WEAKLY ALMOST PERIODIC SEMIGROUPS OF OPERATORS

W. M. RUESS AND W. H. SUMMERS

We address the question as to when a motion or almost-orbit u of a strongly continuous semigroup $(S(t))_{t \geq 0}$ of operators in a Banach space X will be weakly almost periodic in the sense of Eberlein. In particular, we show (a) that this is the case in practice exactly when u uniquely decomposes as the sum $u = S(\cdot)y + \varphi$ of an almost periodic motion $S(\cdot)y: \mathbb{R}^+ \rightarrow X$ of $(S(t))_{t \geq 0}$ and a function $\varphi: \mathbb{R}^+ \rightarrow X$ that vanishes at infinity in a certain weak sense, and (b) that an almost-orbit u of a uniformly bounded C_0 -semigroup of linear operators will be weakly almost periodic provided only that u has weakly relatively compact range. Our results on existence and representation are then applied to a qualitative study of asymptotic behavior of solutions to the abstract Cauchy problem in which the focus is on almost periodicity properties and ergodic theorems.

Introduction. The point of departure for our work in this paper is the problem of distinguishing properties related to almost periodicity for solutions to the abstract Cauchy problem associated with the generator of a strongly continuous semigroup $(S(t))_{t \geq 0}$ of operators in a Banach space X . In the homogeneous case, solutions can be realized as motions of $(S(t))_{t \geq 0}$, and so the study of their asymptotic behavior reduces to a corresponding study of semigroup motions. Since weak or integral solutions to the inhomogeneous problem are almost-orbits of the associated semigroup in many concrete instances, moreover, we include almost-orbits as well as motions of $(S(t))_{t \geq 0}$ within the scope of our investigation.

In [21] (and the survey article [22]), we have treated the problem of characterizing motions that are asymptotically almost periodic; i.e., those for which their set of translates is relatively compact in the sup-normed space $(C_b(\mathbb{R}^+, X), \|\cdot\|_\infty)$ of all bounded continuous functions from \mathbb{R}^+ into X . Our present purpose is a study of motions and almost-orbits that are weakly almost periodic in the sense of Eberlein [9], which corresponds to the set of translates being relatively compact with respect to the weak topology of the Banach space $(C_b(\mathbb{R}^+, X), \|\cdot\|_\infty)$. Following a preliminary section, we show in §2 that (a) an almost-orbit $u: \mathbb{R}^+ \rightarrow X$ of $(S(t))_{t \geq 0}$ is weakly almost pe-

riodic if and only if there exist a unique element y in the weak ω -limit set of u and a uniquely determined Eberlein-weakly almost periodic function $\varphi: \mathbb{R}^+ \rightarrow X$ with the zero function in the weak closure of its set of translates such that $u = S(\cdot)y + \varphi$ and $S(\cdot)y: \mathbb{R}^+ \rightarrow X$ is almost periodic (Theorem 2.4), and (b) every almost-orbit with weakly relatively compact range of a uniformly bounded C_0 -semigroup of linear operators is weakly almost periodic (Theorem 2.1). In §3, we then apply our results to the questions of existence and representation of weakly almost periodic and almost periodic solutions to the abstract Cauchy problem.

1. Preliminaries. Throughout the paper, X will denote a (real or complex) Banach space, which we shall tacitly assume to be complex whenever spectral properties of linear operators enter the picture. The dual of X will be denoted by X^* , and B_{X^*} will denote the dual unit ball. For a subset D of X , the closure and weak closure of D will be denoted by $\text{cl } D$ and $\text{w-cl } D$, respectively, while $\text{co } D$ will denote the convex hull of D . Furthermore, $(S(t))_{t \geq 0}$ will hereafter denote a strongly continuous semigroup of operators on a weakly closed subset C of X .

For a function $u: \mathbb{R}^+ \rightarrow X$, we will refer to $\gamma(u) = \{u(t): t \geq 0\}$ as the orbit of u and to $\omega_w(u) = \{y \in X: \exists 0 \leq t_n \rightarrow \infty \text{ such that } u(t_n) \rightarrow y \text{ weakly in } X\}$ as the weak ω -limit set of u . In case $u = S(\cdot)x$ is a semigroup motion through some $x \in C$, however, we shall follow the standard practice of denoting these sets by $\gamma(x)$ and $\omega_w(x)$, respectively.

1.1. DEFINITION [19, p. 351]. A continuous function $u: \mathbb{R}^+ \rightarrow C$ is said to be an *almost-orbit* of $(S(t))_{t \geq 0}$ if

$$\lim_{t \rightarrow \infty} \sup_{h \in \mathbb{R}^+} \|u(t+h) - S(h)u(t)\| = 0.$$

As mentioned in the Introduction, the broader concept of an almost-orbit (which might more aptly be termed an almost motion) of a semigroup includes weak or integral solutions to certain classes of the inhomogeneous Cauchy problem associated with a generator $A: \mathcal{D}(A) \subseteq X \rightarrow X$ of a strongly continuous semigroup $(S(t))_{t \geq 0}$ of operators on $C = \text{w-cl } \mathcal{D}(A)$, and we pause to note two specific instances:

1.1.1. Assume that $(S(t))_{t \geq 0}$ is a uniformly bounded C_0 -semigroup of continuous linear operators on X , and let $x \in X$. If $f \in L^1(\mathbb{R}^+, X)$,

then it readily follows that the function

$$u(t) = S(t)x + \int_0^t S(t-s)f(s) ds$$

is an almost-orbit of $(S(t))_{t \geq 0}$. In particular, mild solutions of the inhomogeneous Cauchy problem

$$\begin{cases} \dot{u}(t) = Au(t) + f(t), & t > 0, \\ u(0) = x \in X \end{cases}$$

are almost-orbits of $(S(t))_{t \geq 0}$ whenever $f \in L^1(\mathbb{R}^+, X)$.

1.1.2. Assuming that X is uniformly convex and A is m -dissipative in X , if $f \in L^1(\mathbb{R}^+, X)$, then the integral solution (in the sense of B enilan [3]) to the Cauchy problem

$$\begin{cases} \dot{u}(t) \in Au(t) + f(t), & t > 0, \\ u(0) = x \in C \end{cases}$$

is an almost-orbit of the contraction semigroup $(S(t))_{t \geq 0}$ [19, p. 362].

The spaces of all bounded continuous functions from \mathbb{R}^+ into X and from \mathbb{R} into X will be denoted by $C_b(\mathbb{R}^+, X)$ and $C_b(\mathbb{R}, X)$, respectively, and we shall hereafter assume that each of these spaces is equipped with the supremum norm. For $J \in \{\mathbb{R}^+, \mathbb{R}\}$, $f \in C_b(J, X)$, and $\omega \in J$, moreover, we put $f_\omega(t) = f(t + \omega)$, $t \in J$, and let $H(f) = \{f_\omega : \omega \in J\}$ denote the set of all translates of f .

1.2. DEFINITION. (a) A function $f \in C_b(\mathbb{R}, X)$ is said to be *almost periodic* (a.p.) if $H(f)$ is relatively compact in $C_b(\mathbb{R}, X)$.

(b) A function $f \in C_b(\mathbb{R}^+, X)$ is said to be

(i) *asymptotically almost periodic* (a.a.p.) if $H(f)$ is relatively compact in $C_b(\mathbb{R}^+, X)$, and

(ii) *Eberlein-weakly almost periodic* (E.-w.a.p.) if $H(f)$ is weakly relatively compact in $C_b(\mathbb{R}^+, X)$.

Of these notions, (a) dates back to Bohl, Bohr, and Bochner (cf. [4]), (b) (i) to Fr chet [11, 12] for $\dim X < \infty$ (cf. [31] and [21, 22, 24] for general X), and (b) (ii) to Eberlein [9] in the scalar case (cf. [18] and [22, 25] for general X).

The spaces of all almost periodic, asymptotically almost periodic, and Eberlein-weakly almost periodic functions will be denoted by $AP(\mathbb{R}, X)$, $AAP(\mathbb{R}^+, X)$, and $W(\mathbb{R}^+, X)$, respectively. Further, we shall let $W_0(\mathbb{R}^+, X)$ denote the vector subspace of $W(\mathbb{R}^+, X)$ consisting of all $\varphi \in W(\mathbb{R}^+, X)$ for which the zero function belongs to

the weak closure of $H(\varphi)$, while $C_0(\mathbb{R}^+, X)$ will designate the set of those $\varphi \in C_b(\mathbb{R}^+, X)$ that vanish at infinity on \mathbb{R}^+ .

For future reference, we shall need the following basic facts concerning the notions of (almost) periodicity defined above.

1.3. THEOREM. *Let $u \in C_b(\mathbb{R}^+, X)$.*

(a) *The following are equivalent:*

(i) $u \in AAP(\mathbb{R}^+, X)$;

(ii) *there exist uniquely determined functions $g \in AP(\mathbb{R}, X)$ and $\varphi \in C_0(\mathbb{R}^+, X)$ such that $u = g|_{\mathbb{R}^+} + \varphi$.*

(b) *The following are equivalent:*

(i) $u \in W(\mathbb{R}^+, X)$;

(ii) *there exist uniquely determined functions $g \in AP(\mathbb{R}, X)$ and $\varphi \in W_0(\mathbb{R}^+, X)$ such that $u = g|_{\mathbb{R}^+} + \varphi$;*

(iii) *given any sequences $((t_m, x_m^*))_m$ in $\mathbb{R}^+ \times B_{X^*}$ and $(\omega_n)_n$ in \mathbb{R}^+ ,*

$$\lim_n \lim_m \langle u(t_m + \omega_n), x_m^* \rangle = \lim_m \lim_n \langle u(t_m + \omega_n), x_m^* \rangle$$

whenever both iterated limits exist.

Concerning 1.3(a), see Fréchet [11, 12], DeLeeuw and Glicksberg [7], and [22, 24]. The equivalence of (b) (i) and (b) (ii) follows from results in [7], while the equivalence of (b) (i) and (b) (iii) is established in [18] and [25].

In order to place the periodicity properties considered above in perspective—and to motivate the study of these notions in the context of operator semigroups—we make note of their relationship to commonly studied modes of asymptotic behavior for semigroup motions ((a), (d), and (e), below) before closing this preliminary section.

Let $u \in C_b(\mathbb{R}^+, X)$, and consider the following assertions:

(a) $\|\cdot\| - \lim_{t \rightarrow \infty} u(t)$ exists;

(b) $u \in AAP(\mathbb{R}^+, X)$;

(c) $u \in W(\mathbb{R}^+, X)$;

(d) $\|\cdot\| - \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T u(t) dt$ exists;

(e) $\gamma(u)$ is weakly relatively compact in X .

Then (a) implies (b), (b) implies (c), and (c) implies both (d) and (e).

The fact that (c) implies (d) is the extension of the classical ergodic theorem for scalar valued weakly almost periodic functions due to Eberlein [9] to the case of an arbitrary Banach range space given in [27] (also see [26]). The other implications are obvious.

2. Eberlein-weak almost periodicity for almost-orbits. Our presentation centers around two results. The first (Theorem 2.1) shows that Eberlein-weak almost periodicity arises quite naturally in the context of linear semigroups in that the only requirement for an almost-orbit u of a uniformly bounded C_0 -semigroup of linear operators on X to be E.-w.a.p. is that its orbit $\gamma(u)$ be weakly relatively compact in X . (A nonlinear counterpart of this result [26, Thm. 1.4] (also see [23, Théorème 1]) has been established for contraction semigroups in uniformly convex Banach spaces.) The second result (Theorem 2.4), which is valid for general (nonlinear) strongly continuous semigroups, provides a precise representation of E.-w.a.p. almost-orbits as “small” perturbations of (classical) almost periodic motions.

2.1. THEOREM. *Assume that $(S(t))_{t \geq 0}$ is a uniformly bounded C_0 -semigroup of continuous linear operators on X , and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$. Then u is Eberlein-weakly almost periodic if and only if $\gamma(u)$ is weakly relatively compact in X .*

2.2. COROLLARY. *If $(S(t))_{t \geq 0}$ is a uniformly bounded C_0 -semigroup of continuous linear operators on a reflexive Banach space X , then every almost-orbit of $(S(t))_{t \geq 0}$ is Eberlein-weakly almost periodic.*

Before turning to the proof of Theorem 2.1, some comments are in order.

2.3. REMARKS. 1. The assertion of Theorem 2.1 does not carry over to nonlinear operator semigroups, and even fails to hold in the case of contraction semigroups in Hilbert space. To see this, consider the example by Baillon [2] of a contraction semigroup $(S(t))_{t \geq 0}$ in l_2 generated by $-\partial\varphi$, where φ is a convex l.s.c. function such that $\partial\varphi^{-1}(0) \neq \emptyset$ and, for some $x \in \text{cl}\mathcal{D}(\varphi)$, $\|\cdot\|$ - $\lim_{t \rightarrow \infty} S(t)x$ does not exist. The motion $S(\cdot)x$ in this example is bounded, and thus has weakly relatively compact range, but $S(\cdot)x$ is not E.-w.a.p. Indeed, according to [27], if it were, then $\|\cdot\|$ - $\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T S(t)x \, dt$ would exist. However, Bruck [5, p. 25] has shown that

$$\lim_{T \rightarrow \infty} \left\| S(T)x - \frac{1}{T} \int_0^T S(t)x \, dt \right\| = 0$$

in the setting at hand, which would then yield the desired contradiction.

2. In the context of contraction semigroups on closed convex subsets

of uniformly convex Banach spaces, however, we have shown [26, Thm. 1.4] (also see [23, Théorème 1]) that a bounded almost-orbit u will be E.-w.a.p. provided that it is asymptotically isometric; i.e., if $\lim_{t \rightarrow \infty} \|u(t+h) - u(t)\| = \rho(h)$ exists uniformly over $h \in \mathbb{R}^+$.

3. The literature relating to weak almost periodicity properties of solutions to differential equations (e.g., see [1], [6], [17]) has heretofore dealt only with the notions of either a weakly almost periodic (w.a.p.) function $f \in C_b(\mathbb{R}, X)$ (i.e., $x^*f \in AP(\mathbb{R})$ for all $x^* \in X^*$) or a weakly asymptotically almost periodic (w.a.a.p.) function $f \in C_b(\mathbb{R}^+, X)$ (i.e., $x^*f \in AAP(\mathbb{R}^+)$ for all $x^* \in X^*$); we are not aware of any previous results pertaining to Eberlein-weak almost periodicity in the context of differential equations. Contrary to what might have been expected at the outset, however, Theorem 2.1 and [26, Thm. 1.4] cited above taken together with results from [27] and [28] indicate that Eberlein-weak almost periodicity occurs more naturally than weak asymptotic almost periodicity when it comes to motions and almost-orbits of operator semigroups, and can as well lead to stronger conclusions:

(a) In the case of a uniformly bounded linear C_0 -semigroup $(S(t))_{t \geq 0}$ on X , a motion through $x \in X$ is E.-w.a.p. provided only that its range $\gamma(x)$ is weakly relatively compact in X , whereas it is shown in [28] that $\gamma(x)$ must necessarily be relatively compact with respect to the (generally stronger) topology of uniform convergence on the sets $\{S(t)x^*: t \in \mathbb{R}^+\}$, $x^* \in X^*$, in order for $S(\cdot)x$ to be w.a.a.p. For an example where the two notions actually differ, let $X = W(\mathbb{R}^+)$ endowed with the sup-norm, and take $(S(t))_{t \geq 0}$ to be the restriction to X of the usual translation semigroup on the space $BUC(\mathbb{R}^+)$ of all bounded uniformly continuous functions on \mathbb{R}^+ . Then $\|S(t)\| \leq 1$ for every $t \in \mathbb{R}^+$, and every motion $S(\cdot)f: \mathbb{R}^+ \rightarrow X$ through $f \in W(\mathbb{R}^+)$ has weakly relatively compact range (by definition of $W(\mathbb{R}^+)$), whereby every motion is E.-w.a.p. by Theorem 2.1. However, each motion $S(\cdot)g: \mathbb{R}^+ \rightarrow X$ through some $g \in W(\mathbb{R}^+) \setminus AAP(\mathbb{R}^+)$ is obviously not w.a.a.p. Concrete examples of functions belonging to $W(\mathbb{R}^+) \setminus AAP(\mathbb{R}^+)$ are given in Examples 3.7 and 3.8 of [25].

(b) According to the ergodic theorem for E.-w.a.p. functions from [27], $\|\cdot\| - \lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T f(t+h) dt$ exists uniformly over $h \in \mathbb{R}^+$ whenever $f \in W(\mathbb{R}^+, X)$. Thus, Eberlein-weakly almost periodic functions behave as well as almost periodic functions with respect to convergence of ergodic means. For weakly (asymptotically) almost periodic functions, on the other hand, one can generally only conclude existence

of the ergodic limit in the weak topology (provided that X is weakly sequentially complete).

Proof of Theorem 2.1. Since an E.-w.a.p. function necessarily has weakly relatively compact range, we need only show that u is E.-w.a.p. when $\gamma(u)$ is weakly relatively compact. To this end, we assume that $\gamma(u)$ is weakly relatively compact in X and choose sequences $(\omega_n)_n$ in \mathbb{R}^+ and $((t_m, x_m^*))_m$ in $\mathbb{R}^+ \times B_{X^*}$ so that the limits

$$\alpha = \lim_n \lim_m \langle u(t_m + \omega_n), x_m^* \rangle \quad \text{and} \quad \beta = \lim_m \lim_n \langle u(t_m + \omega_n), x_m^* \rangle$$

both exist. According to Theorem 1.3, it will suffice to show that $\alpha = \beta$.

Case 1. $(\omega_n)_n$ is bounded.

We can thus assume that $\omega_n \rightarrow \omega \in \mathbb{R}^+$, whereby $(u_{\omega_n})_n$ converges uniformly on \mathbb{R}^+ to u_ω since u is uniformly continuous (cf. [19, p. 351]). From this, we conclude that $\beta = \lim_m \langle u_\omega(t_m), x_m^* \rangle$. Now, given $\varepsilon > 0$, choose $n_0 \in \mathbb{N}$ so that $\|u_{\omega_n}(t) - u_\omega(t)\| < \varepsilon$ for all $n \geq n_0$ and all $t \in \mathbb{R}^+$. Putting $\alpha_n = \lim_m \langle u(t_m + \omega_n), x_m^* \rangle$, $n \in \mathbb{N}$, we have that

$$|\alpha_n - \beta| = \lim_m |\langle u(t_m + \omega_n) - u_\omega(t), x_m^* \rangle| \leq \varepsilon$$

for all $n \geq n_0$ whence $\alpha = \lim_n \alpha_n = \beta$.

Case 2. $(\omega_n)_n$ is unbounded.

Here, we can assume that $\omega_n \rightarrow \infty$, as well as that $(u(\omega_n))_n$ is weakly convergent to some $x_0 \in X$ since $\gamma(u)$ is weakly relatively compact. For each $m \in \mathbb{N}$, since u is an almost-orbit of $(S(t))_{t \geq 0}$, we thus have that

$$\begin{aligned} \lim_n \langle u(t_m + \omega_n), x_m^* \rangle &= \lim_n (\langle u(t_m + \omega_n) - S(t_m)u(\omega_n), x_m^* \rangle + \langle S(t_m)u(\omega_n), x_m^* \rangle) \\ &= \langle S(t_m)x_0, x_m^* \rangle, \end{aligned}$$

and hence $\beta = \lim_m \langle S(t_m)x_0, x_m^* \rangle$. Further, since $(S(t_m)^*x_m^*)_m$ is a bounded sequence in X^* , there exist $x_0^* \in X^*$ and a subnet $(S(t_{m_\lambda})^*x_{m_\lambda}^*)_\lambda$ of $(S(t_m)^*x_m^*)_m$ which is w^* -convergent to x_0^* . Now, given $\varepsilon > 0$, choose $n_0 \in \mathbb{N}$ so that

- (i) $|\langle u(\omega_n) - x_0, x_0^* \rangle| < \varepsilon/2$ when $n \geq n_0$ and
- (ii) $\|u(t + \omega_n) - S(t)u(\omega_n)\| < \varepsilon/2$ for any $n \geq n_0$ and all $t \in \mathbb{R}^+$.

Again setting $\alpha_n = \lim_m \langle u(t_m + \omega_n), x_m^* \rangle$ for $n \in \mathbb{N}$, if $n \geq n_0$, we then have that

$$\begin{aligned} |\alpha_n - \beta| &= \lim_{\lambda} |\langle u(t_{m_\lambda} + \omega_n) - S(t_{m_\lambda})x_0, x_{m_\lambda}^* \rangle| \\ &\leq \lim_{\lambda} |\langle u(t_{m_\lambda} + \omega_n) - S(t_{m_\lambda})u(\omega_n), x_{m_\lambda}^* \rangle| \\ &\quad + \lim_{\lambda} |\langle S(t_{m_\lambda})u(\omega_n) - S(t_{m_\lambda})x_0, x_{m_\lambda}^* \rangle| \\ &\leq \varepsilon/2 + |\langle u(\omega_n) - x_0, x_0^* \rangle| < \varepsilon. \end{aligned}$$

Having thus shown that $\alpha = \beta$ in this case as well, the proof of Theorem 2.1 is complete.

In what follows, we shall say that a function $f \in C_b(\mathbb{R}^+, X)$ is almost periodic if f is the restriction to \mathbb{R}^+ of an almost periodic function $g \in AP(\mathbb{R}, X)$.

2.4. THEOREM. *Assume that $(S(t))_{t \geq 0}$ is a strongly continuous semi-group of operators on a weakly closed subset C of X , and let $u: \mathbb{R}^+ \rightarrow C$ be an almost-orbit of $(S(t))_{t \geq 0}$ such that*

() $S(h)|w\text{-cl } \gamma(u): w\text{-cl } \gamma(u) \rightarrow X$ is weak-to-weak continuous for each $h \in \mathbb{R}^+$.*

Then $u \in W(\mathbb{R}^+, X)$ if and only if there exist unique elements $y \in \omega_w(u)$ and $\varphi \in W_0(\mathbb{R}^+, X)$ such that

- (i) $u = S(\cdot)y + \varphi$, and*
- (ii) $S(\cdot)y$ is almost periodic.*

In other words, an almost-orbit u of $(S(t))_{t \geq 0}$ for which (*) holds is E.-w.a.p. if and only if u is a perturbation of an *almost periodic motion* of $(S(t))_{t \geq 0}$ by a function in $W_0(\mathbb{R}^+, X)$. Before proving this, we pause to make some further observations.

2.5. REMARKS. 1. Condition (*) in Theorem 2.4 could be replaced by the following formally weaker assumption:

()** For any sequence $0 \leq t_n \rightarrow \infty$, if $(u(t_n))_n$ is weakly convergent to some $y \in C$, then $(S(h)u(t_n))_n$ converges weakly to $S(h)y$ for every $h \in \mathbb{R}^+$.

In fact, as the following technical lemma shows, conditions (*) and (**) are actually equivalent under the circumstances at hand.

LEMMA. *Assume that C is a weakly closed subset of X , $S: C \rightarrow X$ is continuous, and $u: \mathbb{R}^+ \rightarrow C$ is a continuous function with weakly*

relatively compact range. Moreover, assume that

(#) *for any sequence $0 \leq t_n \rightarrow \infty$, if $(u(t_n))_n$ converges weakly to some $y \in C$, then $(Su(t_n))_n$ converges weakly to Sy .*

Then $S|_{\text{w-cl } \gamma(u)}: \text{w-cl } \gamma(u) \rightarrow X$ is weak-to-weak continuous.

Starting from the fact that weakly compact subsets of separable Banach spaces are weakly metrizable (cf. [8, p. 434]), a proof of this lemma follows along elementary lines.

2. Clearly, condition (*) of Theorem 2.4 is always satisfied by a linear C_0 -semigroup $(S(t))_{t \geq 0}$ on X and any almost-orbit u of $(S(t))_{t \geq 0}$. According to [10, Thm. 3.1], and taking the foregoing lemma into account, (*) is likewise satisfied by a (nonlinear) contraction semigroup $(S(t))_{t \geq 0}$ on a reflexive Banach space X and any bounded almost-orbit u provided that $(S(t))_{t \geq 0}$ has an everywhere defined weakly sequentially continuous generator. In view of Remark 2.5.1 and [26, Lemma 1.7], moreover, (*) holds for any contraction semigroup $(S(t))_{t \geq 0}$ on a closed convex subset C of a uniformly convex Banach space X in case u is a bounded almost-orbit that is asymptotically isometric (i.e., such that $\lim_{t \rightarrow \infty} \|u(t+h) - u(t)\| = \rho(h)$ exists uniformly over $h \in \mathbb{R}^+$). This latter situation arises in various settings (e.g., see [19, Prop. 5.5 and Cor. 6.2] and [15, §9.3]); we here note only the following one: If X is a Hilbert space, $(S(t))_{t \geq 0}$ is a contraction semigroup on a closed convex subset C of X , $0 \in C$, and there exists a constant $L \geq 0$ such that

$$\|S(t)x + S(t)y\|^2 \leq \|x + y\|^2 + L(\|x\|^2 - \|S(t)x\|^2 + \|y\|^2 - \|S(t)y\|^2)$$

for all $t \in \mathbb{R}^+$ and $x, y \in C$, then every almost-orbit u of $(S(t))_{t \geq 0}$ is asymptotically isometric [19, p. 361]. In particular, the above estimate holds (for $L = 0$) if $C = -C$ and $(S(t))_{t \geq 0}$ is odd (i.e., $S(t)(-x) = -S(t)x$ for all $t \in \mathbb{R}^+$ and all $x \in C$).

3. For a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of bounded linear operators on X , Theorems 2.1 and 2.4 together show that any motion $S(\cdot)x$ with weakly relatively compact range is Eberlein-weakly almost periodic and uniquely decomposes into the sum $S(\cdot)x = S(\cdot)y + \varphi$ of an almost periodic motion $S(\cdot)y$ and a motion $\varphi = S(\cdot)(x - y)$ belonging to $W_0(\mathbb{R}^+, X)$. We wish to point out that direct application of the DeLeeuw-Glicksberg theory [7, Thm. 4.11] to the semigroup $(S(t))_{t \geq 0}$ only yields a decomposition of the form $S(\cdot)x = S(\cdot)x_r + S(\cdot)x_0$ where $S(\cdot)x_r$ is almost periodic and $S(\cdot)x_0$ is such that $0 \in \text{w-cl } \gamma(x_0)$. Consequently, even when attention is restricted

to motions, Theorem 2.1 provides an improvement over direct application of the DeLeeuw-Glicksberg theory through the additional information that the motion $S(\cdot)x_0$ —and thus $S(\cdot)x$ itself—is actually E.-w.a.p.

Proof of Theorem 2.4. Since the decomposition specified in Theorem 2.4 is certainly sufficient to guarantee that $u \in W(\mathbb{R}^+, X)$, we need only show that it is also necessary, and so let us assume that the almost-orbit u is E.-w.a.p. By Theorem 1.3, therefore, there exist uniquely determined functions $g \in AP(\mathbb{R}, X)$ and $\varphi \in W_0(\mathbb{R}^+, X)$ such that

$$(1) \quad u = g|_{\mathbb{R}^+} + \varphi.$$

As $\varphi \in W_0(\mathbb{R}^+, X)$, there exists a sequence $0 \leq \omega_n \rightarrow \infty$ such that

$$(2) \quad (\varphi_{\omega_n})_n \text{ converges weakly in } C_b(\mathbb{R}^+, X) \text{ to the zero function.}$$

Moreover, we can assume that

$$(3) \quad (u(\omega_n))_n \text{ is weakly convergent to some } z \in \omega_w(u), \text{ and}$$

$$(4) \quad (g_{\omega_n})_n \text{ converges uniformly on } \mathbb{R} \text{ to some } f \in AP(\mathbb{R}, X).$$

For each $\varepsilon > 0$, since $g \in AP(\mathbb{R}, X)$, there exists a relatively dense subset $P_\varepsilon(g)$ of \mathbb{R} such that $\|g(t+\tau) - g(t)\| < \varepsilon$ for each $\tau \in P_\varepsilon(g)$ and all $t \in \mathbb{R}$ [4]. Thus, choosing $\tau_n \in [2\omega_n, \infty) \cap P_{1/n}(g)$, $n \in \mathbb{N}$, it is easy to see that

$$(5) \quad (g_{\tau_n})_n \text{ converges to } g \text{ uniformly on } \mathbb{R}.$$

For each $t \in \mathbb{R}^+$, taking (*) and the fact that u is an almost-orbit of $(S(t))_{t \geq 0}$ into account, we also have that $(S(t)u(\omega_n))_n$ converges weakly to $S(t)z$ and $\lim_n \|u(t + \omega_n) - S(t)u(\omega_n)\| = 0$. Combining these observations with (1), (2), and (4), we conclude that

$$(6) \quad f(t) = S(t)z \text{ for each } t \in \mathbb{R}^+.$$

We now claim that

$$(7) \quad (f_{\tau_n - \omega_n})_n \text{ converges uniformly on } \mathbb{R} \text{ to } g.$$

Indeed, given $\varepsilon > 0$, choose $n_0 \in \mathbb{N}$ so that $\|g_{\omega_n}(t) - f(t)\| < \varepsilon/2$ and $\|g_{\tau_n}(t) - g(t)\| < \varepsilon/2$ for all $t \in \mathbb{R}$ and every $n \geq n_0$. Then

$$\begin{aligned} & \|g(t) - f_{\tau_n - \omega_n}(t)\| \\ & \leq \|g(t) - g_{\tau_n}(t)\| + \|g_{\omega_n}(t + \tau_n - \omega_n) - f(t + \tau_n - \omega_n)\| < \varepsilon \end{aligned}$$

for all $t \in \mathbb{R}$ and every $n \geq n_0$.

At this point, setting $y_n = S(\tau_n - \omega_n)z$, $n \in \mathbb{N}$, it follows from (6) and (7) that

$$(8) \quad \|\cdot\| - \lim_n y_n = g(0).$$

For each $n \in \mathbb{N}$, moreover, again using (*) and the fact that u is an almost-orbit of $(S(t))_{t \geq 0}$,

$$y_n = \text{w-}\lim_m S(\tau_n - \omega_n)u(\omega_m) = \text{w-}\lim_m u(\omega_m + \tau_n - \omega_n) \in \omega_w(u).$$

As we note in the following technical lemma, however, $\omega_w(u)$ is weakly closed, and hence

$$(9) \quad y = g(0) \in \omega_w(u).$$

Finally, according to (6), (7), and (9), we have that

$$S(t)y = \|\cdot\|-\lim_n S(t)y_n = \|\cdot\|-\lim_n f_{\tau_n - \omega_n}(t) = g(t)$$

for each $t \in \mathbb{R}^+$, which completes the proof of Theorem 2.4.

2.6. LEMMA. *If $u: \mathbb{R}^+ \rightarrow X$ is weakly continuous and $u(\mathbb{R}^+)$ is weakly relatively compact in X , then $\omega_w(u)$ is weakly compact.*

Proof. Since there is no loss of generality in replacing X by $\text{cl}(\text{span}(u(\mathbb{R}^+)))$, we may assume that X is separable. Thus, since $K = \text{w-cl } u(\mathbb{R}^+)$ is weakly compact, K is weakly metrizable [8, p. 434]. As $\omega_w(u) \subseteq K$, it would therefore suffice to show that $\omega_w(u)$ is closed in (K, d) , where d is a metric on K that induces the relative weak topology $\sigma(X, X^*)|_K$, but this is obvious.

REMARK. Lemma 2.6 leads to the following extension of a result by Slemrod [29, Lemma 2.1] for weak (semi)dynamical systems on separable reflexive Banach spaces.

2.7. PROPOSITION. *Assume that $\pi: \mathbb{R}^+ \times X \rightarrow X$ is a weak dynamical system on the Banach space X , and that, for some $x \in X$, $\gamma(x)$ is weakly relatively compact in X . Then $\omega_w(x)$ is nonvoid, weakly compact, and invariant.*

3. Applications and related results. In view of the connection between solutions of abstract Cauchy problems associated with a generator A of a strongly continuous semigroup $(S(t))_{t \geq 0}$ of operators and motions or almost-orbits of $(S(t))_{t \geq 0}$, the assertions of Theorems 2.1 and 2.4 can thus be used to

- (1) determine whether such solutions are Eberlein-weakly almost periodic,

and thereby to

- (2) obtain existence of (classical) almost periodic solutions even in the absence of *a priori* norm-compactness assumptions,

and

- (3) establish the existence of the norm-limit of ergodic means for solutions.

We will begin by illustrating these features, and shall here focus on

the linear case; the case of abstract Cauchy problems associated with m -dissipative (generally multivalued) operators in uniformly convex Banach spaces (see Remark 2.5.2) has been treated in detail in [26].

Throughout the remainder of the section, we assume that $A: \mathcal{D}(A) \subseteq X \rightarrow X$ is the infinitesimal generator of a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of continuous linear operators on X . We shall further consider both the homogeneous Cauchy problem

$$(\text{CP}_h) \quad \begin{cases} \dot{u}(t) = Au(t), & t > 0, \\ u(0) = x_0 \end{cases}$$

with initial data $x_0 \in X$ and, for a given function $f \in L^1(\mathbb{R}^+, X)$, the inhomogeneous Cauchy problem

$$(\text{CP}) \quad \begin{cases} \dot{u}(t) = Au(t) + f(t), & t > 0, \\ u(0) = x_0 \end{cases}$$

associated with A .

It is well known (cf. [13], [20]) that $u = S(\cdot)x_0$ is the (unique) strong solution of (CP_h) in case $x_0 \in \mathcal{D}(A)$, and that the mild solution $u(t) = S(t)x_0 + \int_0^t S(t-s)f(s)ds$ of (CP) is the candidate for a (classical) solution. As noted in 1.1.1, moreover, every mild solution of (CP) (i.e., the mild solution corresponding to any $x_0 \in X$) is an almost-orbit of $(S(t))_{t \geq 0}$.

3.1. THEOREM. 1. *If (CP_h) has a strong solution u with weakly relatively compact range, then $u = S(\cdot)x_0$ is Eberlein-weakly almost periodic and has a (unique) decomposition $u = S(\cdot)y + \varphi$, where $\varphi \in W_0(\mathbb{R}^+, X)$ and $y \in \omega_w(x_0)$ is such that $S(\cdot)y$ is almost periodic.*

2. *If the mild solution u of (CP) has weakly relatively compact range, then u is Eberlein-weakly almost periodic and has a (unique) decomposition $u = S(\cdot)y + \varphi$, where $\varphi \in W_0(\mathbb{R}^+, X)$ and $y \in \omega_w(u)$ is such that $S(\cdot)y$ is almost periodic.*

3.2. COROLLARY. 1. *Assume that X is reflexive. Then*

(a) *every strong solution of (CP_h) is Eberlein-weakly almost periodic;*

(b) *if $x_0 \in \mathcal{D}(A)$, then there exist $y \in \omega_w(x_0) \cap \mathcal{D}(A)$ such that the strong solution $u = S(\cdot)y$ of (CP_h) for the initial condition $u(0) = y$ is almost periodic;*

(c) *every mild solution of (CP) is Eberlein-weakly almost periodic.*

2. *If $(S(t))_{t \geq 0}$ is a differentiable semigroup and $u: \mathbb{R}^+ \rightarrow X$ is any strong solution of (CP_h) with weakly relatively compact range, then*

there exists $y \in \omega_w(u)$ such that $S(\cdot)y: \mathbb{R}^+ \rightarrow X$ is an almost periodic strong solution of (CP_h) (with initial vector $x_0 = y$).

As Corollary 3.2 makes plain, Theorem 3.1 can be used to deduce existence of almost periodic strong solutions of (CP_h) without *a priori* norm-compactness assumptions. We mention that every strong solution of (CP_h) with norm-relatively compact range is asymptotically almost periodic [21, Corollary 2.5], which also leads to the existence of almost periodic strong solutions to (CP_h) in view of the decomposition of an a.a.p motion of $(S(t))_{t \geq 0}$ [21, p. 150] as the sum of an a.p. motion and a function belonging to $C_0(\mathbb{R}^+, X)$.

We now turn to the question of convergence of ergodic means. Instead of just considering the limit of the Cesaro means $\frac{1}{T} \int_0^T u(t) dt$ of a solution u to either (CP_h) or (CP) , moreover, we shall take into account means with respect to any strongly regular kernel; a function $Q: \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow \mathbb{R}$ is said to be *strongly regular* if

- (i) $\{Q(s, \cdot) : s \in \mathbb{R}^+\}$ is a bounded subset of $L^1(\mathbb{R}^+)$,
- (ii) $\lim_{s \rightarrow \infty} \int_0^\infty Q(s, t) dt = 1$,
- (iii) $\lim_{s \rightarrow \infty} \int_0^T |Q(s, t)| dt = 0$ for each $T > 0$, and
- (iv) $\lim_{s \rightarrow \infty} \int_0^\infty |Q(s, t+h) - Q(s, t)| dt = 0$ for all $h \in \mathbb{R}^+$.

3.3. THEOREM. Assume that $(S(t))_{t \geq 0}$ is a uniformly bounded C_0 -semigroup of continuous linear operators on X , and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$ with weakly relatively compact range. Then there exists $z \in \text{clco } \omega_w(u)$ such that

$$\|\cdot\| \cdot \lim_{s \rightarrow \infty} \int_0^\infty Q(s, t) u(t+h) dt = z$$

uniformly over $h \in \mathbb{R}^+$ for any strongly regular kernel function $Q: \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow \mathbb{R}$. Moreover, z is a fixed point of $(S(t))_{t \geq 0}$, and the only such in $\text{clco } \omega_w(u)$.

Theorem 3.3 is a consequence of Theorem 2.1 taken in conjunction with the strong ergodic theorem for Eberlein-weakly almost periodic functions from [27]. In the special case that u is a motion $S(\cdot)x$ of $(S(t))_{t \geq 0}$ through some $x \in X$, Theorem 3.3 becomes a version for individual motions of the well known mean ergodic theorem for uniformly bounded C_0 -semigroups on reflexive Banach spaces (cf. [13]).

3.4. COROLLARY. Assume that $u: \mathbb{R}^+ \rightarrow X$ is either a strong solution of (CP_h) or a mild solution of (CP) . If u has weakly relatively

compact range, then there exists a unique fixed point z of $(S(t))_{t \geq 0}$ in $\text{cl co } \omega_\omega(u)$ such that

$$\|\cdot\|-\lim_{s \rightarrow \infty} \int_0^\infty Q(s, t) u(t+h) dt = z$$

uniformly over $h \in \mathbb{R}^+$ for any strongly regular kernel function $Q: \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow \mathbb{R}$.

Before taking up further specific applications, we pause to recall the following fact (cf. [19, p. 350]): For $f \in C_b(\mathbb{R}^+, X)$ and $x \in X$, if

(i) $f - f_\omega \in C_0(\mathbb{R}^+, X)$ (respectively, $f - f_\omega$ weakly vanishes at infinity on \mathbb{R}^+) for each $\omega \geq 0$, and

(ii)

$$\|\cdot\|-\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T f(s+h) ds = x$$

$$\left(\text{respectively, } w\text{-}\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T f(s+h) ds = x \right)$$

uniformly over $h \in \mathbb{R}^+$, then

$$\|\cdot\|-\lim_{t \rightarrow \infty} f(t) = x \quad \left(\text{respectively, } w\text{-}\lim_{t \rightarrow \infty} f(t) = x \right).$$

Taken together with Theorem 3.3, this leads to the following result.

3.5. COROLLARY. *Assume that $(S(t))_{t \geq 0}$ is a uniformly bounded C_0 -semigroup of continuous linear operators on X , and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$ with weakly relatively compact range. If $\lim_{t \rightarrow \infty} \|u(t+h) - u(t)\| = 0$ (respectively, $w\text{-}\lim_{t \rightarrow \infty} (u(t+h) - u(t)) = 0$) for each $h \in \mathbb{R}^+$, then $\|\cdot\|-\lim_{t \rightarrow \infty} u(t)$ (respectively, $w\text{-}\lim_{t \rightarrow \infty} u(t)$) exists and equals $\|\cdot\|-\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T u(t) dt$.*

In case the uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ generated by A is the restriction to \mathbb{R}^+ of an analytic semigroup of type (α, M) [13, p. 33], $\|tAS(t)x\| \leq M\|x\|$ for each $t > 0$ and every $x \in X$, whereby it easily follows that, given any $x \in X$,

$$\lim_{t \rightarrow \infty} \|S(t+h)x - S(t)x\| = 0$$

for each $h \in \mathbb{R}^+$. Since the restriction to \mathbb{R}^+ of any analytic semigroup of type (α, M) is necessarily uniformly bounded, this observation coupled with [19, Prop. 6.3, p. 361] and Corollary 3.5 yields the

next assertion, which includes a version for individual motions of a known result for analytic semigroups on reflexive Banach spaces (cf. [13, Exercise 17, p. 61]).

3.6. COROLLARY. *Assume that $(S(t))_{t \geq 0}$ is a C_0 -semigroup of bounded linear operators on X which is the restriction to \mathbb{R}^+ of an analytic semigroup of type (α, M) , and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$. If $u(\mathbb{R}^+)$ is weakly relatively compact in X , then $\|\cdot\|-\lim_{t \rightarrow \infty} u(t)$ exists and equals $\|\cdot\|-\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T u(t) dt$.*

Concerning stability properties of the C_0 -semigroup $(S(t))_{t \geq 0}$ generated by A , additional information about the point spectrum $\sigma_p(A)$ of A leads to the following result.

3.7. PROPOSITION. *Assume that A is the infinitesimal generator of a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of continuous linear operators on X , and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$ with weakly relatively compact range. If $\sigma_p(A) \cap i\mathbb{R} = \emptyset$, then $u \in W_0(\mathbb{R}^+, X)$. In particular, $\|\cdot\|-\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T u(t+h) dt = 0$ uniformly over $h \in \mathbb{R}^+$ whenever $\sigma_p(A) \cap i\mathbb{R} = \emptyset$.*

REMARK. For the connection between Proposition 3.7 and stability of $(S(t))_{t \geq 0}$, recall that $(S(t))_{t \geq 0}$ is said to be strongly (respectively, weakly) stable if $\|\cdot\|-\lim_{t \rightarrow \infty} S(t)x = 0$ (respectively, $w\text{-}\lim_{t \rightarrow \infty} S(t)x = 0$) for each $x \in X$. This, in turn, is equivalent to requiring that, given any $x \in X$, there exists a sequence $0 \leq \omega_n \rightarrow \infty$ such that the corresponding sequence $(S(\cdot + \omega_n)x)_n$ of translates converges to the zero function in $C_b(\mathbb{R}^+, X)$ (respectively, uniformly in $C_b(\mathbb{R}^+, X_w)$, where X_w denotes X with its associated weak topology $\sigma(X, X^*)$). According to Proposition 3.7, if $\sigma_p(A) \cap i\mathbb{R} = \emptyset$ and u is any almost-orbit of $(S(t))_{t \geq 0}$ with weakly relatively compact range, then there does exist a sequence $0 \leq \omega_n \rightarrow \infty$ such that $(u_{\omega_n})_n$ converges to the zero function with respect to the weak topology of $C_b(\mathbb{R}^+, X)$. Of course, the condition $\sigma_p(A) \cap i\mathbb{R} = \emptyset$ is necessary for the weak stability of $(S(t))_{t \geq 0}$.

Proof of Proposition 3.7. From Theorems 2.1 and 2.4, we know that $u = S(\cdot)y + \varphi$, where $\varphi \in W_0(\mathbb{R}^+, X)$ and $y \in \omega_w(u)$ is such that $S(\cdot)y$ is almost periodic. For $\mu \in \mathbb{R}$, let

$$a(y, \mu) = \|\cdot\|-\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T e^{-i\mu t} S(t)y dt$$

be the corresponding Fourier coefficient of (the almost periodic function) $S(\cdot)y$. It is then easy to check that $e^{-i\mu t}S(t)a(y, \mu) = a(y, \mu)$ for all $t \in \mathbb{R}^+$, and hence $a(y, \mu) = 0$ in view of the assumption on $\sigma_p(A)$. Since $a(y, \mu) = 0$ for each $\mu \in \mathbb{R}$, $S(t)y = 0$ for every $t \in \mathbb{R}^+$, and thus $u \in W_0(\mathbb{R}^+, X)$. Since this implies that $0 \in \omega_w(u)$, the final assertion now follows as an immediate consequence of Theorem 3.3.

3.8. COROLLARY. *Assume that X is reflexive, and let A be the infinitesimal generator of a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of continuous linear operators on X . Then the following are equivalent:*

- (a) $\sigma_p(A) \cap i\mathbb{R} = \emptyset$;
- (b) every almost-orbit of $(S(t))_{t \geq 0}$ belongs to $W_0(\mathbb{R}, X)$;
- (c) $S(\cdot)x \in W_0(\mathbb{R}^+, X)$ for each $x \in X$;
- (d) $\liminf_{t \rightarrow \infty} |\langle S(t)x, x^* \rangle| = 0$ for each $x \in X$ and all $x^* \in X^*$.

Corollary 3.8 includes [14, Thm. 2] as a special case. In much the same way, our approach also yields a short proof (of an extension) of [14, Thm. 1].

3.9. COROLLARY. *Assume that A is the infinitesimal generator of a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of continuous linear operators on X such that $\sigma_p(A) \cap i\mathbb{R} = \emptyset$ and let $u: \mathbb{R}^+ \rightarrow X$ be an almost-orbit of $(S(t))_{t \geq 0}$ with weakly relatively compact range. If $x^*u \in AAP(\mathbb{R}^+)$ for some $x^* \in X^*$, then $x^*u \in C_0(\mathbb{R}^+)$.*

Proof. According to Theorem 1.3, we have that $x^*u = g|_{\mathbb{R}^+} + \varphi$, where $g \in AP(\mathbb{R})$ and $\varphi \in C_0(\mathbb{R}^+)$, while $x^*u \in W_0(\mathbb{R}^+)$ in view of Proposition 3.7. Consequently, there exists a sequence $0 \leq \omega_n \rightarrow \infty$ so that $((x^*u - \varphi)_{\omega_n})_n$ converges pointwise on \mathbb{R}^+ to the zero function. A routine argument based on the fact that $g \in AP(\mathbb{R})$ now shows that g is identically zero, whereby the proof is complete.

Our final set of applications concerns an abstract version of the principle of local energy decay for solutions of the wave equation in exterior domains as considered in [16, Chap. V], [30], and [14]. More specifically, we give a short and straightforward treatment of (an extension of) the material presented in [14, Section 1.2].

To set the context for these results, we assume that X is a reflexive Banach space, and take F to be a Fréchet space (i.e., a complete

metrizable locally convex space) in which X is continuously embedded. (In applications, for instance, $X = L^2(\Omega)$ and $F = L^2_{\text{loc}}(\Omega)$.) Furthermore, $A: \mathcal{D}(A) \subset X \rightarrow X$ will be the infinitesimal generator of a uniformly bounded C_0 -semigroup $(S(t))_{t \geq 0}$ of continuous linear operators on X .

3.10. PROPOSITION. *Assume that $\sigma_p(A) \cap i\mathbb{R} = \emptyset$. Then*

$$F\text{-}\lim_{t \rightarrow \infty} S(t)x = 0$$

for each $x \in X$ such that $H(S(\cdot)x) = \{S(\cdot + \omega): \omega \in \mathbb{R}^+\}$ is relatively compact in $C_b(\mathbb{R}^+, F)$ with respect to the topology of uniform convergence.

Proof. Fixing $x \in X$ so that $H(S(\cdot)x)$ is relatively compact in $C_b(\mathbb{R}^+, F)$ with respect to the topology of uniform convergence, it then follows that $S(\cdot)x = g|_{\mathbb{R}^+} + \varphi$, where $g \in AP(\mathbb{R}, F)$ and $\varphi \in C_0(\mathbb{R}^+, F)$ [21, p. 147]. By Corollary 3.8, moreover, $S(\cdot)x \in W_0(\mathbb{R}^+, X)$. Thus, since $g|_{\mathbb{R}^+} = S(\cdot)x - \varphi$, we again have that $g|_{\mathbb{R}^+}$ is identically zero, and the proof is thereby complete.

3.11. PROPOSITION. *Assume that $\sigma_p(A) \cap i\mathbb{R} = \emptyset$, and let $x \in X$. If $\gamma(x)$ is relatively compact in F , then there exists a sequence $0 \leq \omega_n \rightarrow \infty$ such that the corresponding sequence $(S(\cdot + \omega_n)x)_n$ of translates of $S(\cdot)x$ converges to zero in $C_b(\mathbb{R}^+, F)$ with respect to the topology of uniform convergence on the compact subsets of \mathbb{R}^+ .*

Proof. Given $x \in X$, and again applying Corollary 3.8, $\varphi = S(\cdot)x \in W_0(\mathbb{R}^+, X)$, and so there exists a sequence $0 \leq \omega_n \rightarrow \infty$ such that $(\varphi_{\omega_n})_n$ converges to the zero function with respect to the weak topology of $C_b(\mathbb{R}^+, X)$. Assuming that $\gamma(x)$ is relatively compact in F , therefore, we may further suppose that $(S(t + \omega_n)x)_n$ converges to zero in F for each $t \in \mathbb{R}^+$. Since $S(\cdot)x: \mathbb{R}^+ \rightarrow F$ is also uniformly continuous, the desired conclusion now follows readily.

REMARK. Propositions 3.10 and 3.11 extend Theorems 3 and 4 of [14].

In closing, we mention that analogues of our results for semigroups can be deduced for groups of operators through the same techniques, and we state one particular result.

3.12. THEOREM. *Assume that $(G(t))_{t \in \mathbb{R}}$ is a uniformly bounded C_0 -group of continuous linear operators on a Banach space X , and let $x \in X$. Then $G(\cdot)x \in W(\mathbb{R}, X)$ if and only if $G(\cdot)x$ has weakly relatively compact range in X . In this case, $G(\cdot)x = G(\cdot)y + \varphi$, where $\varphi \in W_0(\mathbb{R}, X)$ and $y \in \omega_w(X)$ with $G(\cdot)y \in AP(\mathbb{R}, X)$.*
