ON THE ANALYTIC REFLECTION OF A MINIMAL SURFACE

JAIGYOUNG CHOE

ON THE ANALYTIC REFLECTION OF A MINIMAL SURFACE

JAIGYOUNG CHOE

For a long time it has been known that in a Euclidean space one can reflect a minimal surface across a part of its boundary if the boundary contains a line segment, or if the minimal surface meets a plane orthogonally along the boundary. The proof of this fact makes use of H. A. Schwarz's reflection principle for harmonic functions.

In this paper we show that a minimal surface, as a conformal and harmonic map from a Riemann surface into \mathbf{R}^3 , can also be reflected analytically if it meets a plane at a constant angle.

THEOREM 1. *Let $\Sigma \subset \mathbf{R}^3$ be a minimal surface with nonempty boundary $\partial\Sigma$ and let Π be a plane. Suppose that $L \subset \Sigma \cap \Pi$ is a C^1 curve, Σ is C^1 along L , and at all points of L the tangent plane to Σ makes a fixed angle $0 < \theta < 90^\circ$ with Π . Then Σ can be analytically extended across L to a minimal surface $\bar{\Sigma}$ satisfying the following properties:*

(i) $\bar{\Sigma} = \Sigma \cup \Sigma^*$, where Σ^* is the set of all images p^* of $p \in \Sigma$ under an analytic reflection map $*$.

(ii) p and p^* are separated by Π in such a way that

$$\text{dist}(p, \Pi) = \text{dist}(p^*, \Pi).$$

(iii) The Gauss map $g: \bar{\Sigma} \rightarrow \mathbf{C}$ satisfies

$$\overline{g(p)} \cdot g(p^*) = \left(\tan \frac{\theta}{2} \right)^{-2}.$$

(iv) $p^* \in \Sigma^*$ is a branch point (geometric) if and only if $p \in \Sigma$ is.

(v) The map $*$ is a single-valued immersion if Σ is simply connected and L is connected, or Σ is doubly connected and L is closed.

(vi) If $*$ is single-valued, then Σ^* has finite total curvature if and only if Σ does.

(vii) If $\partial\Sigma = L$, then $\bar{\Sigma}$ is complete.

Proof. Let x, y, z be coordinates of \mathbf{R}^3 such that $\Pi = \{(x, y, z): z = 0\}$. Since x, y, z are harmonic functions on the minimal surface Σ , one can find conjugate harmonic (possibly multiple-valued)

functions $\bar{x}, \bar{y}, \bar{z}$ to x, y, z respectively on Σ . Then

$$u = x + i\bar{x}, \quad v = y + i\bar{y}, \quad w = z + i\bar{z}$$

are holomorphic (possibly multiple-valued) functions on Σ , and

$$du = dx + id\bar{x}, \quad dv = dy + id\bar{y}, \quad dw = dz + id\bar{z}$$

are holomorphic 1-forms on Σ . Introduce z, \bar{z} as conformal parameters on Σ . Then Σ can be recaptured by setting

$$x = \operatorname{Re} \int^w du, \quad y = \operatorname{Re} \int^w dv, \quad z = \operatorname{Re} \int^w dw.$$

From the conjugacy of $\bar{x}, \bar{y}, \bar{z}$ to x, y, z , it follows that

$$du^2 + dv^2 + dw^2 = 0.$$

Define a holomorphic differential ω and a meromorphic function g on Σ by

$$\omega = du - idv, \quad g = \frac{dw}{du - idv}.$$

Then we have

$$(1) \quad \begin{aligned} x &= \operatorname{Re} \int^w \frac{1}{2} \left(-g + \frac{1}{g} \right) dw, \\ y &= \operatorname{Re} \int^w \frac{i}{2} \left(g + \frac{1}{g} \right) dw, \\ z &= \operatorname{Re} \int^w dw. \end{aligned}$$

It is well known that g is exactly the Gauss map of the surface Σ .

Put $-\Sigma = \{(x, y, -z) : (x, y, z) \in \Sigma\}$ and define a Riemann surface $\tilde{\Sigma}$ by $\tilde{\Sigma} = \Sigma \cup (-\Sigma)$. For any $p = (x, y, z) \in \Sigma$, let $-p = (x, y, -z) \in -\Sigma$. Since $z = 0$ on $\Sigma \cap (-\Sigma) (\supset L)$, we can extend the conformal parameters z, \bar{z} over to $\tilde{\Sigma}$ (across L) by the usual reflection with respect to Π , that is,

$$z(-p) = -z(p) \quad \text{and} \quad \bar{z}(-p) = \bar{z}(p) \quad \text{for any } -p \in -\Sigma.$$

Hence we see that dw is a well-defined holomorphic 1-form on the Riemann surface $\tilde{\Sigma}$.

Now note that the constant angle hypothesis implies

$$|g(p)| = \left(\tan \frac{\theta}{2} \right)^{-1} \quad \text{for all } p \in L.$$

In other words, g maps L into a circle in \mathbf{C} . Since Σ is C^1 along L and L plays the same role in the Riemann surface $\tilde{\Sigma}$ as a line does

in \mathbf{C} , we can extend the Gauss map g holomorphically over to $\tilde{\Sigma}$ (across L) as follows. Define an extension of g , still called g , by

$$(2) \quad g(-p) = \left(\tan^2 \frac{\theta}{2} \cdot \overline{g(p)} \right)^{-1}, \quad -p \in -\Sigma.$$

Clearly g is holomorphic on $-\Sigma$ and continuous on $\tilde{\Sigma}$. Let $h: \mathbf{C} \rightarrow \mathbf{C}$ be a linear transformation which maps the circle $|w| = (\tan \frac{\theta}{2})^{-1}$ onto the imaginary axis of \mathbf{C} . Then the real part of $h \circ g$ is continuous on $\tilde{\Sigma}$ and harmonic on Σ and $-\Sigma$. Moreover we have

$$\begin{aligned} \operatorname{Re}[h \circ g(-p)] &= \operatorname{Re}[h \circ g(p)] = 0 \quad \text{for } p \in L, \\ \operatorname{Re}[h \circ g(-p)] &= -\operatorname{Re}[h \circ g(p)] \quad \text{for } -p \in -\Sigma. \end{aligned}$$

Hence by the reflection principle we conclude that $h \circ g$ is holomorphic on $\tilde{\Sigma}$, and so is g .

Using this extended map g , the extended 1-form dw , and the Weierstrass representation formula (1), we can obtain the extended minimal surface $\tilde{\Sigma}$. Here, for any $p \in \Sigma$, p^* is determined by integrating (1) over a contour on $\tilde{\Sigma}$ from a fixed point to $-p$. In case Σ is multiply connected it may happen that the reflection map $*$ maps $p \in \Sigma$ to infinitely many points $p^* \in \Sigma^*$. Also we should discuss the case where $g(p) = 0$ or ∞ . At such a point p , w cannot be a parameter of Σ . However dw and $\frac{1}{g} \pm g$ have a zero and a pole of the same order respectively at $-p$ as well as p . Consequently du and dv are holomorphic at $-p$ and thus Σ^* is well defined in a neighborhood of p^* . This proves conclusion (i).

Conclusion (ii) follows from the symmetry of $-\Sigma$ to Σ and the formula for z in (1).

(2) implies (iii).

Suppose p is a regular point. If the tangent plane to Σ at p is parallel to Π , then $dw = 0$ at p . For this reason, w is not a good conformal parameter near the point p . However, for any conformal parametrization in a neighborhood of p , the metric of the corresponding immersion is, by [BC],

$$ds^2 = \frac{1}{2}(1 + |g|^2)^2 |\omega|^2 = \frac{1}{2}(|g| + |g|^{-1})^2 |dw|^2.$$

Hence the ratio between the metrics at p and $-p$ is given by

$$\begin{aligned} \frac{ds^2(-p)}{ds^2(p)} &= \frac{\frac{1}{2}(\tan^{-2} \frac{\theta}{2} \cdot |g|^{-1} + \tan^2 \frac{\theta}{2} \cdot |g|)^2 |dw|^2}{\frac{1}{2}(|g| + |g|^{-1})^2 |dw|^2} \\ &= \left(\frac{\tan^2 \frac{\theta}{2} \cdot |g| + \tan^{-2} \frac{\theta}{2} \cdot |g|^{-1}}{|g| + |g|^{-1}} \right)^2. \end{aligned}$$

Note here that this ratio depends not on the parametrization of Σ but on the geometry of Σ . Furthermore one can easily show that

$$(3) \quad \begin{aligned} 0 &< \min \left(\tan^2 \frac{\theta}{2}, \tan^{-2} \frac{\theta}{2} \right) \\ &\leq \frac{ds(-p)}{ds(p)} \leq \max \left(\tan^2 \frac{\theta}{2}, \tan^{-2} \frac{\theta}{2} \right) < \infty. \end{aligned}$$

Therefore Σ^* is also regular at p^* . Since $\Sigma = (\Sigma^*)^*$ and $p = (p^*)^*$, we can obtain the converse similarly.

For (v), we note that in either case every contour in $\tilde{\Sigma}$ is nullhomotopic or homotopic to a contour in Σ and that no forms in formula (1) have real periods on Σ . Hence $*$ is single-valued and so, by (3), an immersion.

To prove (vi), we use a formula for the Gauss curvature of Σ [BC]:

$$K = - \left[\frac{4|g'|}{|f|(1 + |g|^2)^2} \right]^2.$$

The curvature ratio between p and $-p$ is given by

$$\frac{K(-p)}{K(p)} = \frac{\left[\frac{4|g'|}{\tan^6 \frac{\theta}{2} \cdot |g|^3 (1 + \tan^{-4} \frac{\theta}{2} \cdot |g|^{-2})^2} \right]^2}{\left[\frac{4|g'|}{|g|^{-1} (1 + |g|^2)^2} \right]^2} = \frac{\tan^4 \frac{\theta}{2} \cdot (1 + |g|^2)^4}{(1 + \tan^4 \frac{\theta}{2} \cdot |g|^2)^4}.$$

Therefore

$$\begin{aligned} 0 &< \min \left(\tan^{12} \frac{\theta}{2}, \tan^{-4} \frac{\theta}{2} \right) \\ &\leq \frac{K(-p)}{K(p)} \leq \max \left(\tan^{12} \frac{\theta}{2}, \tan^{-4} \frac{\theta}{2} \right) < \infty, \end{aligned}$$

and the conclusion follows.

Finally it is not difficult to see that (vii) can be derived from (3). Thus the proof of the theorem is now complete.

COROLLARY. *Let Σ be a complete minimal surface of finite total curvature in \mathbf{R}^3 . If an end E of Σ meets a plane along ∂E at a constant angle, then Σ is the catenoid.*

Proof. From Theorem 1 it follows that $\bar{E} = E \cup E^*$ is a complete minimal surface of finite total curvature with two ends. \bar{E} must then be the catenoid [L]. Obviously, by the unique continuation property of a minimal surface, we have $\bar{E} = \Sigma$.

Let Σ be a minimal surface in \mathbf{R}^3 with Gauss map g . For any real number $0 < r < \infty$, let us denote by Σ_r the minimal immersion of Σ into \mathbf{R}^3 defined by the formula

$$\begin{aligned} x &= \operatorname{Re} \int^w \frac{1}{2} \left(-rg + \frac{1}{rg} \right) dw, \\ y &= \operatorname{Re} \int^w \frac{i}{2} \left(rg + \frac{1}{rg} \right) dw, \\ z &= \operatorname{Re} \int^w dw. \end{aligned}$$

Then we see that every minimal surface can be deformed into a 1-parameter family of minimal surfaces and that this deformation preserves the z -coordinate and multiplies the Gauss map by r .

THEOREM 2. *Assume $\Sigma \subset \mathbf{R}^3$ is a minimal surface with nonempty boundary $\partial\Sigma$ which makes a constant angle θ with a plane Π along $\partial\Sigma \cap \Pi$.*

(i) *For any real number $0 < r < \infty$, the minimal surface Σ_r makes a constant angle $\phi = 2 \tan^{-1}(\frac{1}{r} \tan \frac{\theta}{2})$ with Π along $\partial\Sigma_r \cap \Pi$.*

(ii) *There exists a positive real number s such that the minimal surface Σ_s meets Π orthogonally along $\partial\Sigma_s \cap \Pi$, and the analytic extension $\bar{\Sigma}$ of Σ is the same as $(\Sigma_s \cup (\Sigma_s)^*)_{1/s}$, where $(\Sigma_s)^*$ is the usual reflection (mirror image) of Σ_s with respect to Π .*

Proof. (i) By hypothesis, $|g(p)| = (\tan \frac{\theta}{2})^{-1}$ for all $p \in \partial\Sigma \cap \Pi$. Then

$$|rg(p)| = r \left(\tan \frac{\theta}{2} \right)^{-1} = \left(\tan \frac{\phi}{2} \right)^{-1},$$

where $\phi = 2 \tan^{-1}(\frac{1}{r} \tan \frac{\theta}{2})$. Since the deformation of Σ into Σ_r

preserves the z -coordinate and multiplies the Gauss map by r , Σ_r meets Π along $\partial\Sigma_r \cap \Pi$ at the constant angle ϕ .

(ii) Let s be the positive real number satisfying

$$2 \tan^{-1} \left(\frac{1}{s} \tan \frac{\theta}{2} \right) = 90^\circ.$$

Then Σ_s meets Π orthogonally. Clearly we have

$$(\overline{\Sigma})_s = \overline{(\Sigma_s)}.$$

Since $\overline{(\Sigma_s)}$ is the union of Σ_s and its mirror image $(\Sigma_s)^*$ with respect to Π , we conclude that

$$\overline{\Sigma} = ((\overline{\Sigma})_s)_{1/s} = (\overline{(\Sigma_s)})_{1/s} = (\Sigma_s \cup (\Sigma_s)^*)_{1/s}.$$

REMARKS. 1. A nice example of the analytic reflection can be seen in the catenoid. Let Π_1, Π_2 , and Π_3 be the parallel planes with $\text{dist}(\Pi_1, \Pi_2) = \text{dist}(\Pi_2, \Pi_3)$. Let Σ be the catenoid whose ends are parallel to the Π_i . Then Σ intersects the Π_i along circles at constant angles α_i . Assume $\alpha_2 \neq 90^\circ$ and define D_1, D_3 to be the two bounded components of $\Sigma \sim (\Pi_1 \cup \Pi_2 \cup \Pi_3)$. Then D_3 is the analytic reflection of D_1 with respect to Π_2 and D_1 is that of D_3 . If we define D_+, D_- to be the components of $\Sigma \sim \Pi_2$, then $D_+ = (D_-)^*$ and $D_- = (D_+)^*$.

2. Embeddedness of Σ does not necessarily imply that of Σ^* .

3. If the tangent plane to Σ at p is parallel to Π , so is the tangent plane to Σ^* at p^* . This is clear in view of Theorem 1(iii).

4. Given an angle $0 < \theta < 90^\circ$, two points p_1, p_2 on Π , and a curve $\Gamma \subset \mathbf{R}^3$ from p_1 to p_2 , one can construct an area minimizing surface Σ with the fixed boundary Γ and a free boundary $L \subset \Pi$ along which Σ meets Π at the angle θ as follows. Let Γ_1 be the line segment on Π from p_2 to p_1 . We regard Γ, Γ_1 as 1-dimensional sets with orientation, i.e., 1-currents. Let S be a surface with $\partial S = \Gamma \cup \Gamma_S, \Gamma_S \subset \Pi$. Give S and Γ_S orientations, S is then called a 2-current, in such a way that $\partial S = \Gamma - \Gamma_S$. As sets, Γ_1 and Γ_S bound a planar domain $D \subset \Pi$ with $\partial D = \Gamma_1 \cup \Gamma_S$. Giving suitable orientations to each component of D , we can make D into a 2-current such that $\partial D = \Gamma_1 + \Gamma_S$. Let us fix an orientation of the plane Π . Then D , as a set, is divided into two disjoint domains D_1, D_2 such that D_1 and D_2 with the orientation inherited from Π can be thought of as 2-currents, and

$$D = D_1 - D_2.$$

Now we define $\tilde{A}(S)$, the *modified area* of S , by

$$\tilde{A}(S) = \text{Area}(S) + \cos \theta [\text{Area}(D_1) - \text{Area}(D_2)].$$

Let \mathcal{F} be the family of all 2-currents S such that $\partial S - \Gamma$ is a 1-current on Π . Then it is not difficult to see that $-\infty < \inf\{\tilde{A}(S) : S \in \mathcal{F}\}$ and therefore we can find a modified area minimizing current Σ . Σ , as a set, is a desired minimal surface, and by [T] it is Hölder continuously differentiable up to its free boundary. Thus we can analytically extend Σ across its free boundary $\partial\Sigma \sim \Gamma$ to obtain the θ -reflection Σ^* of Σ with respect to Π .

Open problems. 1. Is it possible to extend Theorem 1 to the case of a constant mean curvature surface in \mathbf{R}^3 or a minimal hypersurface in \mathbf{R}^n ? It is well known that the answer is yes if a constant mean curvature surface (a minimal hypersurface respectively) meets a plane (a hyperplane respectively) orthogonally.

2. As a generalization of Corollary, is it true that if a complete constant mean curvature surface Σ of finite topological type intersects a plane at a constant angle $\neq 90^\circ$, then Σ is a Delaunay's surface?

3. Given a compact convex body U in \mathbf{R}^3 , one can construct a minimal disk D in U which makes a constant contact angle θ with the convex boundary ∂U ? Grüter and Jost [GJ] solved the problem affirmatively when $\theta = 90^\circ$.

4. Most complete minimal surfaces are known to have at least one plane of symmetry. However, some complete immersed minimal surfaces of genus zero constructed by H. Karcher do not have a plane of symmetry. Nevertheless, given a complete minimal surface in \mathbf{R}^3 , can one find a plane which intersects the minimal surface at a constant angle?

Acknowledgment. This paper was written while I was visiting Bonn University through SFB 256 in the Summer 1989. I wish to express my gratitude to M. Grüter, S. Hildebrandt, and H. Karcher for their hospitality.
