AUTOMORPHISMS OF EXTRA SPECIAL GROUPS AND NONVANISHING DEGREE 2 COHOMOLOGY

ROBERT L. GRIESS, JR.

If E is an extra-special 2-group, it is known that $\operatorname{Aut}(E)/\operatorname{Inn}(E)$ is isomorphic to an orthogonal group. We prove that this extension is nonsplit, except in small cases. As a consequence, the nonvanishing of the second cohomology groups of certain classical groups (defined over F_2) on their standard modules may be inferred. Also, a criterion for a subgroup of these orthogonal groups to have a nonsplit extension over the standard module is given.

1. Introduction. Let E be an extra-special 2-group of order 2^{2n+1} , $n \ge 1$. That is, E' = Z(E) and E/E' is elementary abelian. Any extra-special group may be expressed as a central product of dihedral groups D_8 of order 8 and quaternion groups Q_8 of order 8, with the central subgroup of order 2 in each factor amalgamated. The expression of E as such a central product is not unique in general because $D_8 \circ D_8 \cong Q_8 \circ Q_8$. However, the number of quaternion central factors is unique modulo 2 for any such expression (see [9] or [12]).

The commutator quotient E/E' may be regarded as a vector space over the field of two elements F_2 equipped with a quadratic form q, where $q(xE') = x^2 \in E'$, for $x \in E$ (we identify E' with the additive group of F_2). The bilinear form b associated with q is defined by b(xE', yE') = q(xE')q(yE')q(xyE') (in multiplicative notation, and, in fact $b(xE', yE') = x^{-1}y^{-1}xy = [x, y]$ is the commutator of x and y. Clearly, any automorphism of E induces an automorphism of E/E'which preserves this quadratic form. Hence, as Inn (E) consider with the group of central automorphisms of E, Aut (E)/Inn (E) is isomorphic with a subgroup of some orthogonal group $0^{\pm}(2n, 2)$.

On the other hand, it is not difficult to see that of the full orthogonal group may be lifted to automorphisms of E ([12], 13.9). However, as we shall prove, there is usually no subgroup of Aut (E), (Aut (E)') isomorphic to the relevant (simple) orthogonal group complementing Inn (E). For the case $|E| \ge 2^{\circ}$, the argument is surprisingly easy, and gives a criterion for a subgroups of $0^{\circ}(2n, 2)$ to have a nonsplit extension over the standard 2n-dimensional module.

With similar considerations, one can see that, if E is an extraspecial 2-group of order 2^{2n+1} , $Y \cong \mathbb{Z}_4$, the group $E \circ Y$ (with a group of order two amalgamated) has $\mathbb{Z}_2 \times \text{Sp}(2n, 2)$ as the outer automorphism group (the isomorphism $D_8 \circ \mathbb{Z}_4 \cong Q_8 \circ \mathbb{Z}_4$ is useful here; [12], p. 361).

We argue as follows. Since $Y = Z(E \circ Y)$, Y is characteristic in $E \circ Y$. There is an automorphism α of $E \circ Y$ which inverts Y and centralizes E. Thus, B, the centralizer of Y in Aut $(E \circ Y)$ has index 2 in Aut $(E \circ Y)$. Now Inn $(E \circ Y)$ has order $|E/E'| = 2^{2n}$. Also, Inn $(E \circ Y) \subseteq M$, the group of central automorphisms, and $|M| = |\text{Hom } ((E \circ Y), Y)| = 2^{2n+1}$. It follows that $M = \text{Inn } (E \circ Y) \times \langle \alpha \rangle$. Note, $B \cap M = \text{Inn } (E \circ Y)$.

Since B preserves the alternating form $E \circ Y/Y \times E \circ Y/Y \to E'$ induced by commutation, $B/\text{Inn}(E \circ Y)$ is isomorphic to a subgroup of Sp (2n, 2). To get $B/\text{Inn}(E \circ Y) \cong$ Sp (2n, 2), we must show that every symplectic transformation on $E \circ Y/Y$ can be lifted to $E \circ Y$. But, a variation of the argument of [12] showing Out (E) is isomorphic to the full orthogonal group can easily be made. The relevant fact is that every coset of Y in E contains involutions and elements of order 4.

So, we have $\langle B, \alpha \rangle = \operatorname{Aut}(E \circ Y)$. But clearly $\langle B, \alpha \rangle / \operatorname{Inn}(E \circ Y) \cong \mathbb{Z}_2 \times \operatorname{Sp}(2n, 2)$ because $\langle \alpha \rangle$ covers $M / \operatorname{Inn}(E \circ Y) \triangleleft \operatorname{Out}(E \circ Y)$ and we already know B is normal in $\operatorname{Out}(E \circ Y)$.

By the well-known connection between equivalence classes of group extensions and elements of the relevant second cohomology group [13], our results on automorphism groups may be viewed as statements about nonvanishing cohomology. Some related results are presented as well (Theorems 2, 3, 4, 5). Unfortunately, our methods do not indicate how big these nonzero cohomology groups are.

The corresponding question about extra-special *p*-groups leads to split extensions. More precisely, if E is isomorphic to an extra-special *p*-group of order p^{2n+1} , $n \ge 1$, *p* an odd prime, then

(i) if E has exponent p, $Out(E) \cong Sp(2n, p)H$, where H is cyclic of order p-1 and H effects an outer automorphism of order 2 on Sp(2n, p).

(ii) If E has exponent p^2 , $Out(E) \cong WSD$, where W is a normal extra-special group of order p^{2n-1} , exponent p, $S \cong Out(W)' \cong$ Sp (2n - 2, p), and $D \cong \mathbb{Z}_{p-1}$.

In either case, $\operatorname{Aut}(E)$ is a split extension of $\operatorname{Out}(E)$ by $\operatorname{Inn}(E)$. The splitting in (i) follows from an argument as in [12], p. 124. Case (ii) is technically more complicated. The details are omitted.

The author thanks J. McLaughlin for many helpful conversations and, particularly, for contributing Theorem 3. The author also thanks J. G. Thompson for pointing out that the centralizer of an involution in Conway's group 1, [4] is a nonsplit extension of an extra-special group of order 2^9 by the simple orthogonal group $\Omega^+(8, 2) \cong D_4(2)$, and for raising the general question which led to Theorem 1. 2. Notation and assumed results. Most group-theoretic notation used is fairly standard (see [9] or [12]). In particular, \sum_n , resp. A_n denotes the symmetric, resp. alternating group of degree n; Sp (2n, 2)denotes the symplectic group of dimension 2n defined over the field of 2 elements; $0^+(2n, 2)$, resp. $0^-(2n, 2)$, denotes the orthogonal group of dimension 2n defined over the field of 2 elements stabilizing a quadratic form of index n, resp. n - 1 (i.e., for which there is a maximal isotropic subspace of dimension n, resp. n - 1); $\Omega^+(2n, 2)$, resp. $\Omega^-(2n, 2)$ denotes the subgroup of index 2 in $0^+(2n, 2)$, resp. $0^-(2n, 2)$, for which Dickson invariant is zero ([6], p. 64)-it is the commutator subgroup of the orthogonal group, except for $\Omega^+(4, 2)$, and excluding $\Omega^+(4,2)$, it is generated by products of two orthogonal transvections ([6], p. 36) (here, we are differing slightly from common practice in which $\Omega^{\pm}(2n, 2)$ is defined to be $0^{\pm}(2n, 2)'$).

We assume the reader is familiar with elementary properties of symplectic and orthogonal groups in characteristic 2 [6]. To get subgroup structure, it is often useful to use the isomorphisms of these groups with groups of Lie type [3]:

$$egin{array}{lll} arDelta^+(2n,\,2) &\cong D_n(2) & \Omega^-(2n,\,2) \cong {}^2D_n(2) \ {
m Sp}\,(2n,\,2) &\cong B_n(2) \cong C_n(2) \;, \;\; {
m for} \;\; n \geqq 2 \;. \end{array}$$

We collect some of our most often used results below.

PROPOSITION 0. (i) For $n \ge 2$, $\Omega^{\pm}(2n, 2)$ is simple, except for $\Omega^{+}(4, 2) \cong SL(2, 2) \times SL(2, 2)$.

(ii) For $n \geq 3$, Sp (2n, 2) is simple, and Sp (4, 2) $\cong \sum_{b}$.

(iii) For $n \ge 2$, $\Omega^{\pm}(2n, 2)$ acts transitively on nonsingular vectors and on nonzero singular vectors.

(iv) For $n \ge 3$, the stabilizer in $\Omega^{\pm}(2n, 2)$ of a nonsingular vector is isomorphic to $0(2n - 1, 2) \cong \text{Sp}(2n - 2, 2)$.

(v) For $n \geq 3$, the stabilizer S in $\Omega^{\pm}(2n, 2)$ of a nonzero singular vector is a split extension of $0_2(S)$, elementary abelian of order 2^{2n-2} , by $S/0_2(S) \cong \Omega^{\pm}(2n-2, 2)$.

We present notation used in Theorem 1. We set

$$E_1 \cong D_8$$

 $E_{n+1} = E_n \circ F_n, n = 1, 2, \cdots$ where $F_n \cong D_8$
 $V_n = E_n / \langle e \rangle$ where $\langle e \rangle = E'_n$

and, in the obvious way, we regard

$$E_1 \subset E_2 \subset \cdots \subset E_n$$

 $V_1 \subset V_2 \subset \cdots \subset V_n$.

We call E_n an extra-special group of *positive type*, order 2^{2n+1} . The other isomorphism type, the *negative type*, of extra-special group of order 2^{2n+1} is denoted by T_n . We have

$$egin{array}{ll} T_{_1} \cong Q_8 \ T_{_{n+1}} \cong T_{_1} \circ E_n \cong T_{_n} \circ E_1 \ ext{,} & ext{for} \quad n \geqq 1 \ ext{.} \end{array}$$

We use the bar convention for image under $E_n \rightarrow V_n$ and for other homomorphic image when specified. We use * to denote preimages. All our central products will have amalgamated central subgroup of order 2.

Some general references for cohomology of groups are [1], [11], [12], and [14].

3. Statement of results. We momentarily identify the two groups Out(E) and $0^{e}(2n, 2)$.

$$\operatorname{Out}(E) \cong 0^{\varepsilon}(2n, 2)$$
.

Also, we identify E/E' with Inn (E), thus making Inn (E) the standard module for Out (E). Let G be a subgroup of Out (E). Consider (*), the extension of G by Inn (E) induced by Aut (E):

THEOREM 0. Let W be a subspace of Inn(E), |W| = 4, so that the nontrivial elements of W consists of two singular vectors x, y and one nonsingular vector z. Suppose G has a subgroup K satisfying

(a) K fixes the vector z:

- (b) K contains an involution t with $x^t = y, y^t = x, z^t = z$:
- (c) K has no subgroup of index 2.

Then, (*) is a nonsplit extension.

THEOREM 1. Let E be an extra-special group of order 2^{2n+1} , $n \ge 1$. We identify Out (E) with the relevant orthogonal group $0^{\epsilon}(2n, 2)$, $\varepsilon = \pm$. Consider the exact sequences of groups

(*)
$$1 \longrightarrow \operatorname{Inn}(E) \longrightarrow \operatorname{Aut}(E) \xrightarrow{\pi} 0^{\epsilon}(2n, 2) \longrightarrow 1$$
,
 $1 \longrightarrow \operatorname{Inn}(E) \longrightarrow A(E) \xrightarrow{\pi} \Omega^{\epsilon}(2n, 2) \longrightarrow 1$,

where A(E) is the preimage of $\Omega^{*}(2n, 2)$ in Aut (E) under π . (a) If E is of positive type, the sequences of (*) are nonsplit when $n \geq 3$, split when n = 1, 2.

(b) If E is of negative type, the sequences of (*) are nonsplit when $n \ge 3$, split when n = 1, 2.

COROLLARY 1. The second cohomology groups $H^2(0^{\pm}(2n, 2), V)$ and $H^2(\Omega^{\pm}(2n, 2), V)$ are nonzero for $n \geq 3$, where V is the usual 2n-dimensional space on which $0^{\pm}(2n, 2)$ acts. Also, $H^2(0^{+}(4, 2), V) = 0$ and $H^2(\Omega^{+}(4, 2), V) = 0$.

COROLLARY 2. Let E be an extra-special group of order 2^{2n+1} and let Y be cyclic of order 4. Then $\operatorname{Out} (E \circ Y) \cong \mathbb{Z}_2 \times \operatorname{Sp}(2n, 2)$. The extensions

$$\begin{array}{l} 1 \longrightarrow \operatorname{Inn} (E \circ Y) \longrightarrow \operatorname{Aut} (E \circ Y) \stackrel{\pi}{\longrightarrow} Z_{2} \times \operatorname{Sp} (2n, 2) \longrightarrow 1 , \\ 1 \longrightarrow \operatorname{Inn} (E \circ Y) \longrightarrow A(E \circ Y) \stackrel{\pi}{\longrightarrow} \operatorname{Sp} (2n, 2) \longrightarrow 1 , \end{array}$$

where $A(E \circ Y)$ is the centralizer in Aut $(E \circ Y)$ of Y, are nonsplit for $n \ge 3$. Consequently, the second cohomology group $H^2(\text{Sp}(2n, 2), V)$ is nonzero for $n \ge 3$, where V is the standard 2n-dimensional module for Sp (2n, 2).

THEOREM 2.

 $H^{2}(0^{-}(4, 2), V) = 0$

and

$$H^2(\Omega^-(4, 2), V) = 0$$
,

where V is the usual 4-dimensional module on which $0^{-}(4, 2)$ acts.

THEOREM 3. (J. McLaughlin) $H^2(\text{Sp}(4, 2), V) \neq 0$, where V is the usual 4-dimensional module. More precisely, the cup-product

$$H^{1}(\operatorname{Sp}(4, 2), \mathbb{Z}_{2}) \times H^{1}(\operatorname{Sp}(4, 2), \mathbb{V}) \longrightarrow H^{2}(\operatorname{Sp}(4, 2), \mathbb{V})$$

is not the zero pairing.

THEOREM 4. $H^2(\text{Sp}(4, 2)', V) = 0, V$ the standard module.

THEOREM 5. (a) Let E be an extra-special group of order 2^{2n+1} , $n \ge 1$, type $\varepsilon = \pm$. There is a group H having the properties

$$egin{aligned} 0_2(H)&\cong E,\, Z(H)=Z(0_2(H))\ H/0_2(H)&\cong 0^*(2n,\,2),\ \ H/Z(H)&\cong \mathrm{Aut}\,(E) \end{aligned}$$

and H has a faithful, ordinary, irreducible complex representation of degree 2^{n} .

(b) Let E be as above and let $Y \cong Z_4$. There is a group H_0 having the properties

and H_0 has two faithful, ordinary irreducible complex representations of degree 2^n . These are interchanged by the action of Aut $(E \circ Y)$ on $A(E \circ Y)$ and by complex conjugation.

(c) Let F be a splitting field for E or $E \circ Z_4$ (e.g. F = Q, the rationals, will do for E_n , and $Q(\sqrt{-1})$ will do for T_n or $E \circ Z_4$).

(i) If W = H or H_0 , then the 2ⁿ-dimensional representation, when restricted to W', may be written in F.

(ii) If $W_0 = H$, H'E, H_0 or H'_0E then every faithful irreducible character of χ of W_0 has the form $\chi = \xi \eta$, where E is contained in the kernel of ξ and η is the character of a 2ⁿ-dimensional representation from (a) if $W_0 = H$ or H'E, or from (b) if $W_0 = H_0$ or H'_0E .

COROLLARY 3. The exact sequences of Corollary 2 are nonsplit for n = 2.

Note that Corollary 3 implies the first assertion of Theorem 3.

4. Proof of Theorem 0, and for $n \ge 4$, proof of Theorem 1 (a), (b), and Corollary 1. Assume the hypotheses of Theorem 0. Let W^* be the preimage of W in E. Then $W^* \cong D_8$. Assume (*) is split. Then, there is a complement to Inn(E) in B, which we may as well identify with G. Now, $t \in G$ effects an outer automorphism of order 2 on W^* . The structure of $\text{Aut}(W^*)$ implies that t inverts the maximal cyclic subgroup U of W^* . But K acts on U, and since Khas no subgroup of index 2, K must centralize U. This gives a contradiction, since $t \in K$. Therefore, the complement does not exist, and the Theorem is proven.

We can now get the assertions of Theorem 1 (a), (b) and Corollary 1, for $n \ge 4$. Let G = Out(E) or Out(E)'. Choose any W as in the Theorem and let K be the stabilizer of the nonsingular vector in Out(E)'; we have $K \cong 0(2n - 1, 2) \cong \text{Sp}(2n - 2, 2)$. Since $n \ge 4$, Kis simple. One can easily find an involution t with the required properties. Theorem 0 now implies the assertions of Theorem 1, and Corollary 1 as well.

If n = 3, the arguments are different and will be given in §§5 and 13. Here $K \cong \sum_{6}$, the symmetric group. The trouble is, since |K:K'| = 2, we are not immediately led to a contradiction, for t may not lie in K'. EXAMPLE. It may be easy to check the hypotheses of the Theorem in some cases. Let G be Conway's group 1. Let Λ be the Leech lattice, and set $V = \Lambda/2\Lambda$. The quadratic form on Λ induces an F_2 valued quadratic form on V which is nondegenerate. Also, G preserves the form on V. Consider a triangle in Λ of type 322. We take for W the union of $0 \in V$ and the image in V of the edges of this triangle. Let K^* be the stabilizer in .0 of the subgroup of Λ generated by the edge of type 3; $K^* \cong .3 \times Z(.0)$. Let K be the image of K^* in G. It is not difficult to find an involution t^* of .0 which switches the two edges of type 2 in our triangle. Finally, set t equal to the image of t^* in G. Since K is simple, all parts of the hypothesis of our Theorem are satisfied. It follows that there is a nonsplit extension of G by V (we have embedded in G in Out (E), E extra special of order 2^{25} , and identified V with E/E' to get this). Of course, we also get $H^2(.1, \Lambda/2\Lambda) \neq 0$.

5. Proof of Theorem 1 (b), Corollary 1, the case
$$n = 3$$
.

It suffices to show that

 $1 \longrightarrow \operatorname{Inn} (T_{\mathfrak{s}}) \longrightarrow \operatorname{Aut} (T_{\mathfrak{s}})' \longrightarrow \operatorname{Out} (T_{\mathfrak{s}})' \longrightarrow 1$

is a nonsplit extension. In this case, $\operatorname{Out}(T_3)' \cong \Omega^-(6, 2) \cong U_4(2)$.

We assume the extension splits. The considerations of $\S4$ allow us to assume the following: there is a coset $x\langle e \rangle$ of $\langle e \rangle = T'_{\mathfrak{z}}$ with $x^2 = e$ and $x^d = xe$ for $d \in K - K'$, where $K \cong \sum_6$ is the stabilizer of $x\langle e \rangle$ in the complement. We may write $T_3 = T_1 \circ F$, where $x \in F \cong E_2$. There is an automorphism α of order 3 which centralizes F and acts nontrivially on $T_1 \cong Q_8$. Let Q be the subgroup of K' which is congruent to $\langle \alpha \rangle$ modulo Inn (T_3) . Any subgroup of order 3 in $K \cong \sum_{6}$ is centralized by some $d \in K \setminus K'$. Thus $\langle Q, d \rangle \cong Z_6$ acts on $T_1 = [T_3, \overline{Q}]$. But Aut $(T_1) \cong \sum_{i}$ implies that d centralizes T_1 . So, choose $y \in T_1$, |y| = 4. Then $y^d = y$, whence $(xy)^d = xey = (xy)e$. But xy = yximplies xy is an involution. The stabilizer of the singular vector $xy\langle e \rangle$ in the complement is isomorphic to a perfect group which is an extension of $\Omega^{-}(4, 2) \cong A_5$ by an elementary abelian group of order 2⁴. Since this perfect group must centralize every element of the coset $xy\langle e \rangle$, we have a contradiction to $(xy)^d = xye$. Thus, the complement does not exist in the case n = 3 either.

6. Proof of Theorem 2.

LEMMA. Let V be the usual 4-dimensional F_2 -space on which $\Omega^{-}(4, 2)$ acts.

Then V is a projective and injective $F_2\Omega^-(4, 2)$ -module. Consequently, $H^i(\Omega^-(4, 2), V) = 0$ for all $i \ge 1$.

Proof. We claim that V is absolutely irreducible. Let k be a field of characteristic 2 containing the |G|th roots of unity, where $G = \Omega^-(4, 2)$. It is well-known that kG has four irreducible modules of dimensions 1, 2, 2, and 4. It suffices to show that $k \otimes V$ has no 1-or 2-dimensional constituent. If there were a 1-dimensional constituent, an element of order 5 in G would have 1 as an eigenvalue on $k \otimes V$, hence also on V. This is impossible as |V| = 16. Assume no trivial constituents. But on each of these, an element of order 3 in G has no fixed points, although it stabilizes both singular and nonsingular vectors of V, contradiction.

Thus, V is absolutely irreducible. Since $k \otimes V$ has dimension 4, the full 2-part of the order of $G, k \otimes V$ lies in a block of defect 0 (see [2], especially (6A)), hence is projective and injective for kG. As V is an F_2G -summand of $k \otimes V$, V is projective and injective.

Since cohomology vanishes on injectives in positive degree (see [11] or [14]), the last assertion is immediate. The lemma is proven. Now consider an extension

$$(+)1 \longrightarrow V \longrightarrow E \longrightarrow 0^{-}(4, 2) \longrightarrow 1$$

of $0^{-}(4, 2) \cong \sum_{5}$ by its usual 4-dimensional F_2 -module. By the lemma, (+) restricted to $\Omega^{-}(4, 2)$ is split because $H^2(\Omega^{-}(4, 2), V) = 0$. Furthermore, $H^1(\Omega^{-}(4, 2), V) = 0$ implies that all subgroups of E isomorphic to $\Omega^{-}(4, 2)$ are conjugate.

We can now show $H^{2}(0^{-}(4, 2), V) = 0$ by applying the Frattinilike argument suggested in [12], page 124. Namely, let D denote a subgroup of E isomorphic to $\Omega^{-}(4, 2)$. Since all such D are conjugate, $E = VN_{E}(D)$. Now, $N_{E}(D) \cap V = 1$ because $\Omega^{-}(4, 2)$ fixes no vector in V^{*} . Thus $N_{E}(D)$ complements V in E. Consequently,

$$H^2(0^-(4, 2), V) = 0$$
.

7. Proof of Theorem 1, and Corollary 1, the case n = 1, 2. Consider part (a). For n = 1 the result holds, as $\operatorname{Aut}(D_s) \cong D_s$. For n = 2, $\operatorname{Out}(E_2) \cong 0^+(4, 2)$ is isomorphic to a wreath product $\sum_{s} \langle Z_2$. Now consider any extension

$$1 \longrightarrow \operatorname{Inn} (E_2) \longrightarrow B \longrightarrow 0^+(4, 2) \longrightarrow 1$$

with the same action as $Out(E_2)$ on $Inn(E_2)$. Let P be a Sylow 3subgroup of $B; P \subset 0_{2,3}(B)$. By the Frattini argument, $B = Inn(E_2) \cdot N_B(P)$. But P acting faithfully on $Inn(E_2)$ may not have a nontrivial fixed point. Thus, $\text{Inn}(E_2) \cap N_{\mathcal{B}}(P) = C_{\text{Inn}(E_2)}(P) = 1$. Thus, $N_{\mathcal{B}}(P)$ complements $\text{Inn}(E_2)$ in B, whence the extension is split. A similar argument shows that any extension of $\Omega^+(4, 2)$ by $\text{Inn}(E_2)$ is split.

Next, consider part (b). For n = 1 the result holds, as Aut $(Q_s) \cong \sum_4$ and $\sum_3 \subset \sum_4$ complements the normal four-group Inn (Q_s) . For $n = 2, 0^-(4, 2) \cong \sum_5$ and $\Omega^-(4, 2) \cong A_5$. The splitting in this case follows from Theorem 2.

The last assertion of Corollary 1 follows from the above.

8. Proof of Corollary 2. To prove Corollary 2, we choose $n \ge 3$ and work for a contradiction under the assumption that

 $1 \longrightarrow \operatorname{Inn} (E \circ Y) \longrightarrow A(E \circ Y) \longrightarrow \operatorname{Sp} (2n, 2) \longrightarrow 1$

is split. We claim that D, the subgroup of $A(E \circ Y)$ leaving invariant the subgroup $E \subset E \circ Y$ is isomorphic to Aut (E). Namely, any automorphism of Aut (E) can be extended to one of $E \circ Y$ by letting it act trivially on Y. Furthermore, every element in D is of this form, for if $\alpha, \beta \in D$ induce the same automorphism on E, then $\alpha\beta^{-1}$ is trivial on E and on Y, hence $\alpha\beta^{-1} = 1$. Clearly, $D \supset \text{Inn}(E \circ Y)$, which may be regarded as Inn(E) under our identification. Our hypothesis implies that the extension of D by $\text{Inn}(E \circ Y)$ is split. But this contradicts Theorem 1. The corollary is proven.

9. Proof of Theorem 3. Let k be a perfect field of characteristic 2, V a finite dimensional vector space over k, and b a nonsingular alternating form $V \times V \rightarrow k$. Let G be the symplectic group associated with b. In this section, we write functions and group actions on the left.

Recall that a derivation (or, a 1-cocycle) from G to V is a function $d: G \to V$ satisfying d(xy) = d(x) + xd(y), all $x, y \in G$. If q is a quadratic form on V whose associated bilinear form is b there is a derivation $d: G \to V$, where d(t) is defined by the condition

$$b(t(v), d(t)) = \sqrt{q(v) + q(t(v))}$$
, for all $v \in V$.

Note that, for fixed t, the right side is a linear functional in v. Since b is nonsingular, it identifies V with its dual, whence a unique vector d(t) is determined by the above condition.

We show that this d is a derivation. Let s, $t \in G$. By definition of d, we have

$$egin{aligned} b(st(v),\,d(st)) &= \sqrt{q(v)+q(st(v))} \;, \;\; ext{all} \;\; v \in V \ b(s(v),\,d(s)) &= \sqrt{q(v)+q(s(v))} \;, \;\; ext{all} \;\; v \in V \ b(t(v),\,d(t)) &= \sqrt{q(v)+q(t(v))} \;, \;\; ext{all} \;\; v \in V \;. \end{aligned}$$

In the second equation, replace the variable v by t(v), and in the third expression, replace b(t(v), d(t)) by b(st(v), sd(t)). Adding the three new equations, we get b(st(v), d(st) + d(s) + sd(t)) = 0 all $v \in V$, whence d(st) + d(s) + sd(t) = 0, as required. We shall see that in most cases, d is not a coboundary.

For $x \in V$, $x \neq 0$, let t_x be the transvection at x, i.e.,

$$t_x(v) = v + b(v, x)x .$$

Then,

$$egin{aligned} q(v) \,+\, q(t_x(v)) \,=\, q(v \,+\, t_x(v)) \,+\, b(v,\, t_x(v)) \ &=\, q(b(v,\, x)x) \,+\, b(v,\, v) \,+\, b(v,\, b(v,\, x)x) \ &=\, b(v,\, x)^2(1 \,+\, q(x)) \,\,, \end{aligned}$$

whence

$$d(t_x) = \sqrt{1+q(x)} x$$
.

If d were a coboundary, there would be a fixed $m \in V$ with d(t) = t(m) + m, all $t \in G$. Assume |k| > 2 or dim $(V) \ge 4$. Suppose $0 \ne y \in V$, q(y) = 0. From above, $y = d(t_y) = t_y(m) + m = b(m, y)y$, whence b(m, y) = 1, for all such y. Now, suppose q has isotropic subspaces of dimension $1/2 \dim(V)$. If |k| > 2, choose $c \in k, c \ne 0, 1$, and choose $y \ne 0$ with q(y) = 0. Then q(cy) = 0, but $b(m, cy) = cb(m, y) = c \ne 1$, contradiction. If dim $(V) \ge 4$, there are singular vectors x, y with q(x) = q(y) = q(x+y) = 0. Then $b(m, x+y) = b(m, x) + b(m, y) = 1 + 1 = 0 \ne 1$, contradiction. Thus, we may assume by changing q if necessary that d is not a coboundary if |k| > 2 or dim $(V) \ge 4$.

Now, take $k = F_2$, V of dimension 4. Since $G \cong \sum_6$, we have a nontrivial homomorphism $h: G \to F_2$. Define $f: G \times G \to V$ by

$$f(s, t) = h(t)d(s); s, t \in G$$
.

We show that this 2-chain is a 2-cocycle. We calculate (in characteristic 2)

$$\begin{split} f(s, t) &+ f(st, r) + sf(t, r) + f(s, tr) \\ &= h(t)d(s) + h(r)d(st) + h(r)sd(t) + h(tr)d(s) \\ &= h(t)d(s) + h(r)\{d(st) + sd(t)\} + \{h(t) + h(r)\}d(s) \\ &= h(t)\{d(s) + d(s)\} + h(r)\{d(st) + sd(t) + d(s)\} = 0 , \end{split}$$

so that f is a 2-cocycle.

We want to show that f is not a 2-coboundary, from which $H^2(\text{Sp}(4, 2), V) \neq 0$ will follow. Suppose there were a $g: G \to V$ so that f(s, t) = g(st) + sg(t) + g(s). Note that $0 = h(1) \cdot d(1) = f(1, 1) = g(1) + g(1) + g(1)$ implies g(1) = 0.

Let $0 \neq x \in V$ have q(x) = 0. Then $d(t_x) = x$ from above. Also, $t_x \notin G'$, so $h(t_x) = 1$. So,

$$egin{aligned} &x=h(t_x)d(t_x)=f(t_x,\,t_x)=g(1)\,+\,t_xg(t_x)\,+\,g(t_x)\ &=(t_x\,+\,1)g(t_x)=b(x,\,g(t_x))x \;. \end{aligned}$$

Thus, $b(x, g(t_x)) = 1$ and $g(t_x) \notin \langle x \rangle^{\perp}$ (where \perp denotes annihilator with respect to b).

Now, take q to be a quadratic form for which there are isotropic subspaces of dimension 2. Let x, y be distinct nonzero singular vectors with b(x, y) = 0. Then t_x and t_y commute. Now

$$d(t_x) = h(t_y)d(t_x) = g(t_xt_y) + t_xg(t_y) + g(t_x)$$
.

We then get

$$egin{aligned} d(t_x) \,+\, t_x g(t_y) \,+\, g(t_x) \,=\, g(t_x t_y) \,=\, g(t_y t_x) \ &=\, d(t_y) \,+\, t_y g(t_x) \,+\, g(t_y) \,\,, \end{aligned}$$

or

$$d(t_x) + (t_x + 1)g(t_y) = d(t_y) + (t_y + 1)g(t_x) ,$$

or

$$(1 + b(x, g(t_y))x = (1 + b(y, g(t_x))y)$$

Therefore, $b(y, g(t_x)) = 1$, since x and y are linearly independent.

Let W be the span of x and $g(t_x)$ in V. Then $W^{\perp} \subseteq \langle x \rangle^{\perp}$. But $x \notin W^{\perp}$ since $g(t_x) \in W$ and $g(t_x) \notin \langle x \rangle^{\perp}$. It follows easily that W is nonsingular under b. Since V has isotropic subspaces of dimension 2, there is a nonzero singular vector $y \in W^{\perp}$. But then $b(y, g(t_x)) = 0$ contradicts the last paragraph.

Therefore, f is not a 2-coboundary, as required. McLaughlin remarks that the cocycle d appeared in a different form in Dickson's work [7]. Now $H^1(\text{Sp}(4, 2), V) \neq 0$ and $H^1(\text{Sp}(4, 2), \mathbb{Z}_2) \cong \text{Hom}(\text{Sp}(4, 2), \mathbb{Z}_2)$ $\mathbb{Z}_2 \cong \mathbb{Z}_2$. Our definition of $f \in \mathbb{Z}^2(\text{Sp}(4, 2), V)$ as f(s, t) = h(t)d(s) is a cup-product construction [1], based on the (obvious) pairing $\mathbb{Z}_2 \otimes V \to V$. Note that the cocycle f restricted to G' is identically zero.

10. Proof of Theorem 4. We consider an arbitrary extension

 $(\neq)1 \longrightarrow V \longrightarrow B \longrightarrow \operatorname{Sp}(4, 2)' \longrightarrow 1$

of Sp $(4, 2)' \cong A_6$ by V, the usual 4-dimensional F_2 -vector space on which Sp (4, 2) acts. We will show (\neq) is split.

We know by Theorem 2, that (\neq) restricted to $\Omega^-(4, 2)$ is split. Let *D* be a subgroup of *E* mapping isomorphically onto $\Omega^-(4, 2) \subset$ Sp (4, 2)'. Since V is F_2 D-projective and injective. (By the Lemma in §6), V is likewise for F_2D_1 , D_1 any subgroup of D. If we take $|D_1| = 2$, and remark that all involutions of Sp (4, 2)' are conjugate, we get that (\neq) is split when restricted to any subgroup of order 2 in Sp (4, 2)'.

Let I be a maximal isotropic subspace of V, |I| = 4. The stabilizer K_1 of I in Sp (4, 2)' is isomorphic to \sum_4 . Let K be the preimage of K_1 in B, and let $R = 0_2(K)$. Note that a Sylow 3-subgroup P of K acts fixed point freely on R.

We claim R/I is elementary abelian. Now, P acts fixed point freely on R/I also. Since V/I is central in R/I, commutation is biadditive. Since $|R/V| = 2^2$, we have $|(R/I)| \leq 2$. But since (R/I)'is characteristic in R/I and P acts fixed point freely, (R/I)' = 1 follows. Thus, R/I is abelian. As pointed out above, every coset of V/I in R/I contains involutions. Thus, R/I is elementary abelian.

We have $P \subset 0_{2,3}(K)$ and $|K: 0_{2,3}(K)| = 2$. By the Frattini argument, we choose a 2-element $t \in N_K(P)$, $t \in 0_{2,3}(K)$. By the structure of K_1 , $t^2 \in V$, so $t^2 \in C_V(P) = 1$. Thus $\langle P, t \rangle \cong \sum_3$.

Since V/I is an irreducible $\langle P, t \rangle$ -module of dimension 2, the 2-part of $|\langle P, t \rangle|$, V/I is projective and injective over $F_2\langle P, t \rangle$ ([2], (6A)). So take $W \subset O_2(K)$ so that W/I is a $F_2\langle P, t \rangle$ -complement to V/I.

Since I is central in W, we may repeat the above arguments to get W elementary abelian and we may obtain an $F_2\langle P, t \rangle$ complement T to I in W. Clearly $\langle P, t, T \rangle$ intersects V trivially and covers K/V.

Thus, (\neq) splits when restricted to K_1 . Since $|\operatorname{Sp}(4, 2)': K_1|$ is odd, Gaschütz' Theorem implies that (\neq) is split. The theorem is proven.

11. Proof of Theorem 5. (a) Let M = C[E] be the complex group algebra of E. It is well-known ([9], 5.5.4) that E has precisely one faithful irreducible representation and it has dimension 2^n . Let Nbe the simple constituent of M corresponding to this representation. Now, Aut (E) permutes the irreducible representations of E, but Nmust be left invariant because it is the only faithful one. Thus, Aut (E) operates as automorphisms on the matrix algebra N. By the Skolem-Nöther Theorem, every automorphism of N is inner. ([13], p. 24).

For $\alpha \in \operatorname{Aut}(E)$, let $m(\alpha) \in N$ induce the same automorphism of N as α . We have $m(\alpha)m(\beta) = m(\alpha\beta)c(\alpha, \beta)$, for $\alpha, \beta \in \operatorname{Aut}(E)$, where $c(\alpha, \beta)$ is a scalar matrix. Thus

$$\alpha \longmapsto m(\alpha)$$

gives a projective representation of Aut(E). Conjugation by elements

of $E \subset M$ on N has the same effect as the action of the $m(\alpha), \alpha \in$ Inn (E). Since the representation $E \to N$ is irreducible and faithful, and not projectively equivalent to an ordinary representation of E/E', $\alpha \mapsto m(\alpha)$ is not equivalent to an ordinary representation of Aut (E).

By Schur ([15] (1907) or [12], 24.3), there is a covering group K of Aut (E), a subgroup $C \subseteq \mathbb{Z}(K) \cap K'$, and an isomorphism ϕ so that the diagram below commutes

$$\begin{array}{ccc} K/C & \stackrel{\phi}{\longrightarrow} GL(2^{n}, C) \\ & & \downarrow \\ Aut (E) & \stackrel{m}{\longrightarrow} PGL(2^{n}, C) \end{array}.$$

We shall show that, for $n \ge 5$, C = 1 and that K is our desired group H. Following this, the case $n \le 4$ will be treated.

Let $G = \operatorname{Aut}(E)$ and suppose $n \geq 5$. Set A = Z(K). Then, $A \subseteq K'$ and $K/A \cong G$. Let $R = \operatorname{Inn}(E) \triangleleft G$, and let \tilde{R} be the extension of R induced by K. Set $B = A \cap \tilde{R}'$ and let L = K/B. Now, $0^{\epsilon}(2n, 2)$ has trivial multiplier ([17] and preliminary result (11) of [10]). Also, $H^1(0^{\epsilon}(2n, 2), V) = 0$ for $n \geq 4$ and V the standard module [16]. Since V is self dual, this last fact implies that $\operatorname{Ext}(V, \mathbb{Z}_2) \cong$ $\operatorname{Ext}(\mathbb{Z}_2, V) \cong H^1(0^{\epsilon}(2n, 2), V) = 0$. All this, together with the irreducibility of G/R on R, implies that $(A/B) \cap L' = 1$. Since $A \subseteq K'$, we get A = B. Since the multiplier of an elementary abelian group is elementary abelian [12], B is elementary. We wish to show |B| = 2.

Suppose B_1 is a hyperplane of B. Then the squaring map from R/B_1 into $B/B_1 \cong \mathbb{Z}_2$ induces a quadratic form q_1 on $\tilde{R}/B \cong R$ which is preserved by G/R. Let B_1 and B_2 be distinct hyperplanes and q_1 and q_2 the associated forms. We claim that q_1 and q_2 are "distinct", i.e., that the following does not happen: for every $x \in R$, $q_1(x) = 1$ if and only if $q_2(x) = 1$. Namely, if the latter does hold, then the squares in R generate a proper subgroup of B, contradiction. This shows that if $0^{\epsilon}(2n, 2)$ preserves a unique quadratic form on V, then $|B| \leq 2$ follows.

Suppose q and q' are quadratic forms with the same associated bilinear form b. Then, the groups which preserve q and q' are subgroups of the symplectic group associated with b, and they are equal if and only if q = q' (as is well-known). So, to get $|B| \leq 2$, it suffices to show that $0^{\epsilon}(2n, 2)$ preserves a unique bilinear form, i.e., that $\dim_{F_2} \operatorname{Hom}_{0^{\epsilon}(2n,2)}(V \otimes V, F_2) = 1$. But since V is a self dual module, we have (dropping subscripts), $\operatorname{Hom}(V \otimes V, F_2) \cong$ $\operatorname{Hom}(V, \operatorname{Hom}(V, F_2)) \cong \operatorname{Hom}(V, V)$, and the latter object has dimension 1, because (for $n \geq 2$) V is an absolutely irreducible module (as is easily proven, say, by induction on n; or see [18]).

We now have $|B| \leq 2$. Since $Z(K) \neq 1$, this forces C = 1 and shows that the covering group $K = K(n, \varepsilon)$ has the properties required of H, for $n \geq 5$, $\varepsilon = \pm$. We turn to the case $n \leq 4$. Fix $K_0 = K(m, \delta)$, for $m \geq 5$, and some sign δ . Choose a nonsingular subspace W of R = Inn(E), so that the annihilator in R of W has order 2^{2n} , type ε . Let \tilde{W} be the preimage of W in K_0 ; \tilde{W} is an extra-special group of type $\varepsilon \delta$. Let J be the centralizer of \tilde{W} in K_0 . We have $J \cap \tilde{W} =$ $Z(\tilde{R}) = Z(\tilde{W}), J\tilde{W} = \tilde{R}$, and J induces the identity on \tilde{W} and the full orthogonal group on $J \cap \tilde{R}/J \cap Z(\tilde{R})$. This suffices to show that we may take J to be our H for this pair n, ε .

For $n \geq 5$, it is clear that $K(n, \varepsilon)$ has an irreducible, faithful complex representation of degree 2^n . For $n \leq 4$, we argue using the notation of the last paragraph. The representation of degree 2^m , when restricted to \widetilde{W} , is the direct sum of 2^n equivalent faithful irreducible representations of \widetilde{W} , each of dimension 2^{m-n} . Thus, $J = C_{K_0}(\widetilde{W})$ acts in 2^n dimensions, and this action is easily seen to be faithful and irreducible.

(b) Every irreducible representation of $E \circ Y$ may be expressed as a product of such of E and of Y. ([9], 3.7.1). Now, E has precisely one irreducible faithful representation of dimension 2^n , and Yhas two such, each of degree 1. Thus $E \circ Y$ has precisely two faithful irreducible representations, each of dimension 2^n .

By imitating the argument of part (a), $A(E \circ Y)$ permutes the irreducible constituents of $C[E \circ Y]$, hence permutes the two constituents N_1, N_2 corresponding to faithful representations. But since $A(E \circ Y)$ centralizes Y, it leaves each N_i invariant. As in (a), this gives a projective representation of $A(E \circ Y)$ of the required degree and the group H_0 is constructed in a similar way (we need the fact that Sp (2n, 2) has trivial multiplier for $n \geq 4$ [17]).

It is clear from the construction that these two representations are related by the action of Aut $(E \circ Y)$ on the normal subgroup $A(E \circ Y)$. Also, complex conjugation interchanges these two representations, since each restricted to E has rational trace.

(c) Our argument may be refined as follows. Let F be a splitting field for X = E (resp. $E \circ Y$). We may replace C[X] by F[X] to get a projective representation of $W = \operatorname{Aut}(X)$ (resp. A(X)) over F, i.e., our map m can be made to satisfy $m(\alpha)m(\beta) = c(\alpha, \beta)m(\alpha\beta)$, where the m() are matrices with entries in F and $c(\alpha, \beta) \in F$. Thus, the image m(W) in $PGL(2^n, C)$ actually lies in $PGL(2^n, F) \subseteq PGL(2^n, C)$. Then, from the diagram, $\phi(W) \subseteq C^{\times} \cdot GL(2^n, F)$, where C^{\times} is identified with the scalar matrices.

Now, we have $\phi(W') = \phi(W)' \subseteq (C^{\times} \cdot GL(2^n, F))' = SL(2^n, F)$. Thus,

on 2^n -dimensional linear representation for W' may be written in the field F.

Now, let W_0 be H or H'E. If ψ denotes the character of the unique faithful representation of E, then, evidently, if χ is irreducible character of W_0 for which $\chi|_E$ is faithful, $\chi|_E$ is a multiple of ψ . For such χ , a theorem of Clifford states that $\chi = \xi \eta$, where ξ , η are projective characters of W_0 and $E \subseteq \ker(\xi), \eta(1) - \psi(1)$. In fact, the proof of (a) and the proof in [5] (page 351) shows that we may take ξ and η to be characters of ordinary representations, and we may even take η to be the character of the 2^n -dimensional representation we have constructed. If we let ξ be a variable running over the irreducible characters of W_0/E , we can see that all the $\xi\eta$ are distinct and form the set of faithful irreducible characters of W_0 by using the fact that $|W_0|$ is the sum of the squares of the degrees of the irreducible characters of W_0 .

Similar arguments prove the statement for $W_0 = H_0$ or $H'_0 E$. There are two choices for η to consider in this case, however.

12. Proof of Corollary 3. It suffices to prove the second extension does not split. Suppose it does. Let $G \subset A(E \circ Y)$, $G \cong \text{Sp}(4, 2) \cong \sum_{6}$. By Theorem 5(b), there is a group H_{0} and an exact sequence

$$1 \longrightarrow Z_2 \longrightarrow H_0 \xrightarrow{\pi} A(E \circ Y) \longrightarrow 1$$
.

Let G_0 be the preimage of G in H_0 . Since H_0 has a faithful complex representation of degree 4, so does G_0 .

Since \sum_{6} has no faithful ordinary irreducible representations of degree less than 5 [5], G_0 is isomorphic to a covering group of \sum_{6} (see [12], 24.3).

We identify $E \circ Y$ with $0_2(H_0)$. Denote images modulo Y by bars. Note that Inn $(E \circ Y)$ inherits from $E \circ Y$ an alternating form stabilized by G. Let I be a subgroup of $E \circ Y$ containing Y isomorphic to $Z_2 \times Z_2 \times Z_4$. Then \overline{I} is a maximal isotropic subspace of Inn $(E \circ Y)$ and $|\overline{I}| = 4$. The stabilizer K in G of \overline{I} is isomorphic to $\sum_4 \times Z_2$. Let K_0 be the preimage in G_0 of K. Since the Sylow 2-subgroups of G'_0 are quaternion of order 16, we have $K'_0 \cong SL(2,3)$. Note, $|0_2(K_0)| = 16$.

Now, K_0 acts on I while centralizing Y. Since K_0 induces SL(2, 2)on $\overline{I}, 0_2(K_0)$ stabilizes the chain $I \supset Y \supset 1$. We claim that $0_2(K_0)$ stabilizes the chain $I \supset E' \supset 1$. First, notice that every coset of Yin I contains an element of order 2. Now, let $w \in 0_2(K_0), u \in I$, and write u = vy, where $y \in Y$ and $v^2 = 1$. Since I is abelian, and $0_2(K_0)$ centralizes Y, we have $[u, w] = [vy, w] = [v, w]^y[y, w] = [v, w]$ and $[u, w]^2 = [v, w]^2 = [v^2, w] = 1$. Thus, $[I, 0_2(K_0)]$ is contained in E', the subgroup of order 2 of Y. This proves the claim. Commutation induces a map $0_2(K_0) \rightarrow \text{Hom}(I/Y, E')$, and the latter group has order 4. So, the kernel R of this map has order at least 4. Note that $R \cap I \subseteq 0_2(K_0) \cap I = E'$. Let R_1 be an abelian subgroup of R of order at least 4. Then, $\langle R_1, I \rangle$ is an abelian group of order

$$|\,R_{\scriptscriptstyle 1}\cap\,I|^{-{\scriptscriptstyle 1}}|\,R_{\scriptscriptstyle 1}||\,I| \ge rac{1}{2} \cdot 4 \cdot 16 = 25$$
 .

Since $R/R \cap E'$ is elementary abelian, $\langle R_1, I \rangle / E'$ is elementary abelian of order at least 2⁴, whence $\langle R_1, I \rangle$ contains a subgroup L which is elementary abelian of order 2⁴.

We claim that in our representation of degree 4, every element of H_0 acts with determinant 1. Since G_0 covers $H_0/H'_0 \cong \mathbb{Z}_2$, it suffices to prove the statement for elements of G_0 . Suppose there are elements of G_0 acting with determinant -1. Since G contains an elementary abelian group of order 8, the Sylow 2-subgroups of G_0 are not (generalized) quaternion. But, as those of G'_0 are, there is an involution $u \in G_0 \backslash G'_0$. If the matrix representing u is diagonalized, it has ± 1 's on the diagonal. Since u acts with determinant -1, these eigenvalues are

$$\{1, -1, -1, -1\}$$
 or $\{-1, 1, 1, 1\}$.

Now $(u)\pi \in G$ has centralizer $\langle (u)\pi \rangle \times M$, $M \subset G'$, $M \cong \sum_{i}$. Let M_{i} , resp. M_{2} , denote the preimage in G_{0} of M, resp. M'. Since $(u)\pi$ centralizes M, u induces a central automorphism of M_{1} , but centralizes $M_{2} \cong SL(2, 3)$.

Since M_2 commutes with u, M_2 preserves the eigenspaces of u. This forces M_2 to have a 1-dimensional constituent, whence M'_2 acts trivially on this constituent. However, $E' \subset M'_2$ and E' acts as the scalar -1 in this 4-dimensional representation, contradiction.

We have just shown that every element of H_0 acts with determinant 1. The same must hold for $L \subset H_0$. But it is impossible for an elementary abelian group of order 2⁴ to act faithfully with determinant 1 in 4 dimensions.

This final contradiction proves that the complement G does not exist. The corollary is established.

13. Proof of Theorem 1 (a), the case n = 3. Let H be the group of Theorem 5(a), associated with $E = E_3$. Set $H_1 = H'$. We identify E with $0_2(H_1) = 0_2(H)$. We have $E' = Z(H_1) = Z(H)$, $H_1/E \cong \Omega^+(6, 2) \cong A_8$, $H_1/E' \cong A(E)$.

Suppose that

$$(*) \quad 1 \longrightarrow E/E' \longrightarrow H_1/E' \longrightarrow H_1/E \longrightarrow 1$$

is the split extension. Take $H_2 \subset H_1$ so that $H_1 = EH_2$ and $E \cap H_2 = E'$. Then $H_2 \cong \mathbb{Z}_2 \times A_8$ or \hat{A}_8 , the covering group of A_8 .

Let $a(t) \in H_2$ be a representative for $t \in H_2/E'$. We assume a(1) = 1. In the case $H_2 \cong A_8 \times \mathbb{Z}_2$, we take all the a(t) to lie in H'_2 . Every $g \in H_1$ may be expressed uniquely as a product $g = xa(t), x \in E, a(t) \in H_2$. If $g^2 = 1$, exactly one of the possibilities below must hold:

(i)	x = 1 $a(t$	z) = 1	
(ii)	x = 1 $ a(t) $	=2	
(iii)	x = e $a(t$) = 1	
(iv)	$x = e \qquad a(t) $	=2	
(v)	$ x = 2$, $x \notin \langle e \rangle$	$\rangle \qquad x^t = x$	a(t) = 1
(vi)	$ x = 2$, $x \notin \langle e \rangle$	$\rangle \qquad x^t = x$	a(t) =2
(vii)	$ x = 2, x \in \langle e \rangle$	$\rangle \qquad x^t = xe$	$a(t)^{\scriptscriptstyle 2} = e$
(viii)	x = 4	$x^t = x$	$a(t)^{\scriptscriptstyle 2}=e$
(ix)	x = 4	$x^t = xe$	a(t) =2 .

For any group G that follows, let $s(G) = |\{y \in G | y^2 = 1\}|$. We count $s(H_1)$ in two different ways. First, we analyze the contribution types (i) through (ix) to $s(H_1)$. In particular, we show that the contribution of each of types (i) and (iii) is 1 and that of each other type is a multiple of 5. We point out that for all $x \in E$, and all $a(t) \in H_2$, we have that $C_{H_2}(xa(t)) \subseteq N_{H_2}(\langle a(t), e \rangle)$, and in case $H_2 \cong A_8 \times \mathbb{Z}_2$, we have $N_{H_2}(\langle a(t), e \rangle) = C_{H_2}(a(t))$.

Assume $H_2 \cong A_8 \times \mathbb{Z}_2$; then $H'_2 = \{a(t) \mid t \in H_2/\mathbb{Z}(H_2)\}$. For types (i) and (iii), we get one g each. For each of (ii) and (iv), we get as many g as involutions in A_8 ; the total is $2\{3 \cdot 5 \cdot 7 + 2 \cdot 3 \cdot 5 \cdot 7\}$. For (v), (vi), and (vii), note that there are $2 \cdot 35$ involutions $x \in E \setminus \langle e \rangle$. Let m be the number of $a(t) \in H_2$ centralizing x with |a(t)| = 2. There are no g of type (vii) since $H'_2 \cong A_8$. Thus, the contribution of types (v), (vi) and (vii) is 70 $\{1 + m\}$. No g of type (viii) occurs since $H'_2 \cong A_8$. For (ix), note that there are $2 \cdot 28$ elements of order 4 in E. The involutions $a(t) \in H_2$ inverting x lie in D, the subgroup of H'_2 stabilizing $x \langle e \rangle$. Since $D \cong \text{Sp}(4, 2) \cong \sum_6$, every nonidentity 2-element in D has D-conjugacy class of size divisible by 5. Since the set of a(t) inverting x is a union of D-conjugacy classes, the number of such a(t) is divisible by 5.

Adding up these contributions, we get $s(H_1) = 2 \pmod{5}$ in the case $H_2 \cong A_8 \times Z_2$.

Assume $H_2 \cong \hat{A}_8$. Using Schur's generators and relations for A_8 [15] (1911), we find that an involution in A_8 is represented in \hat{A}_8 by

an element of order 4 if and only if it can be written as the product of two disjoint transpositions. For types (i), (iii), we get one g each. For each of (ii), (iv), we get 3.5.7 involutions. The contribution of types (v), (vi) and (vii) is a multiple of 70. For each of (viii) and (ix), the contribution is a positive multiple of 5.

So, adding the contribution, we get $s(H_1) \equiv 2 \pmod{5}$ in the case $H_2 \cong \hat{A}_8$ as well.

Next, we count $s(H_1)$ in a different way, using a theorem of Frobenius and Schur, [8], §3. Namely, if G is a finite group, then $s(G) = \sum \nu(\chi)\chi(1)$, where the sum ranges over the irreducible characters χ of G,

$$\mathcal{V}(\chi) = rac{1}{|G|} \sum \chi(y^2)$$
 (sum over all $y \in G$), and where $\mathcal{V}(\chi) = 1$

if and only if χ is afforded by a real representation, $\nu(\chi) = -1$ if and only if χ is real but not afforded by a real representation, $\nu(\chi) = 0$ otherwise.

The proper normal subgroups of H_1 are $E = 0_2(H_1)$ and E'. We have

$$s(H_1) = \lambda + \mu$$

where

$$\lambda = \sum_{E' \subseteq \ker \chi} \nu(\chi) \chi(1)$$
 and $\mu = \sum_{1=\kappa \in \chi} \nu(\chi) \chi(1)$

so that $\lambda = s(H_1/E')$.

Consider those χ occuring in μ . Since $\chi|_E$ is a sum of characters faithful on E, the arguments of §11 show that $\chi = \xi \eta$, where η is the character of the 16-dimensional representation constructed in §11, and ξ is any irreducible character of H_1 with kernel containing E.

Now, by the results of §11, η is afforded by a rational (hence, real) representation, and so $\nu(\eta) = +1$. A study of [8], §3, shows that we can get $\nu(\chi) = \nu(\xi\eta) = \nu(\xi)$. Therefore,

$$\begin{split} \mu &= \sum_{\ker \chi = 1} \nu(\chi) \chi(1) = \sum_{\ker \xi \supseteq E} \nu(\xi) \xi(1) \eta(1) \\ &= \eta(1) \sum_{\xi} \nu(\xi) \xi(1) = 16 \ s(H_1/E) = 16 \ s(A_8) \\ &= 16 \ \{1 + 3 \cdot 5 \cdot 7 + 2 \cdot 3 \cdot 5 \cdot 7\} = 16 \ (316) \ . \end{split}$$

We now have the value of μ . We next calculate the value of $\lambda = s(H_i/E')$ under the assumption that (*) splits.

Denote images under $H_1 \rightarrow \overline{H}_1 = H_1/E'$ by bars. We have $\overline{H}_1 = \overline{E}\overline{H}_2$, a semidirect product. Note that $\overline{H}_2 \cong A_8$ has two classes of involutions, represented by, say, h and k. We choose notation so

that, in the usual representation of A_8 on 8 letters, h fixes no letter and k fixes four. Then $|C_{\overline{H}_2}(h)| = 2^6 \cdot 3$, $|C_{\overline{H}_2}(k)| = 2^5 \cdot 3$. In particular, h is central in a Sylow 2-subgroup and k is not.

We claim that, for any involution $y \in \overline{H}_2$, $|C_{\overline{E}}(y)| = 2^4$. Let $v \in \overline{E}$ be a nonzero isotropic vector. Replacing h by a conjugate if necessary, we may assume $h \in 0_2(S)$, where S is the subgroup of \overline{H}_2 stabilizing $\langle v \rangle$. Since $0_2(S)$ is elementary abelian of order 16, it does not act regularly on the 8 letters. Thus, we may assume $k \in 0_2(S)$ as well.

Let \overline{E}_0 be the annihilator of $\langle v \rangle$ in \overline{E} under the bilinear form. Then $0_2(S)$ acts trivially on $\overline{E}_0/\langle v \rangle$. Thus, any $y \in 0_2(S)^{\sharp}$ centralizes a hyperplane of \overline{E}_0 , whence $|C_{\overline{E}}(y)| \geq 2^4$. On the other hand, \overline{H}_2 contains no elements which act as orthogonal transvections on \overline{E} . Thus, $|C_{\overline{E}}(y)| = 2^4$.

Setting y = h or k, we get our claim.

We can now calculate $s(\bar{H}_1)$. Every $g \in \bar{H}_1$ can be written g = xy, $x \in \bar{E}, y \in \bar{H}_2$. We have $g^2 = 1$ if and only if $x^2 = y^2 = [x, y] = 1$. We have shown that if $y \in \bar{H}_2$ is an involution, $|C_{\bar{E}}(y)| = 2^4$. Since the classes of involutions of \bar{H}_2 are represented by h and k we have

$$s(ar{H}_1) = |ar{E}| + 2^4 \{3.5.7 + 2.3.5.7\} = 16\{4 + 105 + 210\}$$

= 16 (319).

It follows that $s(H_1) = \lambda + \mu = 16 (319 + 316) = 16(835)$.

From our first count, we have $s(H_i) \equiv 2 \pmod{5}$, but here we have shown that $s(H_i) \equiv 0 \pmod{5}$. This contradiction shows that (*) is not split. Therefore, Theorem 1(a) holds in the case n = 3 as well.

This completes the proofs of all the Theorems.

The Supporting Institutions listed above contribute to the cost of publication of this Journal, but they are not owners or publishers and have no responsibility for its content or policies.

Mathematical papers intended for publication in the *Pacific Journal of Mathematics* should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Items of the bibliography should not be cited there unless absolutely necessary, in which case they must be identified by author and Journal, rather than by item number. Manuscripts, in duplicate if possible, may be sent to any one of the four editors. Please classify according to the scheme of Math. Rev. Index to Vol. **39**. All other communications to the editors should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints are provided free for each article; additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966. Regular subscription rate: \$48.00 a year (6 Vols., 12 issues). Special rate: \$24.00 a year to individual members of supporting institutions.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley, California, 94708.
