PERIODIC POINTS ON TORI

BENJAMIN HALPERN

We prove the following theorem.

THEOREM 1. Given a continuous map $f: T^n \to T^n$ of the *n*-dimensional torus into itself. Each map homotopic to f has an infinite number of periodic points if and only if the Lefschetz numbers of the iterates $L(f^m)$, $m=1, 2, \cdots$, are unbounded.

The "if" direction of Theorem 1 follows from a theorem of Brooks, Brown, Pak, and Taylor [1]. Let N(f) denote the Nielsen number of the map f. Recall that each map homotopic to f must have at least N(f) distinct fixed points.

THEOREM 2. (Brook, Brown, Pak, and Taylor [1]). If $f: T^n \to T^n$ is a continuous map, then N(f) = |L(f)|.

The converse direction of Theorem 1 is deduced from the more precise result, Theorem 3.

DEFINITION 1. Given a map $f: T^n \to T^n$. Let $\lambda_1, \dots, \lambda_n$ be the characteristic values of $H_1(f): H_1(T^n) \to H_1(T^n)$. If λ_i is not a root of unity, then set $a_{im} = |1 - \lambda_i^m|$. If λ_i is a root of unity, then let N be such that $\lambda_i^N = 1$ and $\lambda_i^m \neq 1$ for $1 \leq m < N$ (i.e., λ_i is a primitive Nth root of unity), and set

$$a_{im} = egin{cases} |\mathbf{1} - \lambda_i^m| & ext{if} \ m
ot \equiv 0 mm{ mod} N \ \sum\limits_{q \mid N} |\mathbf{1} - \lambda_i^q| & ext{if} \ m \equiv 0 mm{ mod} N \ . \end{cases}$$

Set $a_m(f) = \prod_{i=1}^n a_{im}$.

THEOREM 3. For each map $f: T^n \to T^n$ there exists a smooth map g homotopic to f such that for $m \ge 1$,

$$\#\{x \in T^{n} \mid g^{m}(x) = x\} \leq a_{m}(f) .$$

Since $L(f^m) = \prod_{i=1}^n (1 - \lambda_i^m)$, we see that $\# \{x \in T^n \mid g^m(x) = x\} = N(f)$ for all *m* such that $\lambda_i^m \neq 1$ for all *i*. From Theorems 2 and 3, one may also deduce similarities between the asymptotic behaviors of $P_m = \# \{x \in T^n \mid g^m(x) = x\}$ and $Q_m = \max \{N(f^r) \mid 1 \leq r \leq m\}$.

In the process of proving Theorem 3 we establish a general result, Theorem 4, which concerns periodic points for maps homotopic to periodic maps.

THEOREM 4. Given a smooth compact connected manifold M of dimension $m \ge 2$, and a smooth map $f: M \to M$ such that $f^N = 1_M$ for some $N \ge 2$, and $f(x_0) = x_0$ for some $x_0 \in M$. Also suppose P = $\{x \in M \mid f^r(x) = x \text{ for some } r, 1 \le r < N\}$ is finite. Then there exists a smooth map $g: M \to M$ which is homotopic to f and such that P =the set of all periodic points of g, and $g \mid P = f \mid P$.

When Theorem 4 is specialized to tori, it gives a map q homotopic to the given periodic map $f: T^n \to T^n$, whose numbers of periodic points of various periods are exactly the lower bounds implied by Theorem 3 for an arbitrary map $f: T^n \to T^n$ is proved Theorem 2. by homotoping f to a map g which with a "change of coordinates" takes the form g: $T^n = T^k \times T^{n-k} \rightarrow T^k \times T^{n-k} = T^n$, g(x, y) = (a(x), r(x, y))where $a: T^k \to T^k$ is periodic. We homotopy a to an \overline{a} according to Theorem 4 and then, using an induction hypothesis we homotopy ron the sets $\{x\} \times T^{n-k}$ for x a periodic point of \overline{a} . This gives a map whose periodic points are the same as a map of the form $\bar{a} \times \bar{b}$: $T^{*} \times$ $T^{n-k} \to T^k \times T^{n-k}$ where $\bar{a}: T^k \to T^k$ and $\bar{b}: T^{n-k} \to T^{n-k}$. This is sufficient to prove Theorem 3 by induction, but it gives a map with possibly more periodic points than the lower bound set in Theorem 2. In special cases the lower bound in Theorem 2 can be achieved by refinements in the technique outlined above. So we make the following conjecture.

Conjecture. Given a map $f: T^n \to T^n$. Then there exists a smooth map g homotopic to f such that $\#\{x \in T^n \mid x \text{ is a periodic point of } g \text{ of least period } m\} = r_m$ where $r_1 = |L(f)|$ and for $q \ge 2$

This work was motivated by a question of Shub and Sullivan which appears on page 140 of Hirsch [3]. Shub and Sullivan ask whether every map homotopic to $g: T^2 \to T^2$ must have an infinite number of periodic points where g is the map covered by the linear map $\overline{g}: \mathbb{R}^2 \to \mathbb{R}^2$ whose matrix is $\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$. Since the Lefschetz numbers $L(g^*)$ are easily seen to be unbounded, a positive answer follows from the theorem of Brooks, Brown, Pak, and Taylor, Theorem 2. An elementary, transparent proof of a special case of Theorem 2 is presented in Proposition 1.

2. Preliminaries. Denote the integers by Z, the rationals by

Q, and the reals by R. For each $a \in R^n$ let $T_a: R^n \to R^n$ denote the translation by a, $T_ab = b + a$ for $b \in R^n$. Set $\mathscr{T} = \{T_a \mid a \in Z^n\}$. Let $\pi: R^n \to T^n$ denote the usual covering map which identifies T^n with R^n/\mathscr{T} . Recall that an $n \times n$ matrix A is unimodular provided it has integer entries and det $A = \pm 1$, or equivalently, it has integer entries and an inverse with integer entries. Clearly, the rows of a matrix A with integer entries form a basis for the module Z^n over Z if and only if A is unimodular.

We will use the form of Nielsen fixed point theorem which states that if $f: X \to X$ is a continuous map of a compact manifold X into itself, then each map g homotopic to f must have at least N(f) fixed points, where N(f) is the Nielsen number of f. Furthermore, N(g) =N(f), (Brown [2]). The Nielsen number N(f) is defined as follows. First an equivalence relation \sim is defined on the set F of fixed points of f. Two fixed points $x, y \in F$ are equivalent, $x \sim y$, provided there is a path γ in X from x to y such that $f \circ \gamma$ is end points fixed homotopic to γ . The set of equivalence classes F/\sim is known to be finite and each equivalence class is compact.

Using a fixed point index I, such as defined in [2] we may assign an index i(A) to each $A \in F/\sim$ by setting i(A) = I(U) for any open set U such that $F \cap U = A$. The Nielsen number N(f) is the number of $A \in F/\sim$ such that $i(A) \neq 0$. If A is a singleton $\{x\}$, then $i\{x\}$ is the usual index of an isolated fixed point of f and consequently if fis differentiable and $1 - df_x$ is nonsingular, then $i\{x\} = \pm 1$ as $\det (1 - df_x)$ is positive or negative.

Let $e^1 = (1, 0, \dots, 0)$, $e^2 = (0, 1, \dots, 0)$, etc., denote the standard basis for \mathbb{R}^n . Set $\beta_i(t) = \pi(te^i)$ and $\alpha_i = [\beta_i] \in \pi_1(T^n, *)$, where $* = \pi(0)$. Then $\alpha_1, \dots, \alpha_n$ form a basis for $\pi_1(T^n, *)$. Since the Hurewitz homomorphism $\rho: \pi_1(T^n, *) \to H_1(T^n)$ is an isomorphism, we can identify $\pi(T^n, *)$ with $H_1(T^n)$ via ρ and consider $\alpha_1, \dots, \alpha_n$ as a basis for $H_1(T^n)$, which we shall call the standard basis of $H_1(T^n)$. If $L: \mathbb{R}^n \to \mathbb{R}^n$ is a linear map, we denote its matrix with respect to the standard basis by \overline{L} and define it by $L(e^i) = \sum_j \overline{L}_{ji}e^j$. Throughout this paper we will consider \mathbb{R}^n to be a space of column vectors. Then \overline{L} satisfies $L(v) = \overline{L}v$ for all v in \mathbb{R}^n .

Consider the case where $\overline{L}_{jk} \in \mathbb{Z}$ for all j, i. Then for $a \in \mathbb{Z}^n$, $La = b \in \mathbb{Z}^n$. Since $L \circ T_a = T_b \circ L$, we see that L induces a map $L': T^n \to T^n$. We say that L covers L'. It is a straightforward verification that the matrix of $H_1(L'): H_1(T^n) \to H_1(T^n)$ with respect to the standard basis is equal to \overline{L} . Since T^n is covered by \mathbb{R}^n , T^n is an Eilenberg-MacLane space, $T^n = K(\mathbb{Z}^n, 1)$. Hence the homotopy class of a map $f: T^n \to T^n$ is determined by the homomorphism $H_1(f): H_1(T^n) \to H_1(T^n)$. We sum up these observations in the following lemma. LEMMA 1. Each map $f: T^n \to T^n$ is homotopic to a map $g: T^n \to T^n$ which is covered by a linear map $\overline{g}: \mathbb{R}^n \to \mathbb{R}^n$ whose matrix is the same as the matrix of $H_1(f): H_1(T^n) \to H_1(T^n)$.

LEMMA 2. If $f: T^n \to T^n$ is covered by a linear map $A: \mathbb{R}^n \to \mathbb{R}^n$, $f \circ \pi = \pi \circ A$, and 1 is not a characteristic root of A, then the fixed points are isolated, they all have the same index, and the number of them is |L(f)|.

Proof. Let x be a fixed point of f. Using an appropriate restriction of $\pi: \mathbb{R}^n \to T^n$ for a coordinate system about x, we see that df_x expressed in these coordinates is A. Since det $(1 - A) = \prod_{i=1}^n (1 - \lambda_i)$, where $\lambda_1, \dots, \lambda_n$ are the characteristic roots of A, we see that det $(1 - A) \neq 0$. Hence x is an isolated fixed point. Therefore, $i(x) = \pm 1$ as det (1 - A) is positive or negative, and so i(x) is independent of x. The Lefschetz fixed point formula asserts that the sum of the i(x) as x ranges over the fixed points of f is L(f). Hence the number of fixed points is |L(f)|.

PROPOSITION 1. Given a map $f: T^n \to T^n$ such that 1 is not a characteristic root of $H_1(f): T^n \to T^n$. Then N(f) = |L(f)|.

Proof. By Lemma 1 and the homotopy invariance of N(f), we see that we may assume that f is covered by a linear map $A: \mathbb{R}^n \to \mathbb{R}^n$ and that 1 is not a characteristic root of A. From Lemma 2 we know that the set F of fixed points of f satisfies # F = |L(f)|, and $i(x) \neq 0$ for each $x \in F$. To prove the present proposition it is sufficient to show that if $x, y \in F$, and $x \neq y$, then x is not Nielsen equivalence class and their number, # F = |L(f)|, will be equal to N(f) by the definition of N(f).

Assume $x, y \in F$, $x \neq y$, and $x \sim y$. Then there is a path γ in T^* from x to y such that γ is end points fixed homotopic to $f \circ \gamma$. Let $\tilde{\gamma}: I \to \mathbb{R}^*$ be a lift of $\gamma, \pi \circ \tilde{\gamma} = \gamma$, going from $\tilde{\gamma}(0) = \tilde{x}$ to $\tilde{\gamma}(1) = \tilde{y}$. Then $A \circ \tilde{\gamma}$ covers $f \circ \gamma$, since $\pi \circ A = f \circ \pi$. Set $a = \tilde{x} - A(\tilde{\gamma}(0)) = \tilde{x} - A(\tilde{x})$. Since $\pi(A(\tilde{x})) = f(\pi(\tilde{x})) = f(x) = x$ and $\pi(\tilde{x}) = x$ we deduce that $a \in \mathbb{Z}^*$. Then $\pi \circ T_a = \pi$ and so $T_a \circ A \circ \tilde{\gamma}$ is also a lift of $f \circ \gamma$, $\pi \circ T_a \circ A \circ \tilde{\gamma} = \pi \circ A \circ \tilde{\gamma} = f \circ \pi \circ \tilde{\gamma} = f \circ \gamma$. Also note that $T_a \circ A \circ \tilde{\gamma}(0) = A(\tilde{\gamma}(0)) + a = \tilde{x} = \tilde{\gamma}(0)$. Since γ is end point fixed homotopic to $f \circ \gamma$, we have $T_a \circ A \circ \tilde{\gamma}(1) = \tilde{\gamma}(1)$. Therefore $\tilde{\gamma}(1) - \tilde{\gamma}(0) = T_a A \tilde{\gamma}(1) - T_a A \tilde{\gamma}(0) = (A \tilde{\gamma}(1) + a) - (A \tilde{\gamma}(0) + a) = A(\tilde{\gamma}(1) - \tilde{\gamma}(0))$. From $x \neq y$ and $\pi \tilde{\gamma}(0) = x$ and $\pi(\tilde{\gamma})(1) = y$, we conclude that $\tilde{\gamma}(0) \neq \tilde{\gamma}(1)$. Hence $\tilde{\gamma}(1) - \tilde{\gamma}(0)$ is an eigenvector of A with eigenvalue 1, a contradiction.

2. Algebraic lemmas.

LEMMA 3. Given $v = (v_1, \dots, v_n) \in \mathbb{Z}^n$, $n \ge 1$, such that g.c.d. $(v_1, \dots, v_n) = 1$, where g.c.d. stands for greatest common divisor. Then there exist v^2 , v^3 , \dots , $v^n \in \mathbb{Z}^n$ such that v, v^2 , \dots , v^n form a basis for \mathbb{Z}^n .

Proof. We use induction on n. For n = 1 we must show that $\{v\}$ is a basis for Z^1 , i.e., that $v = \pm 1$. But this follows from the fact that g.c.d. (v) = 1.

Now suppose n > 1 and that the lemma holds for n - 1. If $v_1 = v_2 = \cdots = v_{n-1} = 0$, then $v_n = \pm 1$ and the lemma obviously holds. So suppose that not all $v_1, v_2, \cdots, v_{n-1}$ are 0. Let $d = \text{g.c.d.}(v_1, \cdots, v_{n-1})$. Then g.c.d. $(d, v_n) = 1$ and so we may find $\alpha, \beta \in \mathbb{Z}$ such that $\alpha v_n + \beta d = 1$. Apply the induction hypotheses to the vector $w = (v_1/d, \cdots, v_{n-1}/d) \in \mathbb{Z}^{n-1}$ and obtain vectors $w^2, \cdots, w^{n-1} \in \mathbb{Z}^{n-1}$ such that w, w^2 , \cdots, w^{n-1} form a basis for \mathbb{Z}^{n-1} . Thus the matrix A with rows w, w^2, \cdots, w^{n-1} is unimodular, and so det $A = \pm 1$. Let B be the matrix with rows $dw, w^2, w^3, \cdots, w^{n-1}$. Then det $B = d(\det A)$ and the first row of B is $dw = (v_1, v_2, \cdots, v_{n-1})$. Set $w^i = (w_1^i, \cdots, w_{n-1}^i)$ for $2 \leq i \leq n-1$. Form the matrix C indicated below.

	v_1	•	•	•	v_{n-1}	v_n
	$w_{\scriptscriptstyle 1}^{\scriptscriptstyle 2}$	•	•	•	w_{n-1}^2	0
	•	•	•	•	•	•
~	•	•	•	•	•	•
C =	•	•	•	•	•	•
	w_1^{n-1}	•	•	•	\mathcal{W}_{n-1}^{n-1}	0
	$rac{ilpha v_{_1}}{d}$	•	•	•	$rac{ilpha v_{n-1}}{d}$	$(\det A)eta$

where $i = -\det A$. Then expanding det C on the last column we find det $C = \alpha v_n + \beta d = 1$. Thus the last n - 1 rows satisfy the lemma.

LEMMA 4. If $v^1, v^2, \dots, v^r \in \mathbb{Z}^n$, $n \ge 1$, then there is a unimodular matrix A with rows A^1, \dots, A^n such that $\operatorname{sp} \{A^1, \dots, A^q\} = \operatorname{sp} \{v^1, \dots, v^r\}$, where $\operatorname{sp} V =$ the linear span in \mathbb{R}^n for $V \subset \mathbb{R}^n$, and $q = \dim \operatorname{sp} \{v^1, \dots, v^r\}$.

Proof. We may suppose v^1, \dots, v^r are linearly independent in \mathbb{R}^n . We will use induction on r. For r = 1, Lemma 3 with $v = d^{-1}v^1$ where $v^1 = (v_1^1, \dots, v_n^1)$ and $d = \text{g.c.d.}(v_1^1, \dots, v_n^1)$ gives the desired conclusion.

Suppose now that $r \ge 2$ and that Lemma 4 holds for r-1. Apply this supposition to v^1, \dots, v^{r-1} and obtain a unimodular matrix *B* such that its rows B^1, \dots, B^n satisfy $\operatorname{sp} \{B^1, \dots, B^{r-1}\} = \operatorname{sp} \{v^1, \dots, v^{r-1}\}$. Note that $\operatorname{sp} \{B^1, \dots, B^{r-1}, v^r\} = \operatorname{sp} \{v^1, \dots, v^{r-1}, v^r\}$.

By considering the linear transformation from \mathbb{R}^n to \mathbb{R}^n whose matrix is B it is easily seen that it is sufficient to prove the lemma in the special case where $B^i = e^i$. Now let $v^r = (\alpha_1, \dots, \alpha_n)$, and set

$$w=(0,\,\cdots,\,0,\,lpha_r,\,lpha_{r+1},\,\cdots,\,lpha_n)=v^r-(lpha_1,\,\cdots,\,lpha_{r-1},\,0,\,\cdots,\,0)\;.$$

Then $\operatorname{sp}\{B^1, \dots, B^{r-1}, v^r\} = \operatorname{sp}\{B^1, \dots, B^{r-1}, w\}$. Since v^r is independent of B^1, \dots, B^{r-1} , not all of $\alpha_r, \alpha_{r+1}, \dots, \alpha_n$ can vanish. Set d =g.c.d. $\{\alpha_r, \alpha_{r+1}, \dots, \alpha_n\}$, and $u = d^{-1}w$. Then $u \in \{0\} \times \mathbb{Z}^{n-r+1}$ and the greatest common divisor of its coordinates is 1. Hence by Lemma 3 there is an $(n - r + 1) \times (n - r + 1)$ unimodular matrix C such that the first row is $\alpha_r/d, \dots, \alpha_n/d$. Set

Then A is unimodular, and its first r rows are B^1, \dots, B^{r-1}, u which have the same span in \mathbb{R}^n as does v^1, \dots, v^r .

Suppose $f: T^n \to T^n$, $n \ge 1$, is a map and A is the matrix of $H_1(f): H_1(T^n) \to H_1(T^n)$. It is shown in [1] that $L(f) = \det(1 - A^t) = \det(1 - A)$, where $A^t =$ the transpose of A = the matrix of $H^1(f)$: $H^1(T^n) \to H^1(T^n)$. Let $\lambda_1, \dots, \lambda_n$ be the characteristic roots of A. Then $L(f) = \prod_{i=1}^n (1 - \lambda_i)$. Since $\lambda_1^m, \dots, \lambda_n^m$ are the characteristic roots of A^m we have proved the following formula.

(*)
$$L(f^m) = \prod_{i=1}^n (1 - \lambda_i^m) .$$

LEMMA 5. Let $\lambda_1, \dots, \lambda_n$ be complex numbers, none of them 1, such that the set $\{\prod_{i=1}^n | 1 - \lambda_i^m | | m = 1, 2, \dots\}$ is bounded, then $|\lambda_i| \leq 1$ for all $i = 1, \dots, n$.

Proof. Suppose not. Divide $\{1, \dots, n\}$ into four sets I, J, K, and L by setting $I = \{i \mid |\lambda_i| > 1\}$, $J = \{i \mid |\lambda_i| < 1\}$, $K = \{i \mid \lambda_i$ is a root of unity}, and $L = \{i \mid |\lambda_i| = 1$ and $\lambda_i^q \neq 1$ for all $q \ge 1\}$. For any $U \subset \{1, \dots, n\}$, set $U_m = \prod_{i \in U} |1 - \lambda_i^m|$, with the convention that if $U = \emptyset$, then $U_m = 1$ for all m. Formula (*) gives $|L(f^m)| = I_m J_m K_m L_m$. Since $I \neq \emptyset$ we clearly have

$$(1) I_m \longrightarrow \infty .$$

Also

$$(2) J_m \longrightarrow \mathbf{1}.$$

For each $i \in K$, let $q_i \ge 1$ be such that $\lambda_i^{q_i} = 1$ and $\lambda_i^m \ne 1$ for $1 \le m < q_i$. If $K \ne \emptyset$, set $q = \prod_{i \in K} q_i$. If $K = \emptyset$, set q = 1. In either case, for $p \ge 0$,

$$(3) K_{qp+1} = K_1 > 0.$$

Here we have used the hypothesis that $\lambda_i \neq 1$ for all *i*.

Set N = # L. From the definition of L we see that $1 \notin \{\lambda_i^{qr} \mid i \in L, r = 1, \dots, N\}$, and hence we can find an $\varepsilon > 0$ such that $|1 - \lambda_i^{qr}| > 2\varepsilon$ for $i \in L$ and $1 \leq r \leq N$.

Claim. For each $i \in L$, and each positive integer a, at most one member of the sequence $\lambda_i^{q,m+1}$, where $a(N+1) < m \leq (a+1)(N+1)$, satisfies

$$|1-\lambda_i^{q_{m+1}}|\leq arepsilon$$
 .

Proof. Suppose not. Then there is an $i \in L$, m and r such that $1 \leq r \leq N$, and $|1 - \lambda_i^{qm+1}| \leq \varepsilon$, and $|1 - \lambda_i^{q(m+r)+1}| \leq \varepsilon$. It follows that

$$egin{aligned} &2arepsilon \geq |\,\lambda_{\iota}^{q(m+r)+1} - \lambda_{i}^{q\,m+1}\,| = |\,\lambda_{i}^{q\,m+1}\,|\,|\,\lambda_{i}^{qr} - 1\,| \ &= |\,\lambda_{i}^{qr} - 1\,| > 2arepsilon$$
 ,

a contradiction. This proves the claim.

Since the number of *m*'s which satisfy $a(N+1) < m \leq (a+1)(N+1)$ is N+1 and N = #L, for each *a* there is an *m* such that $a(N+1) < m \leq (a+1)(N+1)$, and $|1 - \lambda_i^{qm+1}| > \varepsilon$ for all $i \in L$. Hence $L_{mq+1} \geq \varepsilon^N$ for an infinite number of *m*'s. Note that this also holds when N = 0. Combining this with (1), (2), and (3) we see that $|L(f^m)|$ is unbounded, a contradiction. Hence $|\lambda_i| \leq 1$ for all *i*.

LEMMA 6. Given a map $f: T^n \to T^n$, $n \ge 1$, such that 1 is not a characteristic root of $H_1(f): H_1(T^n) \to H_1(T^n)$, and $L(f^m)$, $m = 1, 2, \cdots$, are bounded. Then each nonzero characteristic root of $H_1(f)$ is a root of unity.

Proof. Let $\lambda_1, \dots, \lambda_n$ be the characteristic roots of $H_1(f)$. By Lemma 5 we know that $|\lambda_i| \leq 1$ for all *i*.

Next we will show that for each i, $|\lambda_i| = 0$ or 1. Suppose not. Let $U = \{i \mid \lambda_i \neq 0\}$, and q = #U. Let

$$P(\lambda) = \prod_{i=1}^{n} (\lambda - \lambda_i) = \lambda^n + a_1 \lambda^{n-1} + \cdots + a_n$$

be the characteristic polynomial of $H_1(f)$. Then $a_q = \prod_{i \in U} (-\lambda_i) \neq 0$.

Since a_q is an integer, we have

$$1 \leq |a_q| = \prod_{i \in U} |\lambda_i| < 1$$

because $|\lambda_i| \leq 1$ for all *i*, and $0 < |\lambda_i| < 1$ for some *i*. This contradiction shows that for each *i*, $|\lambda_i| = 0$ or 1.

Note that $a_m = 0$ for m > q, and so

$$P(\lambda) = \lambda^{n-q}(\lambda^q + a_1\lambda^{q-1} + \cdots + a_q) = \lambda^{n-q}Q(\lambda)$$
.

All the roots of $Q(\lambda)$ have unit modulus. It is known, [4] page 122, that if all the roots of a monic polynomial with integer coefficients have unit modulus, then they all are roots of unity. This completes the proof.

4. Geometric lemmas.

LEMMA 7. Suppose the finite group G acts smoothly on a compact manifold M, and that $P = \{x \in M \mid gx = x \text{ for some } g \in G, g \neq 1\}$ is finite. Then there exists a Morse function $\varphi: M \to R$ such that $\varphi \circ g = \varphi$ for all $g \in G$. Furthermore, each $x \in P$ is a critical point of φ .

Proof. Following Milnor [5], we will say that a smooth map $f: M \to R$ is "good" on a set $S \subset M$ if f has no degenerate critical points on S.

We begin by obtaining a first approximation, a smooth map $\Psi: M \to \mathbf{R}$, which is invariant (i.e., $\Psi \circ g = \Psi$ for all $g \in G$) and is good on a neighborhood V of P. Then we perturb Ψ equivariently to the desired Morse function φ .

It is easy to define a smooth map $h: M \to R$ such that each $x \in P$ is a nondegenerate critical point of index zero, i.e., in a local coordinate system about x the first partial derivatives vanish and the matrix of second partial derivatives is positive definite at x. These same conditions also hold for each $h \circ g$, $g \in G$, and consequently $\Psi = \sum_{g \in G} h \circ g$ is a first approximation as desired. Clearly, the set V where Ψ is good, is open, contains P, and satisfies g(V) = V for all $g \in G$.

Note that $gx \neq x$ for all $x \in M - V$ and $g \in G$, $g \neq 1$. Now a rather straightforward equivarient version of the argument used in Milnor [5], Theorem 2.7, to prove the existence of Morse functions serves to show that Ψ can be perturbed to an equivarient Morse function φ . A sketch of this equivarient version follows.

We may find coordinate neighborhoods U_1, \dots, U_r such that

$$M-V \subset igcup_{i=1}^r U_i \ , \qquad P\cap \operatorname{cl}\Bigl(igcup_{i=1}^r U_i\Bigr) = arnothing \ , \ \ ext{and} \ \ \ U_i\cap g(U_i) = arnothing$$

for $1 \leq i \leq r$ and $g \in G$, $g \neq 1$. Then $g'(U_i) \cap g(U_i) = \emptyset$ for $1 \leq i \leq r$ and $g, g' \in G, g \neq g'$. We can also find compact sets $C_i \subset U_i$ such that C_1, \dots, C_r cover M - V. We may alter \mathcal{V} in stages so that at the *i*th stage, the new \mathcal{V} is still equivarient and is good on

$$V \cup \left(igcup_{j=1}^i igcup_{g \in G} g(C_j)
ight).$$

At the *i*th step we simply apply the procedure used in the proof of Theorem 2.7 of [5] to U_i and then alter Ψ on $g(U_i)$, for $g \in G$, $g \neq 1$, so as to preserve the property $\Psi \circ g = g$ for all $g \in G$.

LEMMA 8. Suppose the finite group G acts smoothly on a compact connected m-dimensional manifold $M, m \geq 2$, and that $P = \{x \in M | gx = x \text{ for some } g \in G, g \neq 1\}$ is finite. Given a finite set $S \subset M - P$ and a point $x_0 \in M$ such that $gx_0 = x_0$ for all $g \in G$. Then there exists a smooth embedding $\Psi: D^m \to (M - P) \cup \{x_0\}$ such that $\Psi(0) = x_0, S \subset \Psi(\text{int } D^m), \text{ and } g(\Psi(D^m)) = \Psi(D^m) \text{ for all } g \in G$. Furthermore, for each $g \in G, \Psi^{-1} \circ g \circ \Psi: D^m \to D^m$ is the restriction to D^m of an orthogonal linear map.

Proof. We will use induction on ${}^{*}S$. First suppose $S = \emptyset$. It is an easy matter to embed M into \mathbb{R}^{n} for some n such that for each $g \in G$ the map $x \to gx, x \in M$, is the restriction to M of an orthogonal map $L_{g}: \mathbb{R}^{n} \to \mathbb{R}^{n}$. Just start with a smooth embedding $h: M \to \mathbb{R}^{k}$, for some k. Set $E_{g} = \mathbb{R}^{k}$ for each $g \in G$, and define $e: M \to \prod_{g \in G} E_{g} = \mathbb{R}^{k^{\sharp G}}$ by $e(x) = \prod_{g \in G} h(gx)$, for all $x \in M$. Then the maps $e(x) \to e(gx), x \in M$ are restrictions of maps $L_{g}: \mathbb{R}^{k^{\sharp G}} \to \mathbb{R}^{k^{\sharp G}}$ which simply permute the coordinates of $\mathbb{R}^{k^{\sharp G}}$.

Set $n = k^*G$, and identify M with e(M) via e. Let TM_x be the tangent space of M at x, considered as a subspace of R^n . Let $T = x_0 + TM_{x_0}$ be the geometric tangent space through the point x_0 . Let $N: \mathbb{R}^n \to T$ be the orthogonal projection onto T. Then $L_g(T) \subset T$ for all $g \in G$, and so $L_g \circ N = N \circ L_g$ for all $g \in G$. The restriction of N to a neighborhood of x_0 in M is a diffeomorphism onto a neighborhood of x_0 in T. The desired Ψ is now easily constructed from the restriction of $(N \mid W)^{-1}$ to a ball about x_0 .

Now assume that $\Psi: D^m \to M$ satisfies Lemma 8 as stated. We will show that for any $x \in M - (P \cup S)$, Ψ can be altered so as to satisfy Lemma 8 with S replaced by $S \cup \{x\}$. We will use a connectedness argument. Since dim $M \ge 2$ and $P \cup S$ is finite, the space $M - P \cup S$ is connected. Let $V = \{x \in M - P \cup S \mid \text{Lemma 8 holds} \text{ with } S \text{ replaced by } S \cup \{x\}$.

The set V is clearly open in $M - (P \cup S)$. We will show that $(M - (P \cup S)) - V$ is also open. Let $x \in (M - (P \cup S)) - V$. If $gx \in S$

for some $g \in G$, then Ψ already satisfies $S \cup \{x\} \subset \Psi(\operatorname{int} D^m)$. Hence $gx \notin S$ for all $g \in G$. Since $gx \neq x$ for all $g \in G$, $g \neq 1$, we may find a coordinate neighborhood U of x which is diffeomorphic to an open m-ball and such that $g(U) \subset M - (P \cup S)$, and $g(U) \cap U = \emptyset$ for all $g \in G$, $g \neq 1$. Then $g(U) \cap h(U) = \emptyset$ for g, $h \in G$, $g \neq h$. We claim that $U \subset (M - (P \cup S)) - V$. Suppose not. Then we can find a $y \in U \cap V$. Let $k: M \to M$ be a diffeomorphism which is fixed outside of U and k(y) = x. Define $\overline{k}: M \to M$ by

$$ar{k}(p) = egin{cases} p & ext{if} \ \ p
otin igcup_{g \in G} g(U) \ gkg^{-1}(p) & ext{if} \ \ p \in g(U) \ . \end{cases}$$

Then \overline{k} is a well defined diffeomorphism, and Lemma 8 is satisfied with Ψ replaced by $\overline{k} \circ \Psi$ and S replaced by $S \cup \{x\}$. In fact, for each $g \in G$, $\overline{k} \circ g = g \circ \overline{k}$ and so $(\overline{k} \circ \Psi)^{-1} \circ g \circ (\overline{k} \circ \Psi) = \Psi^{-1} \circ g \circ \Psi$. This proves the claim, and hence $(M - (P \cup S)) - V$ is open.

Since $V \neq \emptyset$, we have $V = M - (P \cup S)$, and the induction step is complete.

5. Proofs of the theorems.

Proof of Theorem 4. First recall that a flow on M is a smooth map $F: M \times R \to M$ such that with the notation $F_t(x) = F(x, t)$ we have $F_s \circ F_t = F_{s+t}$ for all $s, t \in R$, and $F_0 = 1_M$. An orbit of F is a function of the form $F^x: R \to M$ where $x \in M$ and $F^x(t) = F(x, t)$ for all $t \in R$. An orbit F^x is periodic if $F^x(s) = F^x(0)$ for some $s \neq 0$. Thus the constant orbits are considered to be periodic.

The idea of the proof is to obtain a flow $H_t: M \to M$ such that the orbits H^x for $x \in P$ are constants and these are the only periodic orbits, and $H_t \circ f = f \circ H_t$. Then $g = H_1 \circ f$ will satisfy the conclusions of the theorem. The desired flow H_t is obtained in several steps.

Since $f^N = 1$, we have a smooth action of $\mathbb{Z}/n\mathbb{Z}$ on M. Let $\varphi: M \to \mathbb{R}$ be the Morse function given by Lemma 7. It is easy to obtain an equivarient Riemannian metric on M. Just average over $\mathbb{Z}/n\mathbb{Z}$ any Riemannian metric. Then the gradient of φ with respect to this equivarient Riemannian metric is an equivarient vector field v. The vector field v determines a flow F on M which satisfies $F_i(f(x)) = f(F_i(x))$ for all $(x, t) \in M \times \mathbb{R}$. The flow also satisfies $\varphi(F_i(x)) > \varphi(x)$ whenever x is not a critical point of φ and t > 0. Hence the only periodic orbits of F are the constant orbits at critical points of φ .

Let $S = \{x \in M \mid x \text{ is a critical point of } \varphi\} - P$. Let $\Psi: D^m \to M$ be given by Lemma 8. Pick $r \in (0, 1)$ such that $S \subset \Psi(D_r^m)$, where $D_r^m = \{x \in \mathbf{R}^m \mid ||x|| \leq r\}$. Let $b: \mathbf{R} \to \mathbf{R}$ be a smooth map satisfying b(t) = 0 for $t \leq r$, b(t) > 0 for t > r, and b(t) = 1 for $t \geq (1 + r)/2$. Define $\overline{b}: M \to R$ by

$$ar{b}(x) = egin{cases} 1 & ext{if } x
otin \mathcal{V}(D^m_{(r+1)/2}) \ b(|| \ \mathcal{V}^{-1}(x) \ ||) & ext{if } x
otin \mathcal{V}(D^m) \ . \end{cases}$$

It is clear that \overline{b} is well defined and smooth. Define a new vector field w by $w(x) = \overline{b}(x)v(x)$. Then w is equivarient under f and determines an equivarient flow G_t . The orbits of G, which are just the integral curves of w, are reparameterizations of portions of orbits of F. The orbits G^x for $x \in \Psi(D_r^m) \cup P$ are constant. All the other orbits are reparameterizations of portions of nonperiodic orbits of F by reparameterization functions which are strictly monotone increasing functions. Hence the orbits G^x for $x \in \Psi(D_r^m) \cup P$ are the only periodic orbits. Let θ : $\mathbf{R} \to \mathbf{R}$ be a smooth map satisfying $\theta(t) = r + t$ for $t \leq 1/3 (1 - r), \theta'(t) > 0$ for all t, and $\theta(t) = t$ for $t \geq r + 2/3 (1 - r)$. We will use later the obvious fact that θ^{-1} : $\mathbf{R} \to \mathbf{R}$ exists and is smooth. Define $h: M - \{x_0\} \to M - \Psi(D_r^m)$ by

$$h(x) = egin{cases} x & ext{if } x
otin arPsi (D^m) \ rac{ heta(||\,x\,||)x}{||\,x\,||} & ext{if } x
otin arPsi (D^m) ext{,} \end{cases}$$

where we have identified $\Psi(D^m)$ with D^m via Ψ . Define $H_t(x)$ by

$$H_t(x)=egin{cases} h^{-1}(G_t(h(x))) & ext{ for } x
eq x_0 \ x_0 & ext{ for } x=x_0 \ . \end{cases}$$

We wish to show that $H_t(x)$ is a smooth flow by showing that $H_t(x)$ is determined by a smooth vector field. Since $H_s \circ H_t = H_{s+t}$, and $H_0 = 1_M$, it is sufficient to show that $\eta(x) = d/dt H_t(x)$ at t = 0 is a smooth vector field. It is clear that $\eta(x)$ is well defined for all $x \in M$ and $\overline{\eta} = \eta \mid M - \{x_0\}$ is smooth. Since $\eta(x_0) = 0$, it is sufficient to show that $\eta(x)$ and all its derivatives approach 0 as $x \to x_0$. We calculate for $x \neq x_0$

$$egin{aligned} \eta(x) &= rac{d}{dt}(H_t(x)) \mid_{t=0} = dh^{-1} \mid_{G_0(h(x))} rac{d}{dt}(G_t(h(x))) \mid_{t=0} \ &= dh^{-1} \mid_{h(x)} w(h(x)) \;. \end{aligned}$$

Since w and all its derivatives vanish on D_r^m , Taylor expansions show that for each derivative a(x) of a component of w(x) and each $n \ge 1$ there is a constant c such that

$$(5) |a(x)| \le c |||x|| - r|^n for x \in \Psi(D^m).$$

The form of h(x) for $x \in \mathcal{V}(D^m) - \{x_0\}$ and $||x|| \leq (1-r)/3$, is

$$h(x) = rac{(r + ||x||)x}{||x||}$$

and hence if u(x) is a derivative of a component of h of order n, then there is a constant e such that

(6)
$$|u(x)| \leq e ||x||^{-n-1}$$
 for $0 < ||x|| \leq \frac{1-r}{3}$.

The map $h^{-1} | (\Psi(D^m) - \Psi(D_r^m))$ has a smooth extention $\overline{h}^{-1}: \varphi(D^m) - \{x_0\} \to \varphi(D^m)$ given by $\overline{h}^{-1}(y) = \theta^{-1}(||y||)y/||y||$. Consequently $dh^{-1}|_y$ and all its derivatives are bounded. Using this and (5) and (6) we see that $\eta(x) = dh^{-1}|_{h(x)} w(h(x))$ and all its derivatives approach 0 as $x \to x_0$. Hence $\eta(x)$ is smooth and therefore so is $H_t(x)$.

It is clear from the definition of $H_t(x)$ and the properties of $G_t(x)$ that the only periodic orbits of H are the constant orbits H^{π} for $x \in P$. It is also clear from the fact that $x \to \Psi^{-1}(f(\Psi(x)))$ is the restriction of a orthogonal linear map to D^m , that $f \circ h = h \circ f$ and hence $f \circ H_t = H_t \circ f$ for all t. The map $(x, t) \to H_t(f(x))$ is a homotopy from $H_0 \circ f = f$ to the smooth map $g = H_1 \circ f$. It is easy to see that the set of periodic points of $H_1 \circ f$ is P and that $H_1 \circ f | P = f | P$. This completes the proof.

LEMMA 9. Suppose there is given a map $g: T^k \to T^k$, $k \ge 2$, which is covered by a linear map $A: \mathbb{R}^k \to \mathbb{R}^k$, and an integer $N \ge 2$, such that $g^N = \mathbf{1}_{T^k}$, and $\lambda^m \ne 1$ for λ a characteristic root of A and $1 \le m < N$. Then there exists a smooth map \overline{g} homotopic to g such that $P = \{x \in T^k \mid g^m(x) = x \text{ for some } m, 1 \le m < N\} = \text{the set of all periodic}$ points of $\overline{g}, \overline{g} \mid P = g \mid P$, and for $m \ge 1 \ \#\{x \in T^k \mid \overline{g}^m(x) = x\} \le a_m(g)$.

Proof. We wish to apply Theorem 4. If follows from Lemma 2 that $P = \{x \in T^k | g^r(x) = x \text{ for some } r, 1 \leq r < N\}$ is finite. Since $N \geq 2, \lambda_i^1 \neq 1$ for all characteristic roots λ_i and hence

$$L(g) = \prod_{i=1}^n \left(1 - \lambda_i\right)
eq 0$$

by formula (*). Hence, we can find an $x_0 \in T^k$ such that $g(x_0) = x_0$. Therefore Theorem 4 gives a smooth map \overline{g} homotopic to g such that P = the set of periodic points of \overline{g} , and $\overline{g} | P = g | P$. It follows from Lemma 2 applied to g, and formula (*), that for $1 \leq m < N$,

$$\#\{x\in T^k\mid ar{g}^{\,m}(x)\,=\,x\}\,=\,\#\{x\in T^k\mid g^{\,m}(x)\,=\,x\}\,=\,\mid L(g^{\,m})\mid\,=\,a_{\,m}(g)$$
 .

$$\begin{split} \# \{x \in T^k \mid \overline{g}^N(x) = x\} \\ &= \sum_{\substack{m < N \\ m \mid N}} \# \{x \in T^k \mid x \text{ is a periodic point of } \overline{g} \text{ of period } m\} \\ &\leq \sum_{\substack{m \mid N \\ m \mid N}} \mid L(g^m) \mid \\ &= \sum_{\substack{m \mid N \\ m \mid N}} \left| \prod_{i=1}^k (1 - \lambda_i^m) \right| \\ &\leq \prod_{i=1}^k \sum_{\substack{m \mid N \\ i = 1}} |1 - \lambda_i^m| \\ &\leq \prod_{i=1}^k a_{iN} \\ &= a_N(g) . \end{split}$$

To complete the proof it is sufficient to show that if $m \ge 1$, $q \ge 1$, and $m \equiv q \mod N$, then

$$\{x\in T^{\,k}\mid ar{g}^{\,m}(x)\,=\,x\}\,=\,\{x\in T^{\,k}\mid ar{g}^{\,q}(x)\,=\,x\}$$
 .

We may assume m < q and so q = m + pN for some $p \ge 1$. Assume $\bar{g}^m(x) = x$. Then $x \in P$ and so $\bar{g}^N(x) = g^N(x) = x$. Consequently $\bar{g}^q(x) = \bar{g}^{m+pN}(x) = \bar{g}^m(x) = x$. The reverse implication, " $\bar{g}^q(x) = x$ implies $\bar{g}^m(x) = x$ " follows similarly. This completes the proof.

REMARK. In our application of Lemma 9 in the proof of Theorem 3, Lemma 9 needs to be augmented by the following observation. Lemma 9 also holds when k = 1 and $N \ge 1$. We verify this as follows. It is easy to deduce that $A = \mathbf{1}_{R^1}$ or $A = -\mathbf{1}_{R^1}$. In the first case, $A = \mathbf{1}_{R^1}$, we can homotopy $g = \mathbf{1}_{T^1}$ to a rotation \overline{g} of the circle $S^1 = T^1$ by an angle which has an irrational ratio to 2π . Such a \overline{g} has no periodic points and Lemma 9 is verified in this case.

In the second case, $A = -1_{R^1}$, g is a reflection and there are exactly two fixed points x_0 and x_1 . It is easy to homotopy g to a map \overline{g} which leaves x_0 and x_1 fixed, and moves all other points away from x_0 and closer to x_1 . Then x_0 and x_1 will be the only periodic points of \overline{g} . It is easy to calculate that $a_m(g) = 2$ for all $m \ge 1$, and so Lemma 9 holds in this case also.

Proof of Theorem 3. We prove Theorem 3 by induction on n. By convention \mathbb{R}^0 and T^0 are singletons. Hence the case n = 0 holds trivially. Now assume that n > 0 and the theorem holds for all m < n. Let $f: T^n \to T^n$ be a map.

By Lemma 1 we may assume that f is covered by a linear map $F: \mathbb{R}^n \to \mathbb{R}^n$. By Lemma 5 we have

$$L(f^{m})=\prod\limits_{j=1}^{n}\left(1-\lambda_{i}^{m}
ight)$$

where $\lambda_1, \dots, \lambda_n$ are the characteristic roots of F.

First consider the case where $\lambda_i^m \neq 1$ for all $m \ge 1$ and $1 \le i \le n$. Then the theorem follows from Lemmas 2 and 5.

Consider now the remaining case where $\lambda_i^m = 1$ for some $m \ge 1$ and $1 \le i \le n$. Let N be the smallest such m. Let \overline{F}^t denote the transpose of \overline{F} . Since $(\overline{F}^t)^N$ has integer entries, we may find a $w \in \mathbb{Z}^n$ such that $w \ne 0$ and $(\overline{F}^t)^N w = w$. Set

$$W = \operatorname{sp}_{R^n} \{ (ar{F}^t)^m w \mid 0 \leq m < N \}$$
.

Then dim $W \ge 1$, $\overline{F}^{i}u \in W$ for all $u \in W$, and $(\overline{F}^{i})^{N}x = x$ for all $x \in W$. Set $k = \dim W$. By Lemma 4, we can find a basis $w^{1}, w^{2}, \dots, w^{n}$ for \mathbb{Z}^{n} such that $w^{1}, w^{2}, \dots, w^{k}$ form a basis for W. Let $K: \mathbb{R}^{n} \to \mathbb{R}^{n}$ be the linear transformation whose matrix satisfies $\overline{K}^{i}e^{i} = w^{i}$. Then, both \overline{K} and \overline{K}^{-1} have integer entries. Thus, both K and K^{-1} induce maps $K': T^{n} \to T^{n}$, and $K^{-1'} = K'^{-1}: T^{n} \to T^{n}$. We "change coordinates" by noting that it is sufficient to prove the theorem for

$$g = K' \circ f \circ K'^{-1}$$

in place of f. The map g is covered by

$$M = K \circ F \circ K^{-1} \colon \mathbf{R}^n \longrightarrow \mathbf{R}^n$$
 .

From $\bar{K}^t e^i = w^i$ and $\bar{F}^t u \in W$ for $u \in W$, it follows that the matrix \bar{M} of M has the form

$$ar{M} = \left(egin{array}{c|c} ar{A} & 0 \ \hline ar{C} & ar{B} \end{array}
ight)$$

where $\bar{A}, \bar{B}, \bar{C}$, and 0 are $k \times k$, $(n-k) \times (n-k)$, $(n-k) \times k$ and $n \times (n-k)$ matrices, and all entries of 0 are zero. It follows from $\bar{F}^{t^N}x = x$ for all $x \in W$, that $\bar{A}^N = 1$. Since $\bar{M} = \bar{K} \cdot \bar{F} \cdot \bar{K}^{-1}$ is similar to $\bar{F}, \lambda_1, \dots, \lambda_n$ are the characteristic roots of \bar{M} . Hence, we may renumber the λ_i 's so that $\lambda_1, \dots, \lambda_k$ and $\lambda_{k+1}, \dots, \lambda_n$ are the characteristic roots of \bar{A} and \bar{B} respectively. Let

$$B: \mathbf{R}^{n-k} \longrightarrow \mathbf{R}^{n-k}$$

be the linear map whose matrix is \overline{B} . Then B induces a map $b: T^{n-k} \to T^{n-k}$. Since $k = \dim W \ge 1$, we may apply our induction hypothesis to b and find a smooth map \overline{b} homotopic to b such that

$$\# \{x \in T^{n-k} \mid \overline{b}^{m}(x) = x\} \leq a_{m}(b) = \prod_{i=k+1}^{n} a_{im} .$$

Let $A: \mathbb{R}^k \to \mathbb{R}^k$ be the linear map whose matrix is \overline{A} . Let $a: T^k \to T^k$ be the map induced by A. Since $\overline{A}^N = 1$, we have $a^N = \mathbf{1}_{T^k}$. Because we choose N so that $\lambda_i^m \neq 1$ for $1 \leq m < N$ and all i, and N = 1 implies k = 1, we see that Lemma 9 or the remark which follows it applies. Hence we can find a smooth map \overline{a} homotopic to a such that $P = \{x \in T^k \mid a^m(x) = x \text{ for some } m, 1 \leq m < N\}$ = the set of all periodic points of $\overline{a}, \overline{a} \mid P = a \mid P$, and for $m \geq 1$,

$$\# \{x \in T^k \mid \overline{a}^m(x) = x\} \leq a_m(a) = \prod_{i=1}^k a_{im}$$
.

If we write $\mathbf{R}^n = \mathbf{R}^k \times \mathbf{R}^{n-k}$, then M has the form

$$M(x, y) = (\overline{A}x, \overline{C}x + \overline{B}y)$$
.

Consequently, if we write $T^n = T^k \times T^{n-k}$, then g(u, v) = (a(u), r(u, v))where $r: T^k \times T^{n-k} \to T^k$ is the map induced by the map $R: \mathbb{R}^k \times \mathbb{R}^{n-k} \to \mathbb{R}^k$ which is given by $R(x, y) = \overline{C}x + \overline{B}y$. The homotopy from a to \overline{a} gives rise to a homotopy from g to \overline{g} where

$$\overline{g}(u, v) = (\overline{a}(u), r(u, v))$$
.

The periodic points of \overline{g} must have the form

$$(u, v) \in T^k \times T^{n-k}$$
 where $u \in P$.

Partition P into orbits under \bar{a} . Let

$$X = \{u_i = \bar{a}^i(u_0) \mid i = 0, 1, \dots, m-1\}$$

be one such orbit consising of m distinct point, where $1 \leq m < N$ and $\bar{a}^m(u_0) = u_0$. Consider the maps

which are covered by the maps

$$M_i = M \,|\, x_i imes oldsymbol{R}^{n-k}$$
: $x_i imes oldsymbol{R}^{n-k}$ \longrightarrow $x_{i+1} imes oldsymbol{R}^{n-k}$

where $u_m = \bar{a}^m(u_0) = u_0$ and x_0 is chosen so that $\pi(x_0) = u_0$, and $x_i = \bar{A}^i x_0$ for $i \ge 1$, (recall that $\bar{a} \mid P = a \mid P$). Making the obvious identifications of $u_i \times T^{n-k}$ with T^{n-k} , and $x_i \times R^{n-k}$ with R^{n-k} we see that

$$M_i(y)=ar{C}x_i+ar{B}y$$

for all $y \in \mathbf{R}^{n-k}$. Define

$$M_{ii}(y) = t ar{C} x_i + ar{B} y$$
 .

Then $M_{i1} = M_i$ and M_{i0} has \overline{B} as its matrix. Because \overline{B} has integer entries and $t\overline{C}x_i$ does not depend on y, the homotopy M_{ii} induces a

homotopy g_{ii} from $g_{i1} = g_i$ to the map induced by M_{i0} , which is b. Since b is homotopic to \overline{b} , each g_i is homotopic to \overline{b} . Since both g_i and \overline{b} are smooth, we may find a smooth homotopy $h_i: T^{n-k} \times I \to T^{n-k}$ such that for some $\varepsilon > 0$, $h_i(v, t) = \overline{b}(v)$ for all $t < \varepsilon$, and $h_i(v, t) = g_i(v) = r(u_i, v)$ for all $t > 1 - \varepsilon$.

Pick coordinate charts (U_i, φ_i) about the points u_i such that $\{u_i\} = U_i \cap P, \varphi_i(U_i) = B_1(0) \subset \mathbb{R}^k$, and $\varphi_i(u_i) = 0$. Using the natural group structure on T^{n-k} we define

$$r_t: T^k \times T^{n-k} \longrightarrow T^{n-k} \quad \text{for } t \in [0, 1]$$

by

$$r_i(u,\,v) = egin{cases} r(u,\,v) + h_i(v,\,t\,||\,arphi_i(u)\,|| + 1 - t) - r(u_i,\,v) & ext{ if } u \in U_i \ r(u,\,v) & ext{ if } u \notin igcup_{i=1}^m U_i \ . \end{cases}$$

Using r_t we obtain a homotopy

$$\overline{g}_t(u, v) = (\overline{a}(u), r_t(u, v))$$

from $\overline{g}_0 = \overline{g}$ to \overline{g}_1 , where $\overline{g}_1(u, v) = (\overline{a}(u), r_1(u, v))$. Note that $r_1(u_i, v) = \overline{b}(v)$ for each $i = 0, 1, \dots, m-1$. Proceed similarly with the other orbits in P and call the final map \widetilde{g} .

The map \tilde{g} will be smooth and homotopic \bar{g} and hence homotopic to g. For all $(u, v) \in T^k \times T^{n-k}$, $\tilde{g}(u, v) \in (\bar{a}(u), \tilde{r}(u, v))$ for some map $\tilde{r}: T^k \times T^{n-k} \to T^{n-k}$ which satisfies $\tilde{r}(u, v) = \bar{b}(v)$ for all $u \in P$.

Now suppose $\tilde{g}^m(u, v) = (u, v)$. Then $\bar{a}^m(u) = u$ and so $u \in P$. Hence $\bar{a}^i(u) \in P$ for all *i* and so by an easy induction $\tilde{g}^i(u, v) = (\bar{a}^i(u), \bar{b}^i(v))$. Applying this with i = m we see that $\bar{b}^m(v) = v$. Hence

$$egin{aligned} & \#\{(u,\,v)\in T^k imes T^{n-k}\mid \widetilde{g}^{\,m}(u,\,v)=(u,\,v)\}\ &\leq \#\{u\in T^k\mid ar{a}^{\,m}(u)=u\} imes \#\{v\in T^{n-k}\mid b^{m}(v)=v\}\ &\leq \prod_{i=1}^k a_{im}\cdot\prod_{i=k+1}^n a_{im}=a_m\ . \end{aligned}$$

This completes the proof.

Proof of Theorem 1. The "if" direction follows from the Nielsen fixed point theorem and Theorem 2.

Next we prove the converse direction. Assume that $L(f^m)$, $m = 1, 2, \cdots$, are bounded. We may assume $n \ge 1$. Let g be the map given by Theorem 3. If 1 is a characteristic root of $H_1(f): H_1(T^n) \to H_1(T^n)$, then g has no periodic points because $a_m(f) = 0$ for all $m \ge 1$. So assume that 1 is not a characteristic root of $H_1(f)$. Now from Lemma 6 we have $|\lambda_i| \le 1$ for all i, where $\lambda_1, \cdots, \lambda_n$ are the characteristic roots of $H_1(f)$. Consequently, there exists a B such that

 $a_{im} \leq B$ for all $i = 1, \dots, n$, and $m \geq 1$. Thus $a_m(f) \leq B^n$ for all $m \geq 1$.

We will show that the number of periodic points of g is bounded by B^n . Suppose on the contrary that $S = \{x_i \mid 1 \leq i \leq B^n + 1\}$ is a set of $B^n + 1$ distinct periodic points such that x_i has period m_i . Set

$$m=\prod_{i=1}^{B^{n+1}}m_i$$
 .

Then $S \subset \{x \in T^n \mid g^m(x) = x\}$. But, by Theorem 3,

$$\# \{x \in T^{\,n} \mid g^{\,m}(x) = x\} \leqq a_{\,m}(f) \leqq B^{n}$$
 ,

a contradiction. This completes the proof.
