## **ON THE HANDLEBODY DECOMPOSITION ASSOCIATED TO A LEFSCHETZ FIBRATION**

ARNOLD SAMUEL KAS

# ON THE HANDLEBODY DECOMPOSITION ASSOCIATED TO A LEFSCHETZ FIBRATION

A. KAS

The classical Lefschetz hyperplane theorem in algebraic geometry describes the homology of a projective algebraic manifold  $M$  in terms of "simpler" data, namely the homology of a hyperplane section  $X$  of  $M$  and the vanishing cycles of a Lefschetz pencil containing  $X$ . This paper is a first step in proving a diffeomorphism version of the Lefschetz hyperplane theorem, namely a description of the diffeomorphism type of  $M$  in terms of "simpler" data.

Let  $\tilde{M}$  be the manifold obtained from  $M$  by blowing up the axis of a Lefschetz pencil. There is a holomorphic mapping  $f: \tilde{M} \rightarrow \mathbb{CP}^1$  which is a Lefschetz fibration, i.e.,  $f$  has only nondegenerate critical points (in the complex sense). Using the Morse function  $z \rightarrow |f(z)|^2$  on  $\tilde{M} - f^{-1}(\infty)$ , one obtains a handlebody decomposition of  $\tilde{M} - f^{-1}(\infty)$  which may be described as follows: Let  $X = f^{-1}(a)$  be a regular fiber of  $f$ . Choose a system of smooth arcs  $\gamma_1, \dots, \gamma_\mu$  starting at  $a$  and ending at the critical values of  $f$  such that the  $\gamma$ 's are pairwise disjoint except for their common initial point. The  $\gamma$ 's are ordered such that the tangent vectors  $\gamma'_1(0), \dots, \gamma'_\mu(0)$  rotate in a counter clockwise manner. To each  $\gamma_j$  one may associate a "vanishing cycle", i.e., an imbedding  $\phi_j: S^n \rightarrow X$  ( $\dim X = 2n$ ) defined up to isotopy, together with a bundle isomorphism  $\phi'_j: \tau \rightarrow \nu$  where  $\tau$  is the tangent bundle to  $S^n$  and  $\nu$  is the normal bundle of  $S^n$  in  $X$  corresponding to the imbedding  $\phi_j$ .  $\phi'_j$  together with the well known bundle isomorphism  $\tau \oplus \varepsilon \simeq \varepsilon^{n+1}$  determines a trivialization of the normal bundle of  $e^{2\pi i j/\mu} \times \phi_j(S^n)$  in  $S^1 \times X$ . This trivialization allows one to attach a  $n$ -handle to  $D^2 \times X$  with the core  $e^{2\pi i j/\mu} \times \phi_j(S^n)$ . If this is done for each  $j, j=1, \dots, \mu$ , the resulting manifold is diffeomorphic to  $\tilde{M}$ -(tubular neighborhood of  $f^{-1}(\infty)$ ).

Using the bundle isomorphism  $\phi'_j$  and the tubular neighborhood theorem one may identify a closed tubular neighborhood  $T$  of  $\phi_j(S^n)$  in  $X$  with the tangent unit disk bundle to  $S^n$ . One may then define a diffeomorphism, up to isotopy,  $\delta_j: X \rightarrow X$  with support in  $T$ .  $\delta_j$  is a generalization of the classical Dehn-Lickorish twist.  $\delta_j$  is the geometric monodromy corresponding to the  $j$ th critical value of  $f$ . It follows that the composition  $\delta_\mu \circ \dots \circ \delta_1$  is smoothly isotopic to the identity  $1_X: X \rightarrow X$ . A smooth isotopy is given by a smooth arc  $\lambda$  in  $\text{Diff}(X)$  joining the identity to  $\delta_\mu \circ \dots \circ \delta_1$ . The choice of  $\lambda$ , up to homotopy, determines the way in which one closes off  $\tilde{M}$ -(tubular neighborhood of  $f^{-1}(\infty)$ ) to obtain  $\tilde{M}$ .

Thus the diffeomorphism type of  $\tilde{M}$  is determined by the invariants  $\phi_1, \phi'_1, \dots, \phi_\mu, \phi'_\mu$  and  $\{\lambda\}$ , the homotopy class of  $\lambda$ . Conversely, given a compact oriented  $2n$  dimensional manifold  $X$ , imbeddings  $\phi_j: S^n \rightarrow X$ ,  $j=1, \dots, \mu$ , and bundle isomorphisms  $\phi'_j: \tau \sim \nu_j$  such that  $\delta_\mu \circ \dots \circ \delta_1$  is smoothly isotopic to  $1_X$ , and a homotopy class  $\{\lambda\}$  of arcs in  $\text{Diff}(X)$  with initial point  $1_X$  and end point  $\delta_\mu \circ \dots \circ \delta_1$ , one may construct a  $2n+2$  dimensional manifold  $\tilde{M}$  and a Lefschetz fibration  $f: \tilde{M} \rightarrow \mathbb{CP}^1$ . It is shown that in the case  $n=1$ , apart from certain exceptions,  $\tilde{M}$  is uniquely determined by  $\phi_1, \dots, \phi_\mu$ , i.e., the bundle isomorphisms  $\phi'_1, \dots, \phi'_\mu$  and the smooth isotopy class  $\{\lambda\}$  are superfluous.

**O. Introduction.** The classical Lefschetz hyperplane theorem in algebraic geometry describes the homology groups of an algebraic manifold  $M$  in terms of those of a hyperplane section  $X$  and in terms of the "vanishing cycles" of  $X$ . This paper was inspired by the Morse theoretic proof of the Lefschetz hyperplane theorem due to Andreotti and Frankel [1]. Their approach is to blow up the base locus of a generic Lefschetz pencil so as to obtain a manifold  $\tilde{M}$  and a "Lefschetz fibration"  $f: \tilde{M} \rightarrow P^1(C)$ . They then use the Morse function  $|f|^2$  to describe  $\tilde{M}$ , at least up to homotopy type, and finally they show how to relate the homology groups of  $M$  to those of  $\tilde{M}$ . Now according to Smale's handlebody theory [11], it should be possible to use the Morse function  $|f|^2$  to determine the full diffeomorphism class of  $\tilde{M}$ , not just its homotopy type. In order to do this we must describe the framings of the imbedded spheres (vanishing cycles) corresponding to the critical points of  $|f|^2$ . In general, the framing associated to a critical point of index  $n+1$ , has an ambiguity measured by  $\pi_n(SO(n+1))$ . In our situation, we can improve this to  $\pi_n(SO(n))$ . This completely determines the framing in certain cases, most notably if  $M$  is a complex surface.

In this paper, we describe a set of invariants associated to a Lefschetz fibration  $f: M \rightarrow P^1$ , which allows one, in principle, to give a handlebody decompositions of certain complex surfaces.

There is a certain amount of overlap between some of the ideas of this paper and certain papers of B. Moishezon and R. Mandelbaum (cf. e.g., [6], [7], [10]).

**1. The framings associated with a Lefschetz fibration.** Let  $M$  be a smooth manifold of dimension  $\geq 2$  and let  $f: M \rightarrow S^2$  be a smooth mapping. A point  $p \in M$  will be called a critical point of  $f$  if the differential  $df_p: T(M)_p \rightarrow T(S^2)_{f(p)}$  is not surjective. Now let  $M$  be a closed compact oriented smooth manifold of even dimension,

say  $\dim M = 2n + 2$ ,  $n \geq 0$ , and assume that  $f: M \rightarrow S^2$  is a surjective mapping with a finite number of critical points. We will identify  $S^2$  with the extended complex plane  $C \cup \infty$ . If  $z \in S^2$  is a regular value of  $f$ , then  $f^{-1}(z)$  is called a regular fiber of  $f$ . It is clear that up to diffeomorphism, the regular fibers of  $f$  are independent of the regular value  $z$ .

DEFINITION 1.1. The smooth mapping  $f: M \rightarrow S^2$  will be called a Lefschetz fibration if each critical point  $p$  of  $f$  admits a coordinate neighborhood with complex valued coordinates  $(w_1, \dots, w_{n+1})$ , consistent with the given orientation of  $M$ , and if  $f(p)$  has a coordinate neighborhood with a complex coordinate  $z$ , consistent with the orientation of  $S^2$ , such that locally,  $f$  has the form:

$$f(w) = z_0 + w_1^2 + \dots + w_{n+1}^2.$$

DEFINITION 1.2. Two Lefschetz fibrations

$$f_1: M \longrightarrow S^2, \quad \text{and} \quad f_2: M \longrightarrow S^2$$

are said to be equivalent, if  $f_2 = g \circ f_1$  where  $g$  is an orientation preserving diffeomorphism of  $S^2$ .

Let  $X$  denote any regular fiber of the Lefschetz fibration  $f: M \rightarrow S^2$ . Notice that up to diffeomorphism,  $X$  only depends on the equivalence class of the Lefschetz fibration  $f: M \rightarrow S^2$ . Notice also, that  $X$  has a unique orientation consistent with the orientations of  $M$  and  $S^2$ .

We wish to describe a handlebody decomposition of  $M$  associated to the Lefschetz fibration  $f: M \rightarrow S^2$ . We will assume that a handlebody decomposition of  $X$  is already known.

We first recall some standard facts about handles and handlebodies. Let  $N$  be a manifold with boundary and let  $n = \dim N$ . Let

$$\Phi: S^{k-1} \times D^{n-k} \longrightarrow \partial N$$

be a smooth imbedding. Form the union  $N_1 = N \cup_{\Phi} D^k \times D^{n-k}$  where we identify each point of  $S^{k-1} \times D^{n-k} \subset \partial(D^k \times D^{n-k})$  with its image under  $\Phi$ .  $N_1$  is a manifold with boundary and corner points. Let  $V$  denote the unique manifold (possibly with boundary) obtained from  $N_1$  by "straightening the corners" of  $N_1$  (cf. [2]).

DEFINITION 1.3.  $V$  is called: the manifold obtained from  $N$  by attaching a  $k$ -handle along  $\Phi$ .

It is easy to see that, up to diffeomorphism,  $V$  depends only on the smooth isotopy class of  $\Phi$ . Let  $\Phi_0$  denote the restriction of

$\Phi$  to  $S^{k-1} \times 0$ . It follows easily from the tubular neighborhood theorem [9], that  $\Phi$  is determined, up to smooth isotopy, by a bundle isomorphism:

$$\Phi': \varepsilon^{n-k} \longrightarrow \nu$$

where  $\varepsilon^{n-k}$  is the trivial  $n - k$  bundle on  $S^{k-1}$ , and  $\nu$  is the normal bundle of  $S^{k-1}$  in  $\partial N$  under the imbedding  $\Phi_0$ . Thus the isotopy class of the imbedding  $\Phi$  is determined by:

(i) A smooth isotopy class of imbeddings

$$\Phi_0: S^{k-1} \longrightarrow \partial N;$$

(ii) For each  $\Phi_0$  in (i), a smooth isotopy class of bundle isomorphisms:

$$\Phi': \varepsilon^{n-k} \longrightarrow \nu.$$

Notice that (i) is a "knot invariant". As for (ii), the distinct bundle isomorphisms, up to smooth isotopy, are classified by the group  $\pi_{k-1}(SO(n - k))$ .  $\Phi'$  is called a framing of  $\Phi_0$ .

Let  $F: M \rightarrow \mathbf{R}$  be a Morse function, and let  $c \in \mathbf{R}$  be a critical value such that  $F^{-1}(c)$  contains a single critical point  $p$ , where  $F$  has index  $\lambda$  at  $p$ . For each real number  $a \in \mathbf{R}$ , let  $M_a = \{x \in M | F(x) \leq a\}$ . Then for  $\varepsilon > 0$  sufficiently small,  $M_{c+\varepsilon}$  is diffeomorphic to the manifold obtained from  $M_{c-\varepsilon}$  by attaching a  $\lambda$ -handle along  $\Phi: S^{\lambda-1} \times D^{n-\lambda} \rightarrow \partial M_{c-\varepsilon}$ . To construct  $\Phi$  explicitly, one may choose (by Morse's lemma) a system of coordinates  $x_1, \dots, x_n$  in  $M$  centered at  $p$ , such that  $F(x_1, \dots, x_n) = c - x_1^2 - \dots - x_\lambda^2 + x_{\lambda+1}^2 + \dots + x_n^2$  (cf. e.g., [8]). Then if  $\xi = (\xi_1, \dots, \xi_\lambda) \in S^{\lambda-1}$ ,  $\eta = (\eta_{\lambda+1}, \dots, \eta_n) \in D^{n-\lambda}$ ,  $\Phi: S^{\lambda-1} \times D^{n-\lambda} \rightarrow F^{-1}(c - \varepsilon)$  is defined by setting

$$\Phi(\xi, \eta) = (x_1, \dots, x_n)$$

where

$$\begin{aligned} (x_1, \dots, x_\lambda) &= \sqrt{\varepsilon + |\eta|^2} \xi \\ (x_{\lambda+1}, \dots, x_n) &= \eta. \end{aligned}$$

Similarly, if  $F^{-1}(c)$  contains several nondegenerate critical points  $p_1, \dots, p_\mu$  of indices  $\lambda_1, \dots, \lambda_\mu$ , then  $M_{c+\varepsilon}$  is diffeomorphic to the manifold obtained from  $M_{c-\varepsilon}$  by attaching  $\mu$  handles, where the  $j$ th handle is a  $\lambda_j$ -handle attached along  $\Phi_j: S^{\lambda_j-1} \times D^{n-\lambda_j} \rightarrow F^{-1}(c - \varepsilon)$ ,  $j = 1, \dots, \mu$ , and where the images of the  $\Phi_j$  are disjoint.

**DEFINITION 1.4.** A handlebody decomposition of a manifold  $M$  is given by:

(i) a sequence  $M = M_N \supset \dots \supset M_0$ , where each  $M_j$  is a sub-

manifold of  $M$ ;

(ii) diffeomorphisms  $\Phi_j: S^{\lambda_j-1} \times D^{n-\lambda_j} \rightarrow \partial M_k$ , and

$$\begin{aligned}\Psi_{j+1}: M_{j+1} &\longrightarrow M_j \cup_{\Phi_j} D^{\lambda_j} \times D^{n-\lambda_j}, \\ \Psi_0: M_0 &\longrightarrow D^n.\end{aligned}$$

A Morse function  $F: M \rightarrow \mathbf{R}$  together with a gradient-like vector field for  $F$ , determine a handlebody decomposition of  $M$  (cf. [6]).

Now let  $f: M \rightarrow S^2$  be a Lefschetz fibration with regular fiber  $X$ , where  $\dim X = 2n$ ,  $\dim M = 2n + 2$ . We will assume that 0 and  $\infty$  are regular values of  $f$ . Define  $F: M \rightarrow \mathbf{R} \cup \infty$  by  $F(p) = |f(p)|^2$ . Then it is easy to verify that outside of  $f^{-1}(0) \cup f^{-1}(\infty)$ ,  $F$  has only nondegenerate critical points, each of index  $n + 1$  (cf. [1]).

**DEFINITION 1.5.** The Lefschetz fibration  $f: M \rightarrow S^2$  is said to be normalized if the critical values of  $f$  are precisely the  $\mu$  roots of unity.

Every Lefschetz fibration is equivalent to a normalized Lefschetz fibration. Explicitly, if  $a_1, \dots, a_\mu \in S^2$  are the critical values of  $f$ , and if  $a \in S^2$  is a regular value of  $f$ , choose arcs  $\gamma_j$  from  $a$  to  $a_j$ ,  $j = 1, \dots, \mu$ , which do not intersect except at  $a$ . Construct an orientation preserving diffeomorphism between a regular neighborhood of  $\bigcup_{j=1}^\mu \gamma_j$  and the disk of radius  $1 + \varepsilon$  such that  $a_j$  is mapped to  $e^{2\pi i j / \mu}$ . Let  $g: S^2 \rightarrow S^2$  be an extension of this diffeomorphism. Then  $g \circ f: M \rightarrow S^2$  is a normalized Lefschetz fibration.

Now assume that  $f: M \rightarrow S^2$  is a normalized Lefschetz fibration, and let  $D_t \subset S^2$  denote the disk of radius  $t$  centered at the origin. Then  $f^{-1}(D_t) \cong X \times D^2$  for  $t < 1$ , while for  $t > 1$ ,  $f^{-1}(D_t)$  is diffeomorphic to the manifold obtained from  $X \times D^2$  by attaching  $\mu$   $(n + 1)$ -handles by means of imbedding  $\Phi_j: S^n \times D^{n+1} \rightarrow \partial(X \times D^2) = X \times S^1$ ,  $j = 1, \dots, \mu$ , where the  $\Phi_j$  have disjoint images.

**LEMMA 1.6.** *The imbeddings  $\Phi_j$  may be chosen so that  $\Phi_j(S^n \times 0) \subset f^{-1}(z_j)$  for some  $z_j$ ,  $j = 1, \dots, \mu$ .*

The proof of Lemma 1.6 will be given together with the proof of Theorem 1.7.

Let  $\phi_j: S^n \rightarrow X$  be the imbedding defined by  $\Phi_j$  restricted to  $S^n \times 0$ , and the identification  $f^{-1}(D_t) \cong X \times D^2$ , for  $t < 1$ . Let  $\nu_i$  denote the normal bundle of  $S^n$  in  $X$  corresponding to the imbedding  $\phi_j$ , and let  $\nu$  denote the normal bundle of  $S^n$  in  $F^{-1}(1 - \varepsilon)$ . Clearly we have  $\nu \cong \nu_1 \oplus \varepsilon$ . Let  $\tau$  denote the tangent bundle of  $S^n$ .

**THEOREM 1.7.** *There exists a bundle isomorphism  $\phi'_j: \tau \rightarrow \nu_1$ . The framing  $\phi'_j: \varepsilon^{n+1} \rightarrow \nu$  coincides with the isomorphism.*

$$\varepsilon^{n+1} \xrightarrow{\sim} \tau \oplus \varepsilon \xrightarrow{\phi'_j \oplus 1} \nu_1 \otimes \varepsilon \xrightarrow{\sim} \nu.$$

Moreover  $\phi'_j$  is determined, up to smooth isotopy, by the local behavior of the function  $f$  at the critical point  $p$ .

The proof of Lemma 1.6 and Theorem 1.7 are based on the following easy lemma.

**LEMMA 1.8.** *Let  $f: \mathbf{R}^n \rightarrow \mathbf{R}$  be a smooth function, and let  $a = (a_1, \dots, a_n)$  be a regular point of  $f$ . Let  $f(x) = f(a) + L(x - a) + R(x - a)$  where  $L(x)$  is a linear function and  $|R(x - a)| \leq k|x - a|^2$  for  $|x - a|$  sufficiently small. Then for  $\varepsilon > 0$  sufficiently small, there exists a smooth function  $F: \mathbf{R}^n \times I \rightarrow \mathbf{R}$  satisfying:*

- (i)  $F(x, 0) = f(x)$ ;
- (ii)  $F(x, t) = f(x)$  for  $|x - a| > \varepsilon$ ;
- (iii)  $F(x, 1) = f(a) + L(x - a)$  for  $|x - a| < \varepsilon/2$ ;
- (iv)  $x \rightarrow F(x, t)$  has no critical points in  $\{|x - a| < \varepsilon\}$ .

*Proof.* We may assume that  $x = 0$ , and  $f(a) = 0$ . Let  $\rho_\varepsilon(s)$  be a smooth function such that

$$\rho_\varepsilon(s) = \begin{cases} 1, & s < \varepsilon/2 \\ 0, & s > \varepsilon \end{cases}.$$

Let  $F(x, t) = (tL(x) + (1 - t)f(x))\rho_\varepsilon(|x|) + f(x)(1 - \rho_\varepsilon(|x|))$ . It is obvious that  $F$  satisfies conditions (i), (ii), and (iii). To check condition (iv), we restrict our choice of  $\rho_\varepsilon(s)$ . Let  $\rho(s)$  be a smooth function such that  $\rho(s) = \begin{cases} 1, & s \leq 1/2 \\ 0, & s \geq 1 \end{cases}$ . Then set  $\rho_\varepsilon(s) = \rho(s/\varepsilon)$ . Let  $M$  be a constant such that  $|\rho'(s)| \leq M$ . Then  $|\rho'_\varepsilon(s)| \leq M/\varepsilon$ . Letting  $\vec{\nabla} f = (\partial f / \partial x_1, \dots, \partial f / \partial x_n)$ , and defining  $F_i(x) = F(x, t)$  we have:

$$\vec{\nabla} F_i(x) = -t\rho_\varepsilon(|x|)\vec{\nabla} R(x) - tR(x)\rho'_\varepsilon(|x|)\frac{\vec{x}}{|x|} + \vec{\nabla} f$$

where  $\vec{x} = (x_1, \dots, x_n)$ . The first term on the right is small for small values of  $\varepsilon$  since  $\vec{\nabla} R(x) \rightarrow 0$  as  $x \rightarrow 0$ . As for the second term, we have  $|R(x)| < k\varepsilon^2$  and  $|\rho'_\varepsilon(x)| \leq M/\varepsilon$  for  $|x| < \varepsilon$ . Finally,  $\vec{\nabla} f(0) \neq 0$  since 0 is a regular point. Therefore for  $\varepsilon$  sufficiently small  $\vec{\nabla} F_i(x) \neq 0$  for  $|x| < \varepsilon$ .

*Proof of Lemma 1.6 and Theorem 1.7.* Assume, for simplicity, that  $j = 1$ . Since the Morse function  $F$  is the composition of the Lefschetz fibration  $w \rightarrow f(w)$ , and the function  $z \rightarrow |z|^2$ , we can find, by Lemma 1.8, an arc of Morse functions  $F_i: M \rightarrow \mathbf{R}$  such that

- (i)  $F_i$  coincides with  $F$  on  $\{w \in M \mid |f(w) - 1| > \varepsilon\}$

(ii)  $F_0 = F$

(iii)  $F_1(w) = 2\operatorname{Re} f(w) - 1$  on  $\{w \in M \mid |f(w) - 1| \leq \varepsilon/2\}$ .

Since  $F_1$  can be connected to  $F_0$  by an arc of Morse functions, the handlebody decomposition associated with  $F_1$  differs from that associated with  $F_0$  by a smooth isotopy. Now if we use local complex coordinates  $(w_1, \dots, w_{n+1})$  in a neighborhood of the critical point  $p_1$  such that:  $f(w_1, \dots, w_{n+1}) = 1 + w_1^2 + \dots + w_{n+1}^2$ , then  $F_1(w) = 2\operatorname{Re} f(w) - 1 = 1 + 2|u|^2 - 2|v|^2$  where  $w = u + iv$ ,  $u, v \in \mathbf{R}^{n+1}$ . Then  $\Phi_1(S^n \times 0) = \{(u, v) \mid |u| = 0, 1 - 2|v|^2 = 1 - \varepsilon\} \subset f^{-1}(\sqrt{1 - \varepsilon})$ , which proves Lemma 1.6.

To prove Theorem 1.7, consider the function:  $g: S^n \times \mathbf{R}^{n+1} \rightarrow \mathbf{R}$  defined by  $g(\xi, \eta) = \xi \cdot \eta$ .  $g^{-1}(0)$  is the total space of the tangent bundle to  $S^n$ ; thus if  $\nu_1$  is the normal bundle of  $S^n \times 0$  in  $g^{-1}(0)$ , then  $\nu_1$  is naturally isomorphic to  $\tau = \tau_{S^n}$ . Since  $g$  is a fibration, the normal bundle to  $g^{-1}(0)$  in  $S^n \times \mathbf{R}^{n+1}$  is trivial. Restricting these bundles to  $S^n \times 0$ , and using the standard metric on  $S^n \times \mathbf{R}^{n+1}$ , we get the splitting of bundles on  $S^n$ ,  $\varepsilon^{n+1} \cong \tau \oplus \varepsilon$ . An easy computation shows that this coincides with the splitting induced by the standard imbedding of  $S^n$  in  $\mathbf{R}^{n+1}$ . Now consider the diagram:

$$\begin{array}{ccc} S^n \times D^{n+1} & \xrightarrow{\phi} & F_1^{-1}(1 - \varepsilon) \\ g \downarrow & & \downarrow \operatorname{Im} f \\ \mathbf{R} & \xrightarrow{\sqrt{2\varepsilon}} & \mathbf{R} \end{array}$$

The diagram does not commute, but it does “commute to first order” on  $S^n \times 0$ . More precisely, this diagram induces a commutative diagram of bundle maps which proves Theorem 1.7.

**DEFINITION 1.8.**  $\phi_j(S^n) \subset X$  is called a vanishing cycle for the Lefschetz fibration  $f: M \rightarrow S^2$ . The bundle isomorphism  $\phi'_j: \tau \rightarrow \nu$  will be called a normalization of  $\phi_j$ . The pair  $\tilde{\phi}_j = (\phi_j, \phi'_j)$  will be called a normalized vanishing cycle. The sequence of normalized vanishing cycles,  $(\tilde{\phi}_1, \dots, \tilde{\phi}_\mu)$  will be called an admissible sequence of normalized vanishing cycles.

Note that the bundle isomorphism  $\phi': \tau \rightarrow \nu$  preserves or reverses orientations according to the factor  $(-1)^{n(n-1)/2}$ . Thus, e.g., if  $X$  is a real oriented surface, then a normalized vanishing cycle is completely determined by an imbedded circle. If  $X$  is an oriented 4 manifold, the “core” of a normalized vanishing cycle is an imbedded  $S^2$  with self intersection  $-2$ .

Consider the case where  $\dim M = 4$ , and therefore  $X$  is an oriented surface. A vanishing cycle is then an imbedded circle in  $X$ , and the normalization of each vanishing cycle is unique. If

$f: M \rightarrow S^2$  is a Lefschetz fibration, then for a sufficiently large disk  $G \subset S^2$ ,  $f^{-1}(G)$  is diffeomorphic to the manifold obtain from  $X \times D^2$  by attaching a finite number of 2-handles using attaching maps  $\Phi_j: S^1 \times D^2 \rightarrow X \times S^1$ ,  $j = 1, \dots, \mu$ , where  $\Phi_j(S^1 \times 0)$  is an imbedded circle  $\gamma_j$ , in a fiber  $X \times c_j$  of  $X \times S^1$ . Now there is a natural way to trivialize the normal bundle of  $\gamma_j$  in  $X \times S^1$  corresponding to the fact that the normal bundle of  $\gamma_j$  in  $X$  is trivial, and the normal bundle of  $X$  in  $X \times S^1$  is trivial. However, our Theorem 1.7 states that the framing  $\Phi'_j: \varepsilon^2 \rightarrow \nu$  is obtained by identifying the normal bundle of  $\gamma_j$  in  $X$  with the tangent bundle  $\tau$  of  $\gamma_j$  and then using the isomorphism

$$\varepsilon^2 \cong \tau \oplus \varepsilon.$$

If one also pays attention to orientations, it is not hard to see that, relative to the “natural” framing,  $\Phi'_j: \varepsilon^2 \rightarrow \nu$  has framing  $-1$ . In other words, if we identify  $\nu$  with  $\varepsilon^2$  by the “natural” framing, then  $\Phi'_j: \varepsilon^2 \rightarrow \nu$  is given by the mapping  $S^1 \rightarrow SO(2) \cong S^1$  of degree  $-1$ . This explains the well known fact (??) in algebraic geometry that relative vanishing cycles have self intersection number  $-1$ .

**2. Invariants of a Lefschetz fibration.** Let  $TS^n(1)$  denote the closed tangent unit disk bundle to  $S^n$ . We wish to describe a diffeomorphism

$$\delta: TS^n(1) \longrightarrow TS^n(1)$$

such that:

- (i)  $\delta$  is the identity on the boundary of  $TS^n(1)$ ; and
- (ii)  $\delta$  is the antipodal map on  $S^n \subset TS^n(1)$ .

Let  $(p, v) \in TS^n(1)$ , where  $p \in S^n$  and  $v \in TS_p^n$  is a tangent vector of length  $\leq 1$ . Form the geodesic arc on  $S^n$  with initial point  $p$ , initial velocity  $v$ , and length  $\pi|v|$ , where  $|v|$  denotes the length of  $v$ . Let  $q$  be the end point, and  $w$  the terminal velocity of this arc. Then we put  $\delta(p, v) = (q^*, w^*)$  where  $(q^*, w^*)$  is the image of  $(q, w)$  under the antipodal map.

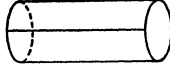

Now let  $X$  be a closed manifold of dimension  $2n$ ; let  $\phi: S^n \rightarrow X$  be an imbedding, and let  $\phi': \tau \rightarrow \nu$  be a bundle isomorphism where  $\tau$  is the tangent bundle to  $S^n$ , and  $\nu$  is the normal bundle of  $S^n$  in  $X$ . By the tubular neighborhood theorem,  $\phi'$  induces a diffeomorphism between  $TS^n(1)$  and a tubular neighborhood of  $\phi(S^n)$  in  $X$ . Thus we can apply  $\delta$  to a tubular neighborhood of  $\phi(S^n)$  in  $X$ , and after smoothing near the boundary, we can extend  $\delta$  by the identity to a diffeomorphism of  $X$  which we denote

$$\delta_{\phi, \phi'}: X \longrightarrow X.$$

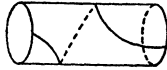

Note that up to smooth isotopy  $\delta_{\phi, \phi'}$  only depends on the smooth isotopy class of the imbedding  $\phi$  and the bundle isomorphism  $\phi'$ .

DEFINITION 2.1.  $\delta_{\phi, \phi'}$  is called the Dehn twist of  $X$  with center  $(\phi, \phi')$ .

Notice that if  $\dim X = 2$ , then  $\delta_{\phi, \phi'}$  is the classical right handed Dehn twist, i.e.,  $\delta_{\phi, \phi'}$  maps the cylinder

to

Now let  $f: M \rightarrow S^2$  be a Lefschetz fibration with regular fiber  $X$ , and let  $p \in M$  be a critical point of  $f$ . The part of  $M$  which lies over the boundary of a small disk about  $f(p)$  is then a fiber bundle over  $S^1$  with typical fiber  $X$ . It is well known that such a fiber bundle is diffeomorphic to  $X \times I / (x, 1) \sim (h(x), 0)$  where  $h: X \rightarrow X$  is a diffeomorphism which is uniquely defined up to smooth isotopy.  $h$  is the geometric monodromy of the fibering  $f: M \rightarrow S^2$ , associated with the critical value  $f(p)$ . Assume now that  $p$  is the only critical point with critical value  $f(p)$ . Then as in §1, we may construct an imbedding  $\phi: S^n \rightarrow X$ , and normalization  $\phi': \tau \rightarrow \nu$ .

THEOREM 2.1 (cf. [3], page 148). *The Dehn twist  $\delta_{\phi, \phi'}: X \rightarrow X$  is the geometric monodromy of  $M$  about  $f(p)$ .*

*Proof.* This theorem is proved in [3], but we will give another proof which is more consistent with our point of view. Let  $I = [-1, 1]$  and fix an imbedding  $\iota: I \rightarrow S^1$ , e.g.,  $t \mapsto e^{i\pi t}$ . Now given a Lefschetz fibration  $f: M \rightarrow S^2$  with critical value  $f(p)$ , choose a small circle  $\gamma$  about  $f(p)$ ; then  $f^{-1}(\gamma) = Y$  is the manifold obtained from  $X \times S^1$  by surgery. The surgery is performed as follows: look at  $\phi' \times \iota: TS^n(1) \times I \rightarrow X \times S^1$ .  $TS^n(1) \times I$  may be identified with  $S^n \times D^n$  in a standard way (this involves straightening corners). The surgery consists of removing  $S^n \times D^n = \phi' \times \iota(TS^n(1) \times I)$  and sewing it back in by the automorphism of the boundary  $S^n \times S^n$  given by  $(\xi, \eta) \rightarrow (\eta, \xi)$ .  $Y$  is given a differentiable structure by identifying  $Y$  with  $(X \times S^1 - \phi(S^n) \times \{1\}) \cup D^{n+1} \times S^n$  where  $(\xi', \eta') \in (D^{n+1} - 0) \times S^n$  is identified with a point of  $X \times S^1 - \phi(S^n) \times \{1\}$  by the following map: first send  $(\xi', \eta')$  to  $(\xi, \eta) = (\xi' / |\xi'|, |\xi'| \eta') \in S^n \times D^{n+1}$ ; then send  $(\xi, \eta)$  to  $(u, v) \times t \in TS^n(1) \times I$ , and finally send this point to  $\phi'(u, v) \times$

$\iota(t)$ . We may write

$$Y = (X \times S^1 - \phi(S^n) \times \{1\}) \bigcup_h TS^n(1) \times I$$

where  $h: TS^n(1) \times I - S^n \times \{0\} \rightarrow X \times S^1 - \phi(S^n) \times \{1\}$  is given as follows: if  $(u, v) \times t \in TS^n(1) \times I - S^n \times \{0\}$ , then  $h((u, v), t) = \phi'(u', v') \times \iota(t)$  where  $(u', v')$  are given by:

$$\begin{aligned} u' &= \frac{t}{\sqrt{t^2 + |v|^2}} u + \frac{1}{\sqrt{t^2 + |v|^2}} v \\ v' &= \frac{|v|^2}{\sqrt{t^2 + |v|^2}} u - \frac{t}{\sqrt{t^2 + |v|^2}} v. \end{aligned}$$

Thus the vector  $\begin{pmatrix} u' \\ v' \end{pmatrix}$  is the product of the vector  $\begin{pmatrix} u \\ v \end{pmatrix}$  by the matrix:

$$\begin{pmatrix} \frac{t}{\sqrt{t^2 + |v|^2}} & \frac{1}{\sqrt{t^2 + |v|^2}} \\ \frac{|v|^2}{\sqrt{t^2 + |v|^2}} & -\frac{t}{\sqrt{t^2 + |v|^2}} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & |v| \end{pmatrix} \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \\ \times \begin{pmatrix} 1 & 0 \\ 0 & |v|^{-1} \end{pmatrix}$$

where  $\theta = \arcsin t/\sqrt{t^2 + |v|^2}$ . These formulae show how the projection  $X \times S^1 - \phi(S^n) \times \{1\} \rightarrow S^1$  extends to a fibration  $f: Y \rightarrow S^1$  where  $f$  is defined on  $TS^n(1) \times I$  by  $f((u, v), t) = \iota(t)$ .

The mapping  $h: TS^n(1) \times I - S^n \times 0 \rightarrow TS^n(1) \times I - S^n \times 0$  given by  $(u, v, t) \mapsto (u', v', t)$  has the following geometric description: Given  $u \in S^n$  and  $v \neq 0$ ,  $v$  tangent to  $S^n$  at  $u$ , define  $(u', v')$  so that  $u'$  lies on the great circle through  $u$  in the direction  $v$  and the angle between  $u$  and  $u'$  is  $\theta + \pi/2$ .  $v'$  is tangent to the great circle, has the same length as  $v$  and points backwards towards  $u$ . For fixed  $t$ , as  $v$  approaches 0,  $\theta = \arcsin t/\sqrt{t^2 + |v|^2}$  approaches  $\pi/2$  for  $t > 0$  and  $-\pi/2$  for  $t < 0$ . Thus  $h|_{S^n \times \{t\}}$  is the identity for  $t < 0$  and the antipodal map for  $t > 0$ . For  $|v| = 1$ ,  $\theta = \theta(t)$  goes from  $-\pi/4$  to  $\pi/4$  as  $t$  goes from  $-1$  to  $1$ .

Now to calculate the geometric monodromy of  $f: Y \rightarrow S^1$ , we construct a flow on  $Y$ . This is accomplished by constructing a smooth map  $g: X \times [\varepsilon, 2\pi + \varepsilon] \rightarrow Y$  such that  $g(x, s) \in f^{-1}(e^{is})$  and  $g_s: X \rightarrow f^{-1}(e^{is})$  is a diffeomorphism (the flow is  $g_*(\partial/\partial s)$ ). The geometric monodromy is given by  $g_{2\pi+\varepsilon} \circ g_\varepsilon^{-1}$ .

Identifying  $Y$  with

$$X \times S^1 - \phi(S^n) \times \{1\} \bigcup_h TS^n(1) \times I$$

we first define  $g$  on  $X \times [\varepsilon, 2\pi + \varepsilon] - \phi'(TS^n(1/2)) \times [2\pi - \varepsilon/2, 2\pi + \varepsilon]$  by setting  $g(x, s) = (x, e^{is})$ . We extend  $g$  by a mapping  $\tilde{g}: TS^n(1) \times I \rightarrow TS^n(1) \times I$  such that on  $TS^n(1) \times I - TS^n(1/2) \times [-1/2, 1] h \circ g = \text{id}$ . To construct  $\tilde{g}$ , choose a smooth function  $\zeta(|v|, t)$  such that: (i)  $\zeta(|v|, t) = \theta(|v|, t)$  on  $\{t \leq -1/2\} \cup \{|v| \geq 1/2\}$  and (ii) for fixed  $t$ ,  $\zeta(|v|, t) \rightarrow -\pi/2$  as  $|v| \rightarrow 0$ . Now define  $\tilde{g}$  just as we defined  $h$ , but use  $\zeta$  instead of  $\theta$ . Specifically,

$$\tilde{g}((u, v), t) = \begin{cases} ((u, v), t) & \text{if } v = 0 \\ ((u', v'), t) & \text{if } v \neq 0 \end{cases}$$

where  $u'$  lies on the great circle through  $u$  in the direction  $v$ , the angle between  $u$  and  $u'$  is  $\pi/2 + \zeta$ , and  $v'$  points backwards towards  $u$  along this geodesic and has the same length as  $v$ .

To calculate the monodromy  $g_{2\pi+\varepsilon} \circ g_\varepsilon^{-1}$ , it is clear that the monodromy is concentrated on  $TS^n(1) \subset X$ , i.e., it is the identity outside of  $TS^n(1)$ . Notice that  $g_\varepsilon$  is defined by the following diagram:

$$\begin{array}{ccc} X = X - S^n \bigcup_{\text{id}} TS^n(1) & & \\ g_\varepsilon \downarrow & \text{id} \downarrow & \downarrow h_1^{-1} \\ f^{-1}(e^{i\varepsilon}) = X - S^n \bigcup_{h_1} TS^n(1) & & \end{array}$$

where  $h_t = h|_{TS^n(1) \times t} \circ g_{2\pi+\varepsilon}$  is defined by:

$$\begin{array}{ccc} X = X - S^n \bigcup_{\text{id}} TS^n(1) & & \\ g_{2\pi+\varepsilon} \downarrow & \downarrow \text{id} & \downarrow \tilde{g}_1 \\ f^{-1}(e^{i\varepsilon}) = X - S^n \bigcup_{h_1} TS^n(1) & & \end{array}$$

Thus the geometric monodromy  $g_{2\pi+\varepsilon} \circ g_\varepsilon^{-1}$  is concentrated on  $TS^n(1) \subset X$  and there it is equal to  $\tilde{g}_1^{-1} \circ h_1$ . This mapping sends a point  $(u, v) \in TS^n(1)$  to  $(u', v')$  where  $u'$  lies on the great circle through  $u$  tangent to  $v$ ,  $|v'| = |v|$ , and the angle between  $u$  and  $u'$  is  $\phi(|v|, 1) - \zeta(|v|, 1)$ . This angle is a decreasing function of  $|v|$ , equal to  $\pi$  for  $|v| = 0$  and equal to 0 for  $|v| = 1$ . This map is therefore isotopic to the Dehn twist  $\delta_{\phi, \phi'}$ .

Let  $f: M \rightarrow S^2$  be a normalized Lefschetz fibration with fiber  $X$ , and critical values  $e^{2\pi i j/\mu}$ ,  $j = 0, 1, \dots, \mu - 1$ . Let  $E$  denote the subset of the disk of radius  $1 + \varepsilon$  obtained by removing the sets  $E_j$ ,  $j = 1, \dots, \mu$  where  $E_j$  is described in polar coordinates  $(r, \theta)$  by:

$$E_j = \{(r, \theta) | 1 - \varepsilon < r \leq 1 + \varepsilon, \frac{2\pi j}{\mu} - \varepsilon < \theta < \frac{2\pi j}{\mu} + \varepsilon\}.$$

Identifying  $f^{-1}(E)$  with  $X \times E$ , one may construct a vector field  $\sigma$  on  $f^{-1}\{|z| = 1 + \varepsilon\}$  such that  $\sigma = (0, \partial/\partial\theta)$  outside of the  $E_j$ , while on  $E_j$  the flow along  $\sigma$  maps the fiber over  $\theta = 2\pi j/\mu - \varepsilon$  to the fiber over  $\theta = 2\pi j/\mu + \varepsilon$  by a Dehn twist  $\delta_j$ ,  $j = 1, \dots, \mu$ . In particular, if we let  $X_\theta$  denote the fiber over  $\theta$ , then the flow along  $\sigma$  defines diffeomorphisms,

$$h_\theta: X_0 \longrightarrow X_\theta \text{ such that,}$$

$$h_{2\pi} = \delta_\mu \circ \dots \circ \delta_1. \text{ Since } f \text{ has no critical}$$

values outside the unit circle, the fibration defined by  $f$  may be trivialized over the complement of  $E$ . In particular each fiber  $X_\theta$  is then identified with  $X = X_0$ , and  $\theta \rightarrow h_\theta$  may be regarded as an arc in  $\text{Diff}(X)$  joining the identity to  $\delta_\mu \circ \dots \circ \delta_1$ . Any two such trivializations of the fibering  $f$  are related by a diffeomorphism

$$D^2 \times X \longrightarrow D^2 \times X$$

of the form:  $(z, x) \rightarrow (z, g_z(x))$ . The function  $D^2 \rightarrow \text{Diff}(X)$  given by  $z \rightarrow g_z$  gives a homotopy between the arcs  $\theta \rightarrow h_\theta$ , corresponding to the two trivializations. Thus the homotopy class of the arc  $\theta \rightarrow h_\theta$  is an invariant of the normalized Lefschetz fibration  $f: M \rightarrow S^2$ .

**THEOREM 2.3.** *The normalized Lefschetz fibration  $f: M \rightarrow S^2$  is uniquely determined by:*

- (1) *a sequence of normalized vanishing cycles  $(\tilde{\phi}_1, \dots, \tilde{\phi}_n)$ ; and*
- (2) *a homotopy class of arcs  $\theta \rightarrow h_\theta$  in  $\text{Diff}(X)$ , where  $h_0 = \text{id}_X$  and  $h_{2\pi} = \delta_\mu \circ \dots \circ \delta_1$ , where  $\delta_j = \delta_{\tilde{\phi}_j}$  is the Dehn twist of  $X$  with center  $\tilde{\phi}_j$ .*

*Proof.* This theorem is essentially a direct consequence of Theorem 1.7, and our above discussion. More precisely, the manifold  $M$  and the fibration  $f$  are constructed as follows: starting with  $D^2 \times X$ , one attaches  $\mu$   $(n+1)$ -handles along the centers  $\Phi_{j_0}: S^n \rightarrow \varepsilon_j \times X$ ,  $\varepsilon_j = e^{2\pi i j/\mu}$ , where  $\Phi_{j_0}$  coincides with  $\phi_j: S^n \rightarrow X$ , and the framing of  $\Phi_{j_0}$  is given by the prescription of Theorem 1.7. The boundary of the resulting manifold fibers over a circle, with fiber  $X$ , and by Theorem 2.1, one may construct a vector field on this boundary whose flow gives rise to the diffeomorphism  $\delta_\mu \circ \dots \circ \delta_1$ . The smooth arc  $\theta \rightarrow h_\theta$  in  $\text{Diff}(X)$  joining  $\text{id}_X$  to  $\delta_\mu \circ \dots \circ \delta_1$  is then used to identify the boundary with  $S^1 \times X$ , and we finally use this identification to close up the manifold by attaching a copy of  $D^2 \times X$ .

The normalized vanishing cycle  $\tilde{\phi}$  was defined (Def. 1.8) as a

pair  $(\phi, \phi')$  where  $\phi: S^n \rightarrow X$  is an imbedding, and  $\phi': \tau_{S^n} \rightarrow \nu$  is a bundle isomorphism.  $\phi$  and  $\phi'$  are defined up to smooth isotopy. The distinct bundle isomorphisms  $\tau_{S^n} \rightarrow \nu$  are classified, up to isotopy, by the group  $\pi_n(SO(n))$ . Thus for those values of  $n$  for which  $\pi_n(SO(n)) = 0$ ,  $\phi'$  is uniquely determined. This is true, in particular, for  $n = 1$  and  $2$ .

Given an admissible sequence  $(\tilde{\phi}_1, \dots, \tilde{\phi}_\mu)$ , let  $M_1$  be the manifold with boundary obtained by attaching  $\mu$   $(n+1)$ -handles to  $D^2 \times X$  as in Theorem 1.7. The distinct homotopy classes of arcs  $\theta \rightarrow h_\theta$  in  $\text{Diff}(X)$  joining  $\text{id}_X$  to  $\delta_\mu \circ \dots \circ \delta_1$  are classified by  $\pi_1(\text{Diff}(X))$ . Now a closed loop in  $\text{Diff}(X)$  gives rise to a fiber preserving diffeomorphism of  $S^1 \times X$ , and a homotopy class corresponds to an isotopy class of such fiber preserving diffeomorphisms. Let  $\{\theta \rightarrow h_\theta\}, \{\theta \rightarrow h'_\theta\}$  be two homotopy classes of arcs in  $\text{Diff}(X)$  joining  $\text{id}_X$  to  $\delta_\mu \circ \dots \circ \delta_1$  and  $g: S^1 \times X \rightarrow S^1 \times X$  be a diffeomorphism representing their difference. If  $g$  can be extended to a fiber preserving diffeomorphism of  $M_1$ , then the Lefschetz fibering,  $f: M \rightarrow S^2$  associated to  $h_\theta$  is equivalent to the Lefschetz fibration  $f': M' \rightarrow S^2$  associated to  $h'_\theta$ .

**THEOREM 2.4.** *If  $X$  is an oriented surface of genus  $> 1$ , then every Lefschetz fibration  $f: M \rightarrow S^2$  with fiber  $X$  is uniquely determined, up to equivalence, by an admissible sequence of vanishing cycles. In case  $X$  has genus  $1$ , the theorem is still true provided that  $f: M \rightarrow S^2$  has at least one vanishing cycle  $\phi: S^1 \rightarrow X$  which is not homologous to zero.*

*Proof.* It is clear that there is a unique normalization for any vanishing cycle in a surface (cf. the remarks on orientation, following Def. 1.8). The theorem in the case of genus  $(X) > 1$  follows from the fact that  $\text{Diff}(X)$  is contractible (cf. [4]). The case, genus  $(X) = 1$ , follows from results of Moishezon [10] (Lemma 8 on page 179 and Lemma 7 on page 164).

It follows from Theorem 2.4, that to each equation of the form:

$$\delta_\mu \circ \dots \circ \delta_1 = 1$$

in the mapping class group of the oriented surface  $X$ , where  $\delta_j$  is the right-handed Dehn twist of  $X$ , centered at some circle  $\gamma_j$  in  $X$ , one may associate a 4-manifold  $M$  and a normalized Lefschetz fibration  $f: M \rightarrow S^2$  whose critical values are the  $\mu$  roots of unity and whose vanishing cycles are  $\gamma_1, \gamma_2, \dots, \gamma_\mu$ . Let  $g: S^2 \rightarrow S^2$  be an orientation preserving diffeomorphism which leaves invariant the  $\mu$  roots of unity. Then  $f' = g \circ f: M \rightarrow S^2$  is a normalized Lefschetz fibration with vanishing cycles  $\gamma'_1, \dots, \gamma'_\mu$ . Following [10], page 180, we

will say that the admissible sequence  $(\gamma'_1, \dots, \gamma'_\mu)$  is equivalent to  $(\gamma_1, \dots, \gamma_\mu)$ . This relation is generated by the elementary transformations:

$$T_j: (\gamma_1, \dots, \gamma_\mu) \longrightarrow (\gamma'_1, \dots, \gamma'_\mu)$$

where:

$$\begin{aligned}\gamma'_j &= \delta_j^{-1}(\gamma_{j+1}) \\ \gamma'_{j+1} &= \gamma_j \\ \gamma'_k &= \gamma_k \quad \text{if } k \neq j, j+1\end{aligned}$$

(here the subscript  $j$  is computed modulo  $\mu$ ). The corresponding Dehn twists  $\delta'_k$  are given by:

$$\begin{aligned}\delta'_j &= \delta_j \circ \delta_{j+1} \circ \delta_j^{-1} \\ \delta'_{j+1} &= \delta_j \\ \delta'_k &= \delta_k \quad \text{if } k \neq j \text{ or } j+1.\end{aligned}$$

EXAMPLE 2.5. Let  $X = T^2$  be a surface of genus 1, i.e., a 2-dimensional torus. Let  $m$  denote a standard meridian circle, and let  $l$  denote a standard longitude on  $X$ . Let  $(\gamma_1, \dots, \gamma_\mu)$  be an admissible sequence of imbedded circles on  $X$ , such that no  $\gamma_j$  is homologous to zero. Then Moishezon has proved (cf. [10]) that  $\mu \equiv 0 \pmod{12}$  and  $(\gamma_1, \dots, \gamma_\mu)$  is equivalent to the sequence  $(m, l, \dots, m, l)$  ( $\mu$  terms).

3. Some open problems. In this section we will discuss several problems on Lefschetz fibrations of 4-manifolds. Such fibrations arise naturally from Lefschetz pencils. Thus let  $M$  be an algebraic surface imbedded algebraically in a complex projective space  $P^N$ . Let  $H^{N-2}$  be a generic linear space of codimension 2 in  $P^N$ , and let  $\tilde{M}$  be the manifold obtained from  $M$  by blowing up the points of  $M \cap H^{N-2}$ . Then there is a Lefschetz fibration  $f: \tilde{M} \rightarrow P^1$  such that  $f^{-1}(t) \cong M \cap L_t$ , where  $L_t \subset P^N$  is a hyperplane containing  $H^{N-2}$  (such hyperplanes are naturally parametrized by  $P^1$ ). For the details of this construction cf [1]. By Theorem 2.4, the differentiable structure of  $\tilde{M}$  together with the Lefschetz fibration is completely determined by an admissible sequence of vanishing cycles.  $M$  is obtained from  $\tilde{M}$  by blowing down certain exceptional curves. These exceptional curves are holomorphic sections of the fibration  $f: \tilde{M} \rightarrow P^1$  with self intersection  $-1$ . Moreover if we assume that  $M$  is a minimal surface and that  $M$  is neither rational nor ruled, then  $M$  is obtained from  $\tilde{M}$  by blowing down all holomorphic sections of  $f: \tilde{M} \rightarrow P^1$  of self intersection  $-1$ . We do not know whether every continuous section with self intersection  $-1$  is homotopic to

a holomorphic section. This leads to the following problem:

*Problem 3.1.* Is the differentiable structure of an algebraic surface  $M$  (minimal, not rational or ruled) determined by an admissible sequence of vanishing cycles arising from a Lefschetz pencil?

Let  $f_1: M_1 \rightarrow S^2$  and  $f_2: M_2 \rightarrow S^2$  be two Lefschetz fibrations whose regular fibers are oriented surfaces of genus  $g$ . Choose regular fibers  $f_1^{-1}(a) \in M_1$  and  $f_2^{-1}(b) \in M_2$ , and a diffeomorphism  $\alpha: f_1^{-1}(a) \rightarrow f_2^{-1}(b)$ . We may construct a new Lefschetz fibration  $f_1 \#_\alpha f_2: M_1 \#_\alpha M_2 \rightarrow S^2$  as follows: Let  $T_1 \cong f_1^{-1}(a) \times D^2$  be a tubular neighborhood of  $f_1^{-1}(a)$  in  $M_1$ , and let  $T_2 \cong f_2^{-1}(b) \times D^2$  be a tubular neighborhood of  $f_2^{-1}(b)$  in  $M_2$ . Then  $M_1 \#_\alpha M_2$  is the union of  $M_1 - \text{int}(T_1)$  with  $M_2 - \text{int}(T_2)$  where we identify the boundaries by the mapping  $f_1^{-1}(a) \times S^1 \rightarrow f_2^{-1}(b) \times S^1$  which sends  $(x, z)$  to  $(\alpha(x), \bar{z})$ . The mapping  $f_1 \# f_2$  is defined in an obvious way.  $f_1 \# f_2: M_1 \#_\alpha M_2 \rightarrow S^2$  will be called a fiber connected sum of  $f_1: M_1 \rightarrow S^2$  and  $f_2: M_2 \rightarrow S^2$ . In general  $M_1 \#_\alpha M_2$  will depend on the diffeomorphism  $\alpha$ . It is not hard to see that if  $\alpha, \beta: f_1^{-1}(a) \rightarrow f_2^{-1}(b)$  are two diffeomorphisms, then  $M_1 \#_\alpha M_2$  is equivalent (in the sense of Lefschetz fibrations) to  $M_1 \#_\beta M_2$  if either  $\alpha^{-1} \circ \beta: f_1^{-1}(a) \rightarrow f_1^{-1}(a)$  is in the image of the (geometric) monodromy group of  $M_1$ , or if  $\alpha \circ \beta^{-1}: f_2^{-1}(b) \rightarrow f_2^{-1}(b)$  is in the image of the (geometric) monodromy group of  $M_2$ .

**DEFINITION 3.2.** We will say that a Lefschetz fibration  $f: M \rightarrow S^2$  is irreducible if it is not equivalent to a fiber connected sum  $f_1 \# f_2: M_1 \#_\alpha M_2 \rightarrow S^2$  where both  $f_1$  and  $f_2$  have at least one critical point. Algebraically, an irreducible Lefschetz fibration with regular fiber  $X$  is determined by an equation:  $\delta_\mu \cdots \delta_1 = 1$  in the mapping class group of  $X$  such that  $\delta_\mu \cdots \delta_1$  is not equivalent (in the sense given at the end of § 2) to  $\delta'_\mu \cdots \delta'_{\nu+1} \delta'_\nu \cdots \delta'_1$  where  $\delta'_\nu \circ \cdots \circ \delta'_1 = 1$  and  $\delta'_\mu \circ \cdots \circ \delta'_{\nu+1} = 1$ .

*Problem 3.3.* For a given surface  $X$  and integer  $\mu > 0$ , are there only finitely many (up to equivalence) irreducible Lefschetz fibrations  $f: M \rightarrow S^2$  with  $\mu$  vanishing cycles.

**REMARK 3.4.** The result of Moishezon (Example 2.5) states that if genus  $X = 1$ , then there is only one irreducible Lefschetz fibration  $f: M \rightarrow S^2$  where the number  $\mu$  of critical points, is 12. In this case, every element of the mapping class group of  $X$  is realized by a geometric monodromy, and therefore every Lefschetz fibration of genus 1 is equivalent to  $M \# \cdots \# M$ .

If the answer to problem 3.1 is "yes", we would like to use Lefschetz pencils to study the diffeomorphism types of algebraic

surfaces. Specifically, let  $M$  be an algebraic surface, minimal, not rational or ruled, and let  $f: \tilde{M} \rightarrow P^1$  be a Lefschetz fibration arising from a Lefschetz pencil on  $M$ . We have given a procedure for obtaining a handlebody decomposition of  $\tilde{M}$ . We would like to have such a decomposition for  $M$ . This could be done if it were possible to rearrange our handlebody decomposition, by sliding handles, so that the sections of  $f: \tilde{M} \rightarrow P^1$  of self intersection  $-1$  would occur as the cores of 2-handles.

*Problem 3.4.* Can the handlebody decomposition of  $f: \tilde{M} \rightarrow P^1$  be altered so as to obtain a handlebody decomposition of  $M$ ?
