HOMOTOPY GROUPS OF PL-EMBEDDING SPACES

L. S. HUSCH

Let N be a compact PL-n-manifold, and let M be a PLm-manifold without boundary. Two of the major problems in PL-topology are to determine conditions such that (1) any continuous map of N into M can be homotoped to a PLembedding, and (2) two homotopic PL-embeddings are PLisotopic.

If C(N, M) is the space of continuous maps of N into Mwith the compact open topology, and if PL(N, M) is the subspace of PL-embeddings, one can consider the map $i_{\sharp}: \Pi_0(PL(N, M)) \to \Pi_0(C(N, M))$ induced by inclusion. If (1) is true, then i_{\sharp} is onto; if (2) is true, then i_{\sharp} is one-to-one. In this paper, we investigate the higher homotopy groups of PL(N, M) and C(N, M).

Irwin has shown that if N is a closed manifold, $m \ge n+3$, then sufficient conditions for (1) are that N is (2n - m)—connected and M is (2n - m + 1)—connected. By raising the connectivities of N and M by one, Zeeman [7] proved (2).

By using Proposition 1 of Morlet [4] and Irwin [3], one can easily show the following theorem by using techniques similar to the proof of Theorem 2 below.

THEOREM 1. Let N be a closed (2n + s + 1 - m)—connected PLn-manifold and let M be a (2n + s + 2 - m)—connected PL-mmanifold without boundary, $m \ge n + 3$. The homomorphism i_{\sharp} : $\Pi_s (PL(N, M)) \rightarrow \Pi_s(C(N, M))$ induced by inclusion is an isomorphism; if the connectivities of N and M are lowered by one, then i_{\sharp} is onto.

An analogous theorem in the differential case has been proved by J. P. Dax [1], [2].

If N has a nonempty boundary, then Dancis, Hudson and Tindell (independently and unpublished) have shown that if N has a k-dimensional spine with $m \ge \{n + 3, n + k\}$, this is a sufficient condition for (1). If $m \ge \{n + 3, n + k + 1\}$, they obtain (2). We generalize.

THEOREM 2. Let N be a compact PL-n-manifold with k-spine K, k < n, and let M be a PL-m-manifold without boundary. If $m \ge n + k + s + 1$, the homomorphism i_{\sharp} : $\prod_{s}(PL(N, M)) \rightarrow \prod_{s}(C(N, M))$ induced by inclusion is an isomorphism; if $m \ge n + k + s$, i_{\sharp} is onto.

Note that the codimension 3 restriction is eliminated. In §3,

we obtain some consequences of this theorem and its proof.

The author wishes to express his gratitude to N. Max who read a preliminary version of this paper and suggested some corrections.

In this paper, we shall consider PL(N, M) and C(C, M) as Δ -sets (-i.e., as semisimplicial complexes in which the degeneracy maps are ignored). In §1, we list the basic definitions and results on Δ -sets which we shall use. One may use either Rourke and Sanderson [6] or Morlet [5]. [Morlet uses the terminology "quasisimplicial" set.]

We shall assume familiarity with either [1] or [7] and shall use terminology therein with one exception. When referring to piecewise linear maps or manifolds, we shall always use the prefix "PL-".

Let X and Y be polyhedra. In this paper p_1 and p_2 will always denote projections of $X \times Y$ onto the first and second factors respectively. An isotopy between X and Y will be represented as a family of embeddings $f_t: X \to Y, t \in I = [0, 1]$.

1. Δ -sets. Let Δ^n denote the standard *n*-simplex with ordered vertices v_0, v_1, \dots, v_n . The *i*-th face map $\partial_i: \Delta^{n-1} \to \Delta^n$ is the order preserving simplicial embedding which omits v_i . Δ is the category whose objects are Δ^n , $n = 0, 1, \dots$ and whose morphisms are generated by the face maps. A Δ -set (Δ -group) is a contravariant functor from Δ to the category of sets (groups). A Δ -map between Δ -sets (Δ -groups) is a natural transformation between the functors.

If X is a Δ -set, $X^k = X(\Delta^k)$ is the set of *k*-simplexes and the maps $\partial_i = X(\partial_i)$ are called *face maps*. We shall be interested in pointed Δ -sets in which we distinguish a simplex $*^k \in X^k$ for each k and designate $* \subset X$ as the sub- Δ -set of X consisting of these simplexes and maps ∂_i defined by $\partial_i *^k = *^{k-1}$.

With each ordered simplicial complex K, we associate a Δ -set, also designated by K, whose k-simplexes are order-preserving simplicial embeddings of Δ^k into K.

Let $\Lambda_{n,i} = \operatorname{Cl} (\operatorname{bdry} \varDelta^n - \partial_i \varDelta^{n-1})$. A \varDelta -set X is called a Kan \varDelta -set if every \varDelta -map $f: \Lambda_{n,i} \to X$ can be extended to a \varDelta -map $f_1: \varDelta^n \to X$.

If X is a Kan Δ -set and P is a polyhedron, a map $f: P \to X$ is a Δ -map $f: K \to X$ where K is an ordered triangulation of P. $f_0, f_1: P \to X$ are homotopic if there is a map $F: P \times I \to X$ such that $F | P \times \{i\} = f_i, i = 0, 1.$ [P;X] denotes the set of homotopy classes. We shall need the following two propositions which are proved by Rourke and Sanderson.

PROPOSITION 1. Any homotopy class in [P; X] is represented by a Δ -map $f: K \rightarrow X$ where K is any ordered triangulation of P.

PROPOSITION 2. Let Q be a subpolyhedron of P and let

 $h: Q \times I \cup P \times \{0\} \rightarrow X$ be a Δ -map to a Kan Δ -set X; then h extends to a Δ -map $h': P \times I \rightarrow X$.

If X is a pointed Kan Δ -set, then the *n*-th homotopy group of $X, \Pi_n X = [I^n, \text{bdry } I^n; X, *]$, the homotopy classes of Δ -maps of pairs, where I^n is the *PL*-*n*-cell.

C(N, M)(PL(N, M)) is made into a Δ -set by defining the ksimplexes to be maps (*PL*-embeddings) $f: N \times \Delta^k \to M \times \Delta^k$ such that $p_2 f = p_2$ and defining $\partial_i f = f | N \times \partial_i \Delta^k$.

PROPOSITION 3. C(N, M) and PL(N, M) are Kan Δ -sets.

Proof. Let $f: \Lambda_{n,i} \to PL(N, M)$ be a Δ -map. f can then be considered as a *PL*-embedding

 $f: N imes arLambda_{n,i} \longrightarrow M imes arLambda_{n,i}$

such that $p_2 f = p_2$. Using the fact that the pair $(\Lambda_{n,i} \times I, \Lambda_{n,i} \times \{0\})$ is *PL*-homeomorphic to $(\mathcal{A}^n, \mathcal{A}_{n,i})$, one can easily construct the desired extension.

2. Proof of Theorem 1. The following two propositions are generalizations to product spaces of the simplicial approximation and general position theorems. They can be proved similarly.

PROPOSITION 4. Let M and Y be PL-manifolds and let $P \subseteq Q$ be compact polyhedra. Suppose $f: Q \to M \times Y$ is a continuous map such that f | P is PL. There exists a homotopy $h_i: M \times Y \to M \times Y$, $t \in I$, such that

- (i) $p_2h_t = p_2$ for $t \in I$;
- (ii) $h_t f | P = f \text{ for } t \in I;$
- (iii) $h_1 f: Q \to M \times Y$ is PL.

PROPOSITION 5. Let M and Y be PL-manifolds and let $P \subseteq Q$ be compact polyhedra. Suppose $f: Q \to M \times Y$ is a PL-map such that f | P is a PL-embedding. There exists a PL-homotopy $h_t: M \times Y \to M \times Y$, $t \in I$, such that

- (i) $p_2h_t = p_2$ for $t \in I$;
- (ii) $h_t f | P = f \text{ for } t \in I;$
- (iii) the singular set of $h_1 f$ has dimension $\leq 2 \dim Q \dim (M \times Y)$;
- (iv) the branch set of $h_1 f$ has dimension $< 2 \dim Q \dim (M \times Y)$.

The following two constructions are needed frequently in the following propositions.

PROPOSITION 6. Let N be a PL-n-manifold with k-spine K. Let

P be a polyhedron in N such that $\dim P + \dim K + 1 \leq \dim N$. There exists a PL-isotopy H_t of N, $t \in I$, such that $H_0 = identity$ and $H_1(N) \cap P = \emptyset$.

Proof. By general position, we can find a *PL*-ambient isotopy L_i of N so that $L_1K \cap P = \emptyset$. Let N' be a regular neighborhood of L_1K in N such that $N' \cap P = \emptyset$. Note that L_1K is also a spine of N. Hence, by the uniqueness theorem of regular neighborhoods, there is a *PL*-isotopy H_i of $N, t \in I$, such that H_0 = identity and $H_1(N) = N'$.

CONSTRUCTION α . Let I_+^s be a *PL*-cell in the interior of I^s and let U be a neighborhood of $\operatorname{Cl}(I^s - I_+^s)$ in I^s . Let U_0, U_1 be regular neighborhoods of $\operatorname{Cl}(I^s - I_+^s)$ in I^s such that $U_0 \subseteq \operatorname{int} U_1$ and $U_1 \subseteq U$. Let $\varphi \colon S^{s-1} \times I \longrightarrow \operatorname{Cl}(U_1 - U_0)$ be a *PL*-homeomorphism such that $\varphi(S^{s-1} \times \{i\}) = \operatorname{bdry} U_i \cap \operatorname{int} I^s, \ i = 0, 1.$

PROPOSITION 7. Let N, K, M be as in Theorem 2 with $m \ge n + k + s$. Let $f: N \times I^s \to M \times I^s$ be a PL-map such that $p_2 f = p_2$ and such that there exists a neighborhood U of $\operatorname{Cl}(I^s - I^s_+)$ such that $f \mid N \times U$ is a PL-embedding, then there exists a PL-homotopy $f_t: N \times I^s \to M \times I^s$ and a neighborhood V of $\operatorname{Cl}(I^s - I^s_+)$ in I^s such that

- (i) $f_0 = f, p_2 f_t = p_2, t \in I;$
- (ii) $f_t \mid V = f, t \in I;$
- (iii) $f_1: N \times I^s \to M \times I^s$ is a PL-embedding.

Proof. By Proposition 5, we can assume that the singular set T of f has dimension $\leq 2(n + s) - (m + s)$, the branch set $B \subset T$ of f has dimension < 2(n + s) - (m + s), and that $f \mid K \times I^s$ is a *PL*-embedding. By Proposition 6, there is a *PL*-isotopy H_t of N such that H_0 = identity and $H_1(N) \cap p_1B = \emptyset$. Hence there is no loss of generality in assuming that $f \mid p_1^{-1}(H_1(N)) \times I^s$ is a *PL*-embedding.

Let U_0 , U_1 and φ be as in construction α . Define $F_i: N \times I^s \rightarrow N \times I^s$, $t \in I$, by

$$(H_t(x), y) \quad y \in \operatorname{Cl} (I^s - U_1) \ F_t(x, y) = (x, y) \quad y \in U_0 \ (H_{tt_0}(x), y) \quad y \in \operatorname{Cl} (U_1 - U_0), \, y = arphi(y_0, t_0).$$
 Let $f_t = fF_t$ and $V = U_0.$

The following is the theorem of Dancis, Hudson and Tindell mentioned in the introduction. We include the proof for completeness.

PROPOSITION 8. Let N, K, M be as in Theorem 2 with $m \ge n + k$. There exists a PL-embedding $f: N \rightarrow M$. *Proof.* Let $f': N \to M$ be a continuous map and approximate f' by a *PL*-map f'' such that f''/K is a *PL*-embedding and f'' is in general position. Let $B \subset S$ be the branch and singular set of f'' respectively. By Proposition 6, there is a *PL*-isotopy H_t , $t \in I$, of N such that $H_1(N) \cap S = S \cap K$. Let $f = f''H_1$.

REMARK. We shall make PL(N, M) and C(N, M) into pointed Δ -sets by defining the basepoint complex * as follows. Let $*^{*}(x, y) = (f(x), y), x \in N, y \in \Delta^{*}$ where f is defined in Proposition 8. The face operators are defined naturally.

The proof of the following proposition is well known.

PROPOSITION 9. Let N, M, K be as in Theorem 2 with $m \ge n + k$. Let $g: N \times I^s \to M \times I^s$ represent an s-simplex in PL(N, M)(C(N, M)) such that

$$g \mid N imes ext{ bdry } I^s = st^s \mid N imes ext{ bdry } I^s$$
 ,

g is homotopic rel bdry I^{s} in PL(N, M)(C(N, M)) to g': $N \times I^{s} \rightarrow M \times I^{s}$ such that for some neighborhood U of $Cl(I^{s} - I^{s} +)$ in I^{s} , g' | $N \times U = *^{s} | N \times U$.

PROPOSITION 10. Let N, M, K be as in Theorem 2 with $m \ge n + k + s + 1$ and let $F_t: N \times I^s \to M \times I^s$ be a PL-homotopy such that

(i) F_i are PL-embeddings, i = 0, 1;

(ii) $p_2F_t = p_2, t \in I$:

(iii) there exists a neighborhood U of $\operatorname{Cl}(I^s - I^s_+)$ in I^s such that $F_t \mid N \times U = *^s$.

Then there exists a PL-isotopy $G_i: N \times I_s \rightarrow M \times I^s$ such that

(i) $G_i = F_i \text{ for } i = 0, 1;$

(ii) $p_2G_t = p_2, t \in I$:

(iii) there exists a neighborhood V of $\operatorname{Cl}(I^s - I^s_+)$ in I^s such that $G_t \mid N \times V = *^s$.

Proof. Note that there is no loss of generality in assuming that there is an $\varepsilon > 0$ so that F_t are *PL*-embeddings, $t \in [0, \varepsilon] \cup [1 - \varepsilon, 1]$. However, now this is a restatement of Proposition 7.

The proof of Theorem 2 now follows easily from the above propositions.

3. Applications. One of the immediate consequences of Theorem 2 is a partial generalization of Hudson's "concordance implies isotopy"

theorem [2]. (See also Proposition 1 of [4].)

COROLLARY 1. Let N be a compact PL-n-manifold with k-spine K, k < n, and let M be a PL-m-manifold without boundary. Let $f: N \times I^s \to M \times I^s$ be a PL-embedding such that $p_2f \mid N \times bdry I^s = p_2$. Then if $m \ge n + k + s$, there exists a PL-embedding $F: N \times I^s \to M \times I^s$ such that $F \mid N \times bdry I^s = f$ and $p_2F = p_2$. If $m \ge n + k + s + 1$, f and F can be chosen to be isotopic rel $N \times bdry I^s$.

Let X be an s-dimensional polyhedron and let $p: E \to X$ and $q: F \to X$ be *PL*-fiber bundles with fibers N and M respectively with structure groups Aut (N) and Aut (M) where

(i) N is a PL-n-manifold with k-spine, k < n;

(ii) M is a PL-m-manifold without boundary;

(iii) Aut (N) and Aut (M) are the groups of *PL*-automorphisms of N and M, respectively.

By triangulating X and by using the propositions above together with induction on the dimension of the simplexes of X, one can easily prove the following.

COROLLARY 2. If $f: E \to F$ is a continuous bundle map (-i.e., qf = p) and $m \ge n + k + s$, then f is homotopic through bundles maps to a PL-bundle map which is an embedding of E into F. If $m \ge n + k + s + 1$; any two PL-bundle embeddings of E into F are isotopic through bundle maps.

A PL_m -bundle is a PL-bundle $q: F \to X$ whose fiber is Euclidean *m*-space \mathbb{R}^m and whose structural group is the *PL*-automorphisms of \mathbb{R}^m mod the origin.

COROLLARY 3. Let N be a PL-n-manifold with k-spine, k < n; let $p: E \to X^s$ be a PL-fiber bundle with N as fiber and Aut(N) as structural group. If $m \ge n + k + s$, then for any PL_m -bundle $q: F \to X$, there exists a PL-bundle map $f: E \to F$ which is an embedding. If $m \ge n + k + s + 1$, then any such two PL-bundle embeddings are isotopic through bundle maps.
