_i -ring S. Suppose that the maximal left quotient ring of S is right intrinsic over S. Then R is a left strongly intrinsic extension of S.
- *Proof.* Let A be a closed left ideal of S. By [5, Theorem 2.2] A is an annihilator left ideal of S. Hence $B \cap S = A$ for some annihilator left ideal B of R, as desired.

It is evident that Condition 1.1 is equivalent to the following:

(1.3) If A and B are left ideals of S such that $A \cap B = 0$, then there exists a left ideal C of R such that $C \supset A$ and $C \cap B = 0$.

Let R be a left strongly intrinsic extension of a ring S. Then the following three properties are easily seen:

- (1.4) If $A \cap B = 0$ for a left ideal A of R and a left ideal B of S, there is a left ideal C of R such that $A \cap C = 0$.
- (1.5) If the sum of left ideals $\{A_i\}$ of S is direct, so is the sum of $\{A_i + RA_i\}$.
- (1.6) If A is an essential left ideal of S, then A + RA is an essential left ideal of R. If C is an essential left ideal of R, $C \cap S$ is also an essential left ideal of S.
- (1.7) LEMMA. Let R be a left strongly intrinsic extension of a ring S. Then the following properties are equivalent:
 - (i) S is a J_i -ring;
 - (ii) R is a J_l -ring;
- (iii) the singular submodule Z(sR) of the left S-module R is zero.

Proof. By (1.6) it is obvious that $Z(_{S}R) \subset Z(_{R}R) \subset Z(_{S}R)$. Hence $Z(_{S}R) = Z(_{R}R)$. This shows the equivalence of (ii) and (iii). Now $Z(_{S}S) = Z(_{S}R) \cap S = Z(_{R}R) \cap S$. Since $Z(_{R}R)$ is an ideal of R, $Z(_{R}R) = 0$ if and only if $Z(_{R}R) \cap S = 0$. Therefore (i) is equivalent to (ii), as desired.

The following proposition is known:

(1.8) Let S be a J_l -ring. A left ideal A of S is closed if and only if $Bx \subset A$ for $x \in S$ and an essential left ideal B of S implies that $x \in A$.

(1.9) LEMMA. Let R be a left strongly intrinsic extension of a J_{ι} -ring S. Then the lattice L(R) of closed left ideals of R is isomorphic to the lattice L(S) of closed left ideals of S under contraction $A \to A \cap S$.

Proof. It is direct from (1.6) and (1.8) that $A \cap S$ is closed for any closed A. Suppose that $A_1 \cap S = A_2 \cap S$ for $A_1, A_2 \in L(R)$. It is known that any intersection of closed left ideals of a J_i -ring is closed. Thus, $(A_3 =)$ $A_1 \cap A_2 \in L(R)$. Let B be a left ideal of R such that $B \subset A_1$, $B \cap A_3 = 0$. It follows then that $B \cap S = 0$. Hence B = 0, which shows that $A_1 = A_3$, since A_3 is closed. Similarly $A_2 = A_3$, and therefore $A_1 = A_2$. Finally we shall show that the correspondence is onto. Let $C \in L(S)$. By (1.1), $C = D \cap S$ for some left ideal D of R. By Zorn's lemma there exists a maximal left ideal E of R such that $E \cap S = C$. Let F be a left ideal of R which contains E properly. Then $F \cap S \neq C$. Since C is closed, we can find a nonzero left ideal G of S such that $G \subset F \cap S$ and $G \cap C = 0$. By (1.1) there is a left ideal H of R such that $H \cap S$ is an essential extension of G. Then $0 = (H \cap S) \cap C = ((H \cap F) \cap E) \cap S$. Since R is left intrinsic over S, we have that $(H \cap F) \cap E = 0$. This implies that F is not an essential extension of E. Therefore $E \in L(R)$, completing the proof.

2. The following proposition is easily verified:

(2.1) Let M be a left S-module with zero singular submodule. Suppose that a left ideal A of S is an essential extension of a left ideal B of S. Let v and w be left S-homomorphisms of A into M. If (v-w)B=0, then v=w.

In fact, v-w induces a homomorphism of A/B into M. By assumption Z(A/B)=A/B. Hence $(v-w)A=Z((v-w)A)\subset Z(M)=0$, as desired.

A left S-module M is called injective if for any left ideal A of S, and for any left S-homomorphism v of A into M there exists an element x such that v(a) = ax for every $a \in A$. A ring S is called left self injective if the left S-module S is injective, and S has a unit element. Any left self injective ring which is semisimple (in the sense of Jacobson) is regular (in the sense of von Neumann). As is known, the maximal left quotient ring of a J_i -ring is semisimple, in the sense of Jacobson, and left self injective.

We denote by l(P, Q) the set of $x \in P$ with xQ = 0. Similarly r(P, Q) denotes the right annihilator, in P, of Q.

(2.2) LEMMA. Let R be a semisimple left self injective ring, and suppose that it is a left strongly intrinsic extension of a ring-

S. Then the left S-module R is an injective module with zero singular submodule.

Proof. Since R is regular, it is a J_i -ring. By Lemma (1.7), $Z(_{S}R)=0$. Let A be a left ideal of S, and v a left S-homomorphism of A into R. Denote the left ideal of S generated by an element x by $(x)_i$. By Zorn's lemma there is a maximal subset $\{x_i\}$ of A such that the sum B of $(x_i)_i$ is direct. Evidently A is an essential extension of B. By (1.5), the sum of $\{Sx_i\}$ is also direct. Now $l(S,x_i) \subset l(S,v(x_i))$, that is, $l(R,x_i) \cap S \subset l(R,v(x)) \cap S$. Since any annihilator left ideal of the J_i -ring R is closed, it follows by Lemma 1.9 that $l(R,x_i) \subset l(R,v(x_i))$. This shows that $x_i \to v(x_i)$ generates a left R-homomorphism w of $\sum_i Rx_i$ into R. By the injectivity of $_RR$ there exists an element $a \in R$ such that $v(x_i) = x_i a$ for every i. Thus the homomorphism v and the right multiplication of a coincide on a. Since a is essential over a, it follows by (2.1) that a is given by the right multiplication of a, completing the proof.

(2.3) THEOREM. Let R be an extension ring of a ring S, and suppose that the left S-module R is an injective module with zero singular submodule. Then S is a J₁-ring. Let T be the maximal one among such submodules of the left S-module R that are essential over the left S-module S. Then T forms a subring of R, and in fact it is the maximal left quotient ring of S.

Proof. Since $Z({}_{S}S) = Z({}_{S}R) \cap S = 0$, S is a J_{l} -ring. Let E be the endomorphism ring of ${}_{S}R$, and let $v \in E$. In case ${}_{S}R$ is essential over Ker v, $Z({}_{S}R/{\rm Ker}\,v) = R/{\rm Ker}\,v$, and so $Im\,v = Z(Im\,v) \subset Z(R) = 0$, whence v = 0. In view of [4, Lemma 8] it follows from this that E is semisimple, and T is uniquely determined. Since ${}_{S}T$ is essential over ${}_{S}S$, it is easy to see that the set D(x) of elements y of S such that $yx \in S$ is an essential left ideal of S for each $x \in T$. Now we denote by U the set of $x \in R$ such that D(x) is an essential left ideal of S. Clearly $T \subset U$. It is not difficult to show that U is a subring of R. Since $Z({}_{S}R) = 0$, ${}_{S}U$ is essential over ${}_{S}S$. Hence $U \subset T$, therefore T = U. Thus, T forms a subring of R. T is the maximal left quotient ring of S because ${}_{S}T$ is the maximal essential extension of ${}_{S}S$.

(2.4) LEMMA. Let R be a ring with unit, and suppose that it is a left strongly intrinsic extension of a semisimple left self injective ring S. Then every idempotent of R belongs to S.

Proof. Let $e = e^2 \in R$. Then $Re \in L(R)$, the lattice of closed left ideals of R. Hence $Re \cap S \in L(S)$, the lattice of closed left ideals of

S, by Lemma 1.9. Since every closed left ideal of S is a principal left ideal generated by an idempotent, $S \cap Re = Sf$ for some $f = f^2 \in S$. Evidently $Rf \cap S = Sf = Re \cap S$, and hence Re = Rf by Lemma 1.9. Similarly we can find an idempotent $g \in S$ such that R(1-e) = Rg. Since S is regular, Sf + Sg = Sh for some $h = h^2 \in S$. Then Rh = R, and h = 1. Hence 1 = xf + yg for some $x, y \in S$. Also,

$$e - xf = e - (1 - yg) = yg - (1 - e) \in Rg + R(1 - e) = R(1 - e)$$
.

Hence $e - xf \in Re \cap R(1 - e) = 0$, and therefore $e = xf \in S$, completing the proof.

By virtue of [5, Corollary to Theorem 4], any semisimple left self injective ring R is decomposed into the direct sum of two ideals R_1 and R_2 in such a way that R_1 is strongly regular, and R_2 does not contain any nonzero strongly regular ideals. The decomposition is unique. By [5, Theorem 2], R_2 is generated by idempotents.

- (2.5) THEOREM. Let R be semisimple left self injective ring, and let $R = R_1 \oplus R_2$ be the decomposition into ideals mentioned above. Suppose that R is a left strongly intrinsic extension of a ring S. Then there is a subring T of R_1 with the following properties:
 - (i) T contains every idempotent of R_1 ,
 - (ii) T is a strongly regular, (left) self injective ring and
 - (iii) $T \oplus R_2$ is the maximal left quotient ring of S.

Proof. By Lemma 2.2, $_sR$ is injective and $Z(_sR)=0$. Thus, by Lemma 2.3, R contains as a subring the maximal left quotient ring Q of S. Since R is left intrinsic over S, and $R \supset Q \supset S$, it is evident that R is left intrinsic over S. Let S be a closed left ideal of S. Then S is left strongly intrinsic over S and hence S is left strongly intrinsic over S. Thus, by Lemma 2.4 every idempotent of S belongs to S is generated by idempotents, S is generated by idempotents, S is its ideal S. Thus, the strong regularity of S follows from the fact that a regular ring is strongly regular if and only if it has no nonzero nilpotent elements, completing the proof.

- (2.6) THEOREM. Let S be a J_l -ring. Suppose that the maximal left quotient ring of S does not contain any nonzero strongly regular ideals. Then any left strongly intrinsic extension of S is a left quotient ring of S.
- *Proof.* Let R be a left strongly intrinsic extension of S, and denote by Q the maximal left quotient ring of R. By Lemma 1.9,

Q is a left strongly intrinsic extension of S. Let $Q=Q_1 \oplus Q_2$ where Q_1 is a strongly regular ideal of Q, and Q_2 is an ideal of Q which does not contain any nonzero strongly regular ideals. By Theorem 2.5 there is a strongly regular subring T of Q_1 such that $T \oplus Q_2$ is the maximal left quotient ring of S. T contains every idempotent of Q_1 , especially the unit element of Q_1 . Since T=0 by assumption, it follows that $Q_1=0$. Thus, $Q=Q_2$ is the maximal left quotient ring of S. Since $Q \supset R \supset S$, R is a left quotient ring of S, as desired.

- 3. The following is the main theorem.
- (3.1) THEOREM. Let S be a J_l -ring. Suppose that the maximal left quotient ring of S is right intrinsic, and does not contain any nonzero strongly regular ideals. Then any left intrinsic extension of S is a left quotient ring.

Proof. By Lemma 1.2 any left intrinsic extension of S is left strongly intrinsic over S, and hence it is a left quotient ring of S by Theorem 2.6, as desired.

Goldie proved in [1; Theorem 13] that if a prime ring S satisfies the maximum conditions for left and right ideals, then S may be imbedded into a simple ring R with minimum condition in such a way that R is the classical quotient ring of S in the following sense:

- (i) Every non-zero-divisor of S has the inverse in R;
- (ii) every element x of R is of the forms $a^{-1}b$ and cd^{-1} for some a, b, c and $d \in S$. In this case S is a J_i -ring, and R is the maximal left quotient ring of S. Since R is a right quotient ring of S, it is right intrinsic over S. R contains a nonzero strongly regular ideal if and only if R is a division ring, that is, S is an Ore domain. Thus, by Theorem 3.1 we obtain the following.
- 3.2. Theorem. Let S be a prime ring with maximum conditions for left and right ideals, and suppose that it is not an Ore domain. Then an extension ring of S is left (or right) intrinsic over S if and only if it is isomorphic, over S, to a between ring of S and the classical quotient ring of S.

Mathematical papers intended for publication in the *Pacific Journal of Mathematics* should by typewritten (double spaced), and on submission, must be accompanied by a separate author's résumé. Manuscripts may be sent to any one of the four editors. All other communications to the editors should be addressed to the managing editor, L. J. Paige at the University of California, Los Angeles 24, California.

50 reprints per author of each article are furnished free of charge; additional copies may be obtained at cost in multiples of 50.

The *Pacific Journal of Mathematics* is published quarterly, in March, June, September, and December. Effective with Volume 13 the price per volume (4 numbers) is \$18.00; single issues, \$5.00. Special price for current issues to individual faculty members of supporting institutions and to individual members of the American Mathematical Society: \$8.00 per volume; single issues \$2.50. Back numbers are available.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley 8, California.
