DILATION OF MARKOVIAN COCYCLES ON A VON NEUMANN ALGEBRA

Debashish Goswami, J. Martin Lindsay, Kalyan B. Sinha,
and Stephen J. Wills

We consider normal Markovian cocycles on a von Neumann algebra which are adapted to a Fock filtration. Every such cocycle k which is Markov-regular and consists of completely positive contractions is realised as a conditioned *-homomorphic cocycle. This amounts to a stochastic generalisation of a recent dilation result for norm-continuous normal completely positive contraction semigroups. To achieve this stochastic dilation we use the fact that k is governed by a quantum stochastic differential equation whose coefficient matrix has a specific structure, and extend a technique for obtaining stochastic flow generators from Markov semigroup generators, to the context of cocycles. Number/exchange-free dilatability is seen to be related to locality in the case where the cocycle is a Markovian semigroup. In the same spirit unitary dilations of Markov-regular contraction cocycles on a Hilbert space are also described. The paper ends with a discussion of connections with measure-valued diffusion.

0. Introduction.

Let $(\mathcal{P}_t)_{t \geq 0}$ be an ultraweakly continuous completely positive contraction semigroup on a von Neumann algebra $\mathcal{M}$. A natural problem is to seek a *dilation* of $\mathcal{P}$. This has various interpretations (see e.g., [**EvL**], [**Vin**], [**Küm**], [**Sa1**], [**Bha**]); the following is a minimum: A family $(j_t)_{t \geq 0}$ of normal *-homomorphisms of $\mathcal{M}$ into a larger algebra $\mathcal{N}$, equipped with a conditional expectation $\mathbb{E} : \mathcal{N} \to \mathcal{M}$, such that $\mathbb{E} \circ j_t = \mathcal{P}_t$. One usually further requires j to satisfy a semigroup law. From a physical point of view it is in many situations appropriate to choose the algebra $\mathcal{N}$, to be of the form $\mathcal{M} \otimes \mathcal{B}_{\mathsf{k}}$ where $\mathcal{B}_{\mathsf{k}} = \mathcal{B}(\Gamma_{\mathsf{k}})$ and Γ_{k} is the symmetric Fock space over $L^2(\mathbb{R}_+; \mathsf{k})$ for some Hilbert space k (see e.g., [**AAFL**]). In this case the dilation is of *Evans-Hudson type* ([**EH1**]) if $\mathbb{E}$ is chosen to be the vacuum expectation and if j satisfies a quantum stochastic (QS) differential equation of the form

$$(0.1) \qquad dj_t = j_t \circ \phi^{\alpha}_{\beta} \, d\Lambda^{\beta}_{\alpha}(t), \quad j_0(a) = a \otimes 1,$$

in which Λ denotes the matrix of fundamental QS integrators ([**HuP**], [**Par**], [**Mey**]) and ϕ is the coefficient matrix of a bounded sesquilinear map $\widehat{\mathsf{k}} \times \widehat{\mathsf{k}} \to \mathcal{B}(\mathcal{A})$, both defined with respect to some basis of the *noise dimension space* k. This kind of stochastic dilation satisfies a cocycle relation (with respect to the shift of the quantum noise) rather than a semigroup law, however combining j with the shift does result in a semigroup on $\mathcal{M} \otimes \mathcal{B}_{\mathsf{k}}$. In the recent paper [**GS**] it is shown that an E-H dilation exists when the semigroup $\mathcal{P}$ has bounded generator. A coordinate-free formulation of QS calculus is given in [**GS**], using Hilbert W^*-modules, and this copes well with the fact that the noise dimension space k required for the dilation may in general be nonseparable.

This dilation picture has the following natural generalisation: Let $\mathcal{B}_J^0 = \mathcal{B}(\Gamma_{J,\mathsf{k}_0})$ where Γ_{J,k_0} is the symmetric Fock space over $L^2(J; \mathsf{k}_0)$ for a subinterval J of $\mathbb{R}_+$ and a Hilbert space k_0, writing simply $\mathcal{B}^0$ when $J = \mathbb{R}_+$. Then $\mathcal{B}^0$ carries the filtration of subalgebras $(\mathcal{B}_{[0,t[}^0)_{t \geq 0}$ and the semigroup of shifts $\sigma = (\sigma_t : \mathcal{B}^0 \to \mathcal{B}_{[t,\infty[}^0 \subset \mathcal{B}^0)_{t \geq 0}$. Suppose that $k = (k_t : \mathcal{M} \to \mathcal{M} \otimes \mathcal{B}^0)_{t \geq 0}$ is an ultraweakly continuous family of completely positive (CP) normal contractions which is *adapted* to the filtration and is a *cocycle* with respect to the semigroup of shifts:

$$k_{s+t} = \widehat{k}_s \circ \sigma_s \circ k_t, \quad k_0(a) = a \otimes 1,$$

where $\widehat{k}_s$ is the normal extension of k_s to a map $\mathcal{M} \otimes \mathcal{B}_{[s,\infty[}^0 \to \mathcal{M} \otimes \mathcal{B}^0$ ([**LW2**]). Is there a Hilbert space $\mathsf{k} \supset \mathsf{k}_0$ and a *-homomorphic cocycle $j = (j_t : \mathcal{M} \to \mathcal{M} \otimes \mathcal{B}_{\mathsf{k}})_{t \geq 0}$ satisfying a QS differential equation of the form (0.1), such that $\mathbb{E}_0 \circ j_t = k_t$ where $\mathbb{E}_0$ is now the conditional expectation which averages out the quantum noise provided by the supplementary Hilbert space $\mathsf{k} \ominus \mathsf{k}_0$? In other words, subject to regularity, can every CP contraction cocycle be realised as a conditioned *-homomorphic cocycle? Note that averaging out *all* of the noise from such a Markovian cocycle yields an ultraweakly continuous CP contraction semigroup $(\mathcal{P}_t = \mathbb{E} \circ k_t)_{t \geq 0}$, called the *Markov semigroup* of the cocycle.

The unity of these ideas is further brought out by the recent paper [**LW2**] where, following [**Bra**], every such cocycle k which is Markov-regular (that is, whose Markov semigroup $\mathcal{P}$ is norm-continuous) is seen to satisfy a QS differential equation of the form (0.1). In the deterministic case the cocycle reduces to a semigroup and the equation is $d\mathcal{P}_t = \mathcal{P}_t \circ \theta_0^0 \, dt$, simply expressing the fact that the semigroup has bounded generator θ_0^0. We are therefore addressing a *stochastic generalisation* of the dilation problem for CP contraction semigroups.

In the present paper we give an affirmative answer to the dilation problem for normal Markov-regular CP contraction cocycles on a von Neumann algebra which are adapted to the Fock filtration, thus extending the results

of [**GS**]. The construction is based on the infinitesimal structure of CP flows obtained in [**LiP**] and [**LW1**], combined with the techniques introduced in [**GS**] to obtain a stochastic flow generator from the generator of a CP contraction semigroup. We also consider the dilation problem for Markovian contraction cocycles on a Hilbert space. Again every such cocycle that is Markov-regular is governed by a QS differential equation, this time of the Hudson-Parthasarathy type:

$$(0.2) \qquad dX_t = X_t F^\alpha_\beta \, d\Lambda^\beta_\alpha(t), \quad X_0 = 1,$$

for a matrix F of bounded operators on the Hilbert space ([**LW2**], [**HuL**]); moreover the structure of the matrix is once again completely characterised ([**LW1**], [**Fag**], [**Mo2**]).

The plan of the paper is as follows: In Section 1 the basic terminology of quantum stochastic calculus, flows and cocycles is reviewed, and some key results are recalled. Section 2 reviews a characterisation of nonnegative (2×2) operator matrices that is used in the construction of the dilations, and in Section 3 the structure theorems for CP, and CP contraction, flow generators are refined to a form which facilitates stochastic dilation. The *-homomorphic dilations of CP contraction cocycles on a von Neumann algebra, and the unitary dilations of contraction cocycles on a Hilbert space, are constructed in Sections 4 and 6 respectively. In Section 5 CP contraction cocycles which have *-homomorphic stochastic dilations involving no number/exchange processes are characterised, and the connection with locality for quantum dynamical semigroups is discussed. The final section contains a discussion of how these ideas might be applied to the theory of measure-valued diffusions.

Dilation for CP flows in a rather different sense arise in the work of Belavkin ([**Be2**]). There the question raised is one of implementing a CP flow k by conjugation with a solution of a Hudson-Parthasarathy equation of the form (0.2): $k_t(a) = X_t(a \otimes 1)X_t^*$ — the flow being on the full algebra of operators on a Hilbert space. In this connection the implementation of CP flows on a von Neumann algebra, by inner perturbations of a *-homomorphic flow (in the spirit of [**EH2**]), is treated elsewhere ([**GLW**]).

1. Notation, terminology and background results.

The symmetric Fock space $\Gamma(\mathsf{H})$ over a Hilbert space H enjoys the exponential property $\Gamma(\mathsf{H}_1 \oplus \mathsf{H}_2) = \Gamma(\mathsf{H}_1) \otimes \Gamma(\mathsf{H}_2)$, where the natural isomorphism identifying the two spaces is most economically described in terms of exponential vectors: $\varepsilon(f_1, f_2) \longleftrightarrow \varepsilon(f_1) \otimes \varepsilon(f_2)$ ([**Par**]). For a Hilbert space k and subinterval J of $\mathbb{R}_+$ we denote $\Gamma(L^2(J; \mathsf{k}))$ by $\Gamma_{J,\mathsf{k}}$, the algebra of all bounded operators on $\Gamma_{J,\mathsf{k}}$ by $\mathcal{B}_{J,\mathsf{k}}$ and the vacuum vector $\varepsilon(0)$ in $\Gamma_{J,\mathsf{k}}$ by $\Omega_{J,\mathsf{k}}$, abbreviating these to $\Gamma_\mathsf{k}, \mathcal{B}_\mathsf{k}$ and Ω_k when $J = \mathbb{R}_+$. Two instances of the exponential property that will be important for us are when k is an orthogonal

sum of Hilbert spaces k_0 and k_1 and when $\mathbb{R}_+$ is a disjoint union of intervals J_1 and J_2. Thus $\Gamma_k = \Gamma_{k_0} \otimes \Gamma_{k_1}, \mathcal{B}_k = \mathcal{B}_{k_0} \otimes \mathcal{B}_{k_1}$ and $\mathcal{B}_{k_0} = \mathcal{B}_{k_0} \otimes 1 \subset \mathcal{B}_k$; $\Gamma_k = \Gamma_{J_1,k} \otimes \Gamma_{J_2,k}, \mathcal{B}_k = \mathcal{B}_{J_1,k} \otimes \mathcal{B}_{J_2,k}$ and $\mathcal{B}_{J_1,k} = \mathcal{B}_{J_1,k} \otimes 1 \subset \mathcal{B}_k$ (where 1 denotes the relevant identity operator) are all identifications that will be invoked without comment.

Let $\mathcal{A}$ be a unital C^*-algebra acting on an *initial Hilbert space* $\mathfrak{h}$. In [**LW1**] and [**LW2**] the *noise dimension space* k is assumed to be separable, the quantum stochastic calculus with infinite degrees of freedom developed there being that initiated by Mohari and Sinha ([**MoS**]). An orthonormal basis $(e_i)_{i \geq 1}$ of k is fixed, and the matrix of quantum stochastic integrators $[\Lambda^\alpha_\beta]_{\alpha,\beta \geq 0}$ is defined in terms of these vectors. They fall into four distinct classes: Λ^0_0 is the time component; $\Lambda^i_0 = A^i$, the ith annihilation component $(i \geq 1)$; $\Lambda^0_j = A^\dagger_j$, the jth creation component $(j \geq 1)$; and $\Lambda^i_j = N^i_j$, the (i,j)th number/exchange (also called gauge or preservation) component $(i,j \geq 1)$. The generator of a quantum stochastic flow is then a (possibly infinite) matrix $\theta = [\theta^\alpha_\beta]$ with entries in $\mathcal{B}(\mathcal{A})$. We write $\mathrm{M}_D(\mathcal{B}(\mathcal{A}))$, where $D = 1 + \dim k$, for the collection of these *mapping matrices*, and $\widehat{k}$ for the Hilbert space $\mathbb{C} \oplus k$. The Hilbert spaces $\mathfrak{h} \otimes \widehat{k}$ and $\oplus_{\gamma \geq 0} \mathfrak{h}$ may be identified by use of the fixed basis (adding $e_0 = 1 \in \mathbb{C}$ to give a basis of $\widehat{k}$). If θ is the stochastic generator of a CP contraction flow then the θ^α_β are components, with respect to this basis, of a *bounded* linear map, also denoted θ, from $\mathcal{A}$ into $\mathcal{A}'' \otimes \mathcal{B}(\widehat{k})$ ([**LW1**], Theorem 5.2). Whenever we use this identification and introduce components we shall use the Einstein summation convention and sum over repeated indices; greek indices running from 0, roman indices from 1.

This global boundedness property of CP contraction flow generators connects with the approach in [**GS**] where QS calculus is reformulated in a coordinate free manner using Hilbert W^*-modules. The modules encountered in [**GS**] are all of the form $\mathcal{M} \otimes \mathcal{B}(k_0; k_1)$, for Hilbert spaces k_0 and k_1, and von Neumann algebra $\mathcal{M}$. Such a module may be characterised as the set $\{T \in \mathcal{B}(\mathfrak{h} \otimes k_0; \mathfrak{h} \otimes k_1) : (a' \otimes 1_1)T = T(a' \otimes 1_0) \; \forall a' \in \mathcal{M}'\}$, and coincides with the closure of $\mathcal{M} \otimes_{\mathrm{alg.}} \mathcal{B}(k_0; k_1)$ in the weak, ultraweak, strong and ultrastrong topologies. We denote the topological dual of k by k^* and, since $\mathcal{B}(\mathbb{C}; k)$ is naturally identified with k, we write $\mathcal{M} \otimes k$ for $\mathcal{M} \otimes \mathcal{B}(\mathbb{C}; k)$.

Globally bounded mapping matrices on a C^*-algebra $\mathcal{A}$ will be written in block matrix form:

$$(1.1) \qquad \theta = \begin{bmatrix} \tau & \alpha \\ \chi & \nu - \iota \end{bmatrix}$$

where $\tau \in \mathcal{B}(\mathcal{A}), \alpha : \mathcal{A} \to \mathcal{A}'' \otimes k^*, \chi : \mathcal{A} \to \mathcal{A}'' \otimes k$ and $\nu, \iota : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}(k)$ are such that $\theta \in \mathrm{M}_D(\mathcal{B}(\mathcal{A}))$. Throughout the paper ι denotes the map $\iota(a) = a \otimes 1_k$ for the relevant k, and $\widehat{\theta}$ denotes the transformed mapping

matrix

$$(1.1)' \qquad \widehat{\theta} = \begin{bmatrix} \tau & \alpha \\ \chi & \nu \end{bmatrix}.$$

For a subspace k_0 of the noise dimension space k, the *vacuum conditional expectation* $\mathbb{E}_0 : \mathcal{A}'' \otimes \mathcal{B}_{\mathsf{k}} \to \mathcal{A}'' \otimes \mathcal{B}_{\mathsf{k}_0}$ is given by $\mathbb{E}_0[c] = E^* c E$ where E is the isometry $\mathfrak{h} \otimes \Gamma_{\mathsf{k}_0} \ni \xi \mapsto \xi \otimes \Omega_{\mathsf{k}_0^\perp} \in \mathfrak{h} \otimes \Gamma_{\mathsf{k}}$. When $\mathsf{k}_0 = \{0\}$ it is denoted simply by $\mathbb{E}$.

Processes on a C^*-algebra $\mathcal{A}$ with separable noise dimension space k are defined in generality in [**LW1**]. Here, apart from in Theorem 3.1, we are exclusively concerned with *contraction processes*, that is pointwise weakly measurable families of contractions $k = (k_t)_{t \geq 0}$ which are adapted to the Fock filtration: $k_t : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}_{[0,t[,\mathsf{k}} \otimes 1 \subset \mathcal{A}'' \otimes \mathcal{B}_{\mathsf{k}}$. When $\mathcal{A}$ is a von Neumann algebra, k is called *normal* if each map k_t is normal. Fock-adapted *Markovian cocycles* k on a C^*-algebra $\mathcal{A}$ are defined in [**LW2**], following Bradshaw who defined normal *-homomorphic cocycles on a von Neumann algebra by (1.2) below ([**Bra**]). They are required to satisfy a Feller property which includes invariance of the algebra under the maps $\mathcal{P}_t = \mathbb{E} \circ k_t$ ($t \geq 0$), which comprise the *Markov semigroup* of k. A Markovian CP contraction cocycle is called *Markov-regular* when its Markov semigroup is norm continuous. For normal CP contraction processes k on a von Neumann algebra $\mathcal{M}$, the cocycle condition reads

$$(1.2) \qquad k_{s+t} = \widehat{k}_s \circ \sigma_s \circ k_t \quad (s, t \geq 0),$$

where σ_s is the right shift $\mathcal{M} \otimes \mathcal{B}_{\mathsf{k}} \to \mathcal{M} \otimes \mathcal{B}_{[s,\infty[,\mathsf{k}} \subset \mathcal{M} \otimes \mathcal{B}_{\mathsf{k}}$, and $\widehat{k}_s$ is the normal extension of the map $\mathcal{M} \otimes_{\mathrm{alg.}} \mathcal{B}_{[s,\infty[,\mathsf{k}} \to \mathcal{M} \otimes \mathcal{B}_{\mathsf{k}}$ given by $a \otimes b \mapsto k_s(a)(1 \otimes b)$. In the case where $\mathcal{A}$ is a von Neumann algebra, k is one-dimensional and k is normal, unital and *-homomorphic, the following result was established by Bradshaw ([**Bra**]). It has been extended to a class of such cocycles whose Markov semigroup is only assumed to be ultraweakly continuous in [**AcM**].

Theorem 1.1 ([**LW2**])**.** *Let k be a CP contraction process on a unital C^*-algebra $\mathcal{A}$, with separable noise dimension space k. Then the following are equivalent*:

   (i) *k is a Markov-regular cocycle.*
   (ii) *k weakly satisfies a QS differential equation of the form*

$$(1.3) \qquad dk_t = k_t \circ \theta^\alpha_\beta \, d\Lambda^\beta_\alpha(t), \quad k_0(a) = a \otimes 1$$

     for a mapping matrix $\theta \in \mathrm{M}_D(\mathcal{B}(\mathcal{A}))$.

In this case k satisfies the equation strongly and θ defines a (completely) bounded operator $\mathcal{A} \to \mathcal{B}(\mathfrak{h} \otimes \widehat{\mathsf{k}})$. Moreover, if $\mathcal{A}$ is a von Neumann algebra then k is normal if and only if θ is.

In view of this result we use the terminology Markovian cocycle and stochastic flow interchangeably. Let k and j be a pair of contraction processes on $\mathcal{A}$ with noise dimension spaces k_0 and k respectively, where k_0 is a subspace of k. We shall call j a *stochastic dilation* of k if

$$k_t = \mathbb{E}_0 \circ j_t \quad (t \geq 0).$$

Thus, in this terminology, if k is a Markovian cocycle with associated Markov semigroup $\mathcal{P}$ then k is a stochastic dilation of $\mathcal{P}$. When j and k are processes that satisfy QS differential equations of the form (1.3) with noise dimension spaces k and $\mathsf{k}_0 \subset \mathsf{k}$ respectively, it is easy to determine when j is a stochastic dilation of k by inspecting their generators.

Lemma 1.2. *Let* $\theta : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}(\widehat{\mathsf{k}_0})$ *and* $\phi : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}(\widehat{\mathsf{k}})$ *be bounded mapping matrices that weakly generate contraction flows* k *and* j, *with noise dimension spaces* k_0 *and* $\mathsf{k} = \mathsf{k}_0 \oplus \mathsf{k}_1$ *respectively. Then* j *is a stochastic dilation of* k *if and only if* ϕ *has block matrix form*

$$(1.4) \qquad\qquad \phi = \begin{bmatrix} \theta & * \\ * & * \end{bmatrix}.$$

Proof. If j is a stochastic dilation of k then, for all $u, v \in \mathfrak{h}$ and $f^0, g^0 \in L^2(\mathbb{R}_+; \mathsf{k}_0)$,

$$\langle u\varepsilon(f^0), k_t(a)v\varepsilon(g^0)\rangle = \langle u\varepsilon(f^0, 0), j_t(a)v\varepsilon(g^0, 0)\rangle.$$

Applying the first fundamental formula of quantum stochastic calculus to each side, differentiating the resulting expressions at $t = 0$, and varying the test functions f^0 and g^0 reveals that ϕ has the form (1.4). Conversely, if ϕ has the form (1.4) then the process $\mathbb{E}_0 \circ j$ is also a weak solution of the QS differential equation satisfied by k. Thus by uniqueness of solutions ([**LW1**], Theorem 3.1) $k = \mathbb{E}_0 \circ j$. $\qquad\square$

For a unital C^*-algebra $\mathcal{A}$ acting on the Hilbert space $\mathfrak{h}$, a representation (π, H) of $\mathcal{A}$, and operators $R \in \mathcal{B}(\mathfrak{h}; \mathsf{H})$ and $H \in \mathcal{B}(\mathfrak{h})$ we write $\delta_{R,\pi}$ and $\mathcal{L}_{R,\pi,H}$ for the operators given by

$$\delta_{R,\pi}(a) = Ra - \pi(a)R,$$

$$\mathcal{L}_{R,\pi,H}(a) = R^*\pi(a)R - \tfrac{1}{2}\{R^*R, a\} + i[H, a].$$

Thus $\delta_{R,\pi} : \mathcal{A} \to \mathcal{B}(\mathfrak{h}; \mathsf{H})$ is a π-derivation, and $\mathcal{L}_{R,\pi,H} : \mathcal{A} \to \mathcal{B}(\mathfrak{h})$ satisfies

$$(1.5) \qquad \partial\mathcal{L}_{R,\pi,H}(a, b) = \delta_{R,\pi}(a)^*\delta_{R,\pi}(b) + a^*R^*\pi(1)^\perp Rb$$

where, for a linear map $\tau : \mathcal{A} \to \mathcal{B}(\mathfrak{h})$, $\partial\tau : \mathcal{A} \times \mathcal{A} \to \mathcal{B}(\mathfrak{h})$ is the sesquilinear map defined by

$$\partial\tau(a, b) = \tau(a^*b) - a^*\tau(b) - \tau(a^*)b + a^*\tau(1)b.$$

The map τ is called *real* if it satisfies $\tau^\dagger = \tau$, where $\tau^\dagger$ is defined by $\tau^\dagger(a) = \tau(a^*)^*$. The following result in contained in [**ChE**]:

Theorem 1.3. *Let* $(\tau, \rho, \mathsf{H}, \delta)$ *consist of a map* $\tau \in \mathcal{B}(\mathcal{A})$, *a representation* (ρ, H) *of* $\mathcal{A}$, *and a* ρ-*derivation* $\delta : \mathcal{A} \to \mathcal{B}(\mathfrak{h}; \mathsf{H})$ *satisfying* $\partial \tau(a, b) = \delta(a)^* \delta(b)$ *and* $\delta(1) = 0$. *Then there is an operator* $R \in \mathcal{B}(\mathfrak{h}; \mathsf{H})$ *which lies in the ultraweak closure of* $\operatorname{Lin}\{\delta(a)b : a, b \in \mathcal{A}\}$ *and an element* $h \in \mathcal{A}''$ *such that*

$$\delta(\cdot) = \delta_{R,\rho}(\cdot) \text{ and } \tau(\cdot) = \mathcal{L}_{R,\rho,h}(\cdot) + \tfrac{1}{2}\{\tau(1), \cdot\}.$$

If τ *is real then* h *may be chosen so that* $h = h^*$.

2. Nonnegative operator matrices.

In this section we recall a characterisation of nonnegative operator block matrices that will be exploited in the construction of dilations. Parts (a) and (b) of the lemma below are classical and can be traced back as far as Schur — see [**FoF**], p. 547 for historical comments. We include a proof for the convenience of the reader. Part (c) is the special case required for the following section.

Lemma 2.1. *Let* $T \in \mathcal{B}(\mathsf{H}_1 \oplus \mathsf{H}_2)$ *for Hilbert spaces* H_1 *and* H_2.

(a) *The following are equivalent*:
  (i) $T \geq 0$.
  (ii) *In block matrix form*

$$(2.1) \qquad T = \begin{bmatrix} A & A^{1/2}VD^{1/2} \\ D^{1/2}V^*A^{1/2} & D \end{bmatrix}$$

  where $A, D \geq 0$ *and* $V \in \mathcal{B}(\mathsf{H}_2; \mathsf{H}_1)$ *is a contraction.*
(b) *There is a representation* (2.1) *in which*

$$(2.2) \qquad \operatorname{Ker} V \supset \operatorname{Ker} D \text{ and } \operatorname{Ran} V \subset \overline{\operatorname{Ran} A};$$

  this V *is unique.*
(c) *If the Hilbert spaces are of the form* $\mathsf{H} \otimes \mathfrak{h}_1$ *and* $\mathsf{H} \otimes \mathfrak{h}_2$ *respectively, and* T *belongs to* $\mathcal{C} \otimes \mathcal{B}(\mathfrak{h}_1 \oplus \mathfrak{h}_2)$ *for a von Neumann algebra* $\mathcal{C}$ *acting on* H, *then the unique contraction* V *satisfying* (2.1) *and* (2.2) *belongs to the* W^*-*module* $\mathcal{C} \otimes \mathcal{B}(\mathfrak{h}_2; \mathfrak{h}_1)$.

Proof. If (a)(ii) holds then T may be written

$$\begin{bmatrix} A^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} \left\{ \begin{bmatrix} V \\ 1 \end{bmatrix} \begin{bmatrix} V^* & 1 \end{bmatrix} + \begin{bmatrix} 1 - VV^* & 0 \\ 0 & 0 \end{bmatrix} \right\} \begin{bmatrix} A^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}$$

which is manifestly nonnegative.

Conversely, if T is nonnegative with block matrix form $\begin{bmatrix} A & B \\ C & D \end{bmatrix}$ then obviously $A, D \geq 0$ and $C = B^*$. By the Cauchy-Schwarz inequality,

$$\begin{aligned}
|\langle \xi, B\eta \rangle|^2 &= \left| \left\langle \begin{pmatrix} \xi \\ 0 \end{pmatrix}, T \begin{pmatrix} 0 \\ \eta \end{pmatrix} \right\rangle \right|^2 \\
&\leq \left\langle \begin{pmatrix} \xi \\ 0 \end{pmatrix}, T \begin{pmatrix} \xi \\ 0 \end{pmatrix} \right\rangle \left\langle \begin{pmatrix} 0 \\ \eta \end{pmatrix}, T \begin{pmatrix} 0 \\ \eta \end{pmatrix} \right\rangle = \|A^{1/2}\xi\|^2 \, \|D^{1/2}\eta\|^2.
\end{aligned}$$

First note that this implies that

$$\|B\eta\| \leq \|A^{1/2}\| \, \|D^{1/2}\eta\| \quad \forall \eta \in \mathsf{H}_2,$$

from which it follows that there is a (unique) operator $J \in \mathcal{B}(\mathsf{H}_2; \mathsf{H}_1)$ satisfying

$$B = JD^{1/2} \text{ and } \operatorname{Ker} J \supset \operatorname{Ker} D^{1/2}.$$

Now substitute this back into the Cauchy-Schwarz estimate:

$$|\langle J^*\xi, D^{1/2}\eta \rangle| \leq \|A^{1/2}\xi\| \, \|D^{1/2}\eta\|.$$

Since $\overline{\operatorname{Ran}} J^* = (\operatorname{Ker} J)^\perp \subset (\operatorname{Ker} D^{1/2})^\perp = \overline{\operatorname{Ran}} D^{1/2}$, this implies that

$$\|J^*\xi\| \leq \|A^{1/2}\xi\| \quad \forall \xi \in \mathsf{H}_1,$$

from which it follows that there is a (unique) contraction $W \in \mathcal{B}(\mathsf{H}_1; \mathsf{H}_2)$ satisfying

$$J^* = WA^{1/2} \text{ and } \operatorname{Ker} W \supset \operatorname{Ker} A^{1/2}.$$

Since W also satisfies $\overline{\operatorname{Ran}} W = \overline{\operatorname{Ran}} J^*$, if we put $V = W^*$ then we have $B = JD^{1/2} = A^{1/2}VD^{1/2}$ and $\operatorname{Ker} V = (\operatorname{Ran} W)^\perp = \operatorname{Ker} J \supset \operatorname{Ker} D^{1/2} = \operatorname{Ker} D$. Also $\operatorname{Ran} V \subset (\operatorname{Ker} W)^\perp \subset (\operatorname{Ker} A^{1/2})^\perp = \overline{\operatorname{Ran}} A^{1/2} = \overline{\operatorname{Ran}} A$, so (a)(ii) follows along with the first part of (b).

The uniqueness of V subject to (2.2) follows from the identity

$$\langle A^{1/2}\xi, VD^{1/2}\eta \rangle = \left\langle \begin{pmatrix} \xi \\ 0 \end{pmatrix}, T \begin{pmatrix} 0 \\ \eta \end{pmatrix} \right\rangle.$$

Under the conditions of (c) obviously $A \in \mathcal{C} \otimes \mathcal{B}(\mathsf{h}_1)$ and $D \in \mathcal{C} \otimes \mathcal{B}(\mathsf{h}_2)$. Moreover

$$\langle (c' \otimes 1_1)A^{1/2}\xi, V(d' \otimes 1_2)D^{1/2}\eta \rangle = \left\langle (c' \otimes 1) \begin{pmatrix} \xi \\ 0 \end{pmatrix}, T(d' \otimes 1) \begin{pmatrix} 0 \\ \eta \end{pmatrix} \right\rangle$$

for $c', d' \in \mathcal{C}'$, where $1_1, 1_2$ and 1 are the identities on $\mathsf{h}_1, \mathsf{h}_2$ and $\mathsf{h}_1 \oplus \mathsf{h}_2$ respectively; it follows that $V \in \mathcal{C} \otimes \mathcal{B}(\mathsf{h}_2; \mathsf{h}_1)$. $\qquad\square$

3. Structural form for a flow generator.

In this section we refine the characterisation of CP flow generators on a unital C^*-algebra $\mathcal{A}$ found in [**LiP**] and [**LW1**] in such a way that, when $\mathcal{A}$ is a von Neumann algebra and the flow is a normal contraction flow, the constituents of the generator may be used to determine a *-homomorphic stochastic dilation. The refinement uses the technique introduced in [**GS**] for dilating CP contraction semigroups.

Fix a separable noise dimension space k_0, with basis $(e_i)_{i \geq 1}$. To begin with we do not assume that k is a contraction flow. Therefore (when k_0 is infinite dimensional), its generator θ need not be bounded, and we must work with its components θ_β^α. Following $(1.1)'$ write $\begin{bmatrix} \tau & \chi_j^\dagger \\ \chi^i & \nu_j^i \end{bmatrix}$ for the (2×2) matrix of maps $\begin{bmatrix} \theta_0^0 & \theta_j^0 \\ \theta_0^i & \theta_j^i \end{bmatrix}, i, j \geq 1$ when θ is real. Let $\mathfrak{h}_{00}$ be the subspace of $\oplus_{\gamma \geq 0} \mathfrak{h} = \mathfrak{h} \otimes \widehat{\mathsf{k}_0}$ consisting of vectors with only finitely many nonzero components with respect to the chosen basis.

Theorem 3.1. *Let θ be a mapping matrix on the unital C^*- algebra $\mathcal{A}$ that weakly generates a stochastic flow k.*

(a) *The following are equivalent*:
   (i) *k is completely positive.*
   (ii) *θ is real and there is a quintuple $\mathcal{R} = (\mathsf{h}, \pi, h, d, \{w_j\})$ consisting of a Hilbert space h, a *-homomorphism $\pi : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h})$ and operators $h = h^* \in \mathcal{A}'', d \in \mathcal{A}'' \otimes \mathsf{h}$ and $w_j \in \mathcal{A}'' \otimes \mathsf{h}, j \geq 1$, such that*

(3.1i)
$$\begin{bmatrix} \tau(a) & \chi_j^\dagger(a) \\ \chi^i(a) & \nu_j^i(a) \end{bmatrix} = \begin{bmatrix} \mathcal{L}(a) + \frac{1}{2}\{t, a\} & \delta^\dagger(a)w_j + a(c^j)^* \\ w_i^*\delta(a) + c^i a & w_i^*\pi(a)w_j \end{bmatrix}$$

(3.1ii)
$$\pi(1)d = d \text{ and } \pi(1)w_j = w_j \quad \forall j$$

(3.1iii)
$$\operatorname{Ran} \pi(1) = \mathsf{H}$$

where $t = \tau(1), c^i = \chi^i(1), \delta = \delta_{d,\pi}, \mathcal{L} = \mathcal{L}_{d,\pi,h}$ and $\mathsf{H} = \overline{\mathsf{H}_0}$ with

$$\mathsf{H}_0 = \operatorname{Lin} \left\{ \delta(a)u^0 + \pi(a)w_j u^j : a \in \mathcal{A}, (u^\alpha) \in \mathfrak{h}_{00} \right\}.$$

(b) *If $\mathcal{R}_1$ and $\mathcal{R}_2$ are quintuples satisfying (3.1) then there is a unique partial isometry $V : \mathfrak{h} \otimes \mathsf{h}_1 \to \mathfrak{h} \otimes \mathsf{h}_2$ satisfying*

(3.2i)
$$V^*V = \pi_1(1); \quad VV^* = \pi_2(1)$$

(3.2ii)
$$\pi_2(a) = V\pi_1(a)V^*; \quad \delta_2 = V\delta_1; \quad w_j^2 = Vw_j^1.$$

Moreover $V \in \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h}_1; \mathsf{h}_2)$.

(c) *If $\mathcal{A}$ is a von Neumann algebra and $\mathcal{R}$ is a quintuple satisfying (3.1), then the representation $(\pi, \mathfrak{h} \otimes \mathsf{h})$ is normal if and only if each θ_β^α is.*

Proof. The implication (a)(ii) ⇒ (a)(i) is contained in [**LW1**], Theorem 4.1.

(a)(i) ⇒ (a)(ii): Suppose that k is completely positive. Then, by Theorem 4.1 of [**LW1**], θ is real and there is a quadruple $\mathcal{Q} = (\rho, \mathcal{H}, \gamma, \{W_i\})$ consisting of a representation $(\rho, \mathcal{H})$ of $\mathcal{A}$, a ρ-derivation $\gamma : \mathcal{A} \to \mathcal{B}(\mathfrak{h}; \mathcal{H})$ and a family of operators $\{W_i : i \geq 1\}$ in $\mathcal{B}(\mathfrak{h}; \mathcal{H})$ such that

(3.3i)
$$\begin{bmatrix} \partial\tau(a,b) & \chi_j^\dagger(a) \\ \chi^i(a) & \nu_j^i(a) \end{bmatrix} = \begin{bmatrix} \gamma(a)^*\gamma(b) & \gamma^\dagger(a)W_j + a\chi_j^\dagger(1) \\ W_i^*\gamma(a) + \chi^i(1)a & W_i^*\rho(a)W_j \end{bmatrix}$$

(3.3ii)
$$\rho \text{ is unital}$$

(3.3iii)
$$\mathcal{H} = \overline{\mathcal{H}_0}$$

where $\mathcal{H}_0 = \mathrm{Lin}\{\gamma(a)u^0 + \rho(a)W_i u^i : a \in \mathcal{A}, (u^\alpha) \in \mathfrak{h}_{00}\}$. For each unitary $u' \in \mathcal{A}'$ define bounded linear operators $\gamma^{u'} : \mathcal{A} \to \mathcal{B}(\mathfrak{h}; \mathcal{H})$ and $W_j^{u'} \in \mathcal{B}(\mathfrak{h}; \mathcal{H})$ by $\gamma^{u'}(a) = \gamma(a)u'$ and $W_j^{u'} = W_j u'$, and note the following relations:

$$\gamma^{u'}(a)^*\gamma^{u'}(b) = u'^*\partial\tau(a,b)u' = \partial\tau(a,b) = \gamma(a)^*\gamma(b);$$
$$(W_i^{u'})^*\gamma^{u'}(a) = u'^*W_i^*\gamma(a)u' = u'^*(\chi^i(a) - \chi^i(1)a)u' = W_i^*\gamma(a);$$
$$(W_i^{u'})^*\rho(a)W_j^{u'} = u'^*W_i^*\rho(a)W_j u' = u'^*\nu_j^i(a)u' = \nu_j^i(a);$$
$$\mathcal{H}_0^{u'} = \mathcal{H}_0.$$

In other words the quadruple $\mathcal{Q}^{u'} = (\rho, \mathcal{H}, \gamma^{u'}, \{W_i^{u'}\})$ also satisfies (3.3). Hence, by the uniqueness part of Theorem 4.1 in [**LW1**], there is a unique unitary operator $\rho'(u')$ on $\mathcal{H}$ such that

(3.4)
$$\rho'(u')W_i = W_i u'; \quad \rho'(u')\gamma(a) = \gamma(a)u';$$
$$\rho'(u')\rho(a) = \rho(a)\rho'(u').$$

The resulting map ρ' is easily seen to be a unitary representation of the group of unitaries in $\mathcal{A}'$ by checking matrix elements against vectors from the dense subspace $\mathcal{H}_0$. It follows that ρ' extends linearly to a normal, unital representation of $\mathcal{A}'$. Hence ([**Dix**], p. 61) there is a Hilbert space h and an isometry $V : \mathcal{H} \to \mathfrak{h} \otimes \mathsf{h}$ such that $\rho'(x') = V^*(x' \otimes 1)V$ and $p := VV^* \in \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h})$. Put $\mathsf{H} = V\mathcal{H}$ and define $\pi' : \mathcal{A}' \to \mathcal{B}(\mathfrak{h} \otimes \mathsf{h}), \pi : \mathcal{A} \to \mathcal{B}(\mathfrak{h} \otimes \mathsf{h}), \delta : \mathcal{A} \to \mathcal{B}(\mathfrak{h}; \mathfrak{h} \otimes \mathsf{h})$, and $w_j \in \mathcal{B}(\mathfrak{h}; \mathfrak{h} \otimes \mathsf{h})$ for $j \geq 1$, by

$$\pi'(x') = (x' \otimes 1)p, \ \pi(a) = V\rho(a)V^*, \ \delta(a) = V\gamma(a), \ w_j = VW_j.$$

Since $p \in \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h})$, algebraic manipulations applied to (3.4) reveal the following identities:

$$\pi(1) = p; \quad p\delta(a) = \delta(a); \quad pw_j = w_j,$$
$$\pi(a)(x' \otimes 1) = (x' \otimes 1)\pi(a) = \pi'(x')\pi(a),$$
$$\delta(a)x' = (x' \otimes 1)\delta(a),$$
$$w_j x' = (x' \otimes 1)w_j.$$

Thus $\pi(\mathcal{A}) \subset \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h}), \delta(\mathcal{A}) \subset \mathcal{A}'' \otimes \mathsf{h}$ and $w_j \in \mathcal{A}'' \otimes \mathsf{h}$. Moreover π is a representation, δ a π-derivation, and

$$\operatorname{Ran} \pi(1) = \operatorname{Ran} V = \overline{V(\mathcal{H}_0)} = \overline{\mathsf{H}_0} = \mathsf{H}.$$

Now $\delta(1) = 0$ and $\delta(a)^*\delta(b) = \partial\tau(a,b)$, from its definition. Thus by Theorem 1.3 there is some $d \in \overline{\operatorname{Lin}}^{\text{uw}}\{\delta(a)b : a,b\} \subset \mathcal{A}'' \otimes \mathsf{h}$ and $h = h^* \in \mathcal{A}''$ such that $\delta = \delta_{d,\pi}$ and $\tau(\cdot) = \mathcal{L}_{d,\pi,h}(\cdot) + \frac{1}{2}\{\tau(1),\cdot\}$. Note also that $\pi(1)d = d$ since $\delta(1) = 0$, which completes part (a).

(b) Writing H_i for $\operatorname{Ran} \pi_i(1) \subset \mathfrak{h} \otimes \mathsf{h}_i, i = 1,2$, Theorem 4.1 of [**LW1**] ensures the existence of a unique unitary operator $V_0 : \mathsf{H}_1 \to \mathsf{H}_2$ satisfying

$$V_0 w_j^1 = w_j^2; \quad V_0\delta_1 = \delta_2; \quad V_0\pi_1(a) = \pi_2(a)V_0.$$

Let V be the unique extension of V_0 to an operator $V : \mathfrak{h} \otimes \mathsf{h}_1 \to \mathfrak{h} \otimes \mathsf{h}_2$ that satisfies (3.2i). Then V satisfies (3.2ii), and is thus clearly the unique partial isometry satisfying (3.2). That V belongs to $\mathcal{A}'' \otimes \mathcal{B}(\mathsf{h}_1; \mathsf{h}_2)$ follows from the identity

$$(a' \otimes 1_i)(\delta_i(a)u^0 + \pi_i(a)w_j^i u^j) = \delta_i(a)a'u^0 + \pi_i(a)w_j^i a'u^j.$$

(c) In one direction this is trivial. To obtain normality of π from the normality of all of the θ_β^α it is enough to consider the restriction of π to $\pi(1)(\mathfrak{h} \otimes \mathsf{h})$ and apply [**LW1**], Theorem 4.1(d). □

Remark. If $\mathcal{A}$ is a von Neumann algebra, the initial space $\mathfrak{h}$ is separable, and each θ_β^α is ultraweakly continuous, then Proposition 4.2 of [**LW1**] implies that the representation space $\mathcal{H}$ in the quadruple $\mathcal{Q}$ is separable too, so that in particular the von Neumann algebra $\rho'(\mathcal{A}')'$ is σ-finite. In this case we may assume that the Hilbert space h in Theorem 3.1 is separable too (see [**Dix**], p. 62).

Theorem 3.2. *Let θ be a mapping matrix on the unital C^*-algebra $\mathcal{A}$ that weakly generates a stochastic flow k. The following are equivalent:*

(i) *k is a completely positive contraction cocycle.*

(ii) *θ is real and bounded, and there is a sextuple $\mathcal{S} = (\mathsf{h}, \pi, h, d, w, v)$ consisting of a Hilbert space h, a *-homomorphism $\pi : \mathcal{A} \to \mathcal{A}'' \otimes \mathcal{B}(\mathsf{h})$,*

*operators $h = h^* \in \mathcal{A}'', d \in \mathcal{A}'' \otimes \mathsf{h}$ and contractions $w \in \mathcal{A}'' \otimes \mathcal{B}(\mathsf{k}_0; \mathsf{h})$
and $v \in \mathcal{A}'' \otimes \mathsf{k}_0$ such that, in the notation of (1.1)$'$,*

$$(3.5\mathrm{i}) \qquad \widehat{\theta}(a) = \begin{bmatrix} \mathcal{L}(a) + \frac{1}{2}\{t, a\} & \delta^\dagger(a)w + ac^* \\ w^*\delta(a) + ca & w^*\pi(a)w \end{bmatrix}$$

$$(3.5\mathrm{ii}) \qquad \pi(1)d = d \ \textit{and} \ \pi(1)w = w$$

$$(3.5\mathrm{iii}) \qquad \operatorname{Ran}\pi(1) = \mathsf{H}$$

$$(3.5\mathrm{iv}) \qquad c = (1 - w^*w)^{1/2}v(-t)^{1/2}$$

$$(3.5\mathrm{v}) \qquad \operatorname{Ker} v \supset \operatorname{Ker} t \ \textit{and} \ \operatorname{Ran} v \subset \overline{\operatorname{Ran}}(1 - w^*w)$$

where $t = \tau(1) \leq 0, c = \chi(1), \delta = \delta_{d,\pi}, \mathcal{L} = \mathcal{L}_{d,\pi,h}$ and $\mathsf{H} = \overline{\mathsf{H}_0}$ with

$$\mathsf{H}_0 = \operatorname{Lin}\left\{\delta(a)u^0 + \pi(a)w(u^i) : a \in \mathcal{A}, (u^\gamma) \in \mathfrak{h}_{00}\right\}.$$

*Moreover, if $\mathcal{A}$ is a von Neumann algebra then the representation $(\pi, \mathfrak{h} \otimes \mathsf{h})$
of $\mathcal{A}$ appearing in $\mathcal{S}$ is normal if and only if the process k is normal.*

Proof. By Lemma 2.1 and [**LW1**], Proposition 5.1 and Theorem 5.2, (ii)
implies (i). Conversely if (i) holds then θ is bounded and satisfies $\theta(1) \leq 0$,
so that ν is a completely positive contraction. Letting $(\mathsf{h}, \pi, h, d, \{w_i\})$ be
the quintuple of Theorem 3.1, define an operator $w : \mathfrak{h} \otimes \mathsf{k}_0 \to \mathfrak{h} \otimes \mathsf{h}$ by
$w(v^i) = w_i v^i$, initially on vectors whose components are eventually zero.
Since $\pi(1)w_j = w_j$ for each j, and

$$\begin{aligned} \|w(v^i)\|^2 = \langle w_i v^i, w_j v^j \rangle &= \langle v^i, w_i^*\pi(1)w_j v^j \rangle \\ &= \langle v^i, \nu_j^i(1)v^j \rangle = \langle (v^i), \nu(1)(v^i) \rangle \leq \|(v^i)\|^2, \end{aligned}$$

it follows that w is a contraction. Since

$$(3.6) \qquad \begin{bmatrix} t & c^* \\ c & w^*w - 1 \end{bmatrix} \leq 0$$

the existence of $v \in \mathcal{A}'' \otimes \mathsf{k}_0$ satisfying (3.5iv) and (3.5v) follows from
Lemma 2.1. The remaining properties now follow easily from Theorem 3.1,
noting that when $\mathcal{A}$ is a von Neumann algebra, k is normal if and only if
each θ_β^α is normal by [**LW1**], Proposition 3.2. $\square$

Remarks. (i) The necessary conditions (3.5) for θ to weakly generate a CP
contraction cocycle k have been shown to be sufficient too ([**LW3**]), since
completely bounded mapping matrices are necessarily regular in the sense of
[**Mey**] and [**LW1**]. This also implies that θ strongly generates k. Uniqueness
of solutions ([**LW1**], Theorem 3.1) permits us to use the notation k^θ for the
cocycle generated by θ.

(ii) By [**LW1**] Proposition 5.1, k is unital if and only if c and t are both
zero and w is isometric; this implies that v is zero too.

Since we aim to dilate CP contraction cocycles to *-homomorphic cocy-cles, we need to be able to recognise from the generator when the flow is already *-homomorphic. This is addressed in the next result.

Proposition 3.3. *Let $\mathcal{M}$ be a von Neumann algebra acting on $\mathfrak{h}$, and let k be the flow generated by a (completely) bounded mapping matrix $\theta : \mathcal{M} \rightarrow \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}_0})$ which is expressible in the form* (3.5i) *for some normal represen-tation $(\pi, \mathfrak{h} \otimes \mathsf{h})$ of $\mathcal{M}$ and operators $c \in \mathcal{M} \otimes \mathsf{k}_0$, $h = h^* \in \mathcal{M}$, $d \in \mathcal{M} \otimes \mathsf{h}$ and $w \in \mathcal{M} \otimes \mathcal{B}(\mathsf{k}_0; \mathsf{h})$ satisfying* (3.5ii). *Then k is *-homomorphic if and only if:*

  (i) *w is a partial isometry,*
  (ii) *$wc = 0$,*
  (iii) *$c^*c = -t$,*
  (iv) *$ww^* \in \pi(\mathcal{M})'$, and*
  (v) *$ww^*\delta = \delta$.*

*In particular, if $ww^* = \pi(1)$ then k is *-homomorphic if and only if $wc = 0$ and $c^*c = -t$.*

Note. The hypotheses here imply complete positivity of k (by Theorem 3.1) but not contractivity. If however k is assumed to be contractive — equiva-lently $\theta(1) \leq 0$ — then there is an element v of $\mathcal{M} \otimes \mathsf{k}_0$ satisfying (3.5iv), and so (i) implies (ii).

Proof. The necessary and sufficient conditions for k to be *-homomorphic ([**LW1**], Theorem 6.5) may be written

$$(3.7) \qquad w^*\pi(a^*a)w = w^*\pi(a)^*ww^*\pi(a)w$$

$$(3.8) \qquad w^*\delta(a^*a) = w^*\delta(a^*)a + w^*\pi(a^*)w(w^*\delta(a) + ca)$$

$$(3.9) \qquad \begin{aligned}(w^*\delta(a) + ca)^*(w^*\delta(a) + ca) &= \partial\tau(a,a) - a^*ta \\ &= \delta(a)^*\delta(a) - a^*ta\end{aligned}$$

where (1.5) is used in the last line. Suppose (3.7)–(3.9) hold. Then, putting $a = 1$ and using the fact that $\pi(1)w = w$, reveals that $(w^*w)^2 = w^*w$, so that w is a partial isometry. Now $\delta(1) = 0$, so (3.8) and (3.9) with $a = 1$ give $wc = 0$ and $c^*c = -t$ respectively, which in turn implies that $\delta(a)^*(1 - ww^*)\delta(a) = 0$, and so $(1 - ww^*)\delta(a) = 0$. Also (3.7) implies that $w^*\pi(a)^*(1 - ww^*)\pi(a)w = 0$, so $(1 - ww^*)\pi(a)w = 0$, which implies that $\pi(a)ww^* = ww^*\pi(a)ww^*$, and taking adjoints shows that $ww^*\pi(a) = \pi(a)ww^*$. Thus (i)–(iv) hold.

Conversely if (i)–(iv) hold then (3.7)–(3.9) are easily verified. $\qquad\square$

Remark. Invoking [**GS**] Theorem 3.3.6, instead of [**LW1**] Theorem 6.5, the proposition remains true when the noise dimension space is no longer separable.

4. *-Homomorphic dilation.

In this section we give the main result of the paper, namely necessary and sufficient conditions for a Markovian cocycle to have a normal Markov-regular *-homomorphic dilation. We then consider various special cases.

Theorem 4.1. *Every normal Markov-regular completely positive contraction cocycle on a von Neumann algebra, with separable noise dimension space, admits a normal *-homomorphic stochastic dilation.*

Proof. Let k be a normal Markov-regular CP contraction cocycle on the von Neumann algebra $\mathcal{M}$ with separable noise dimension space k_0. By Theorem 3.2 its stochastic generator θ satisfies

$$\widehat{\theta}(a) = \begin{bmatrix} \tau(a) & \delta^\dagger(a)w + ac^* \\ w^*\delta(a) + ca & w^*\pi(a)w \end{bmatrix} = m\iota(a) + \iota(a)m^* + s^*\Psi(a)s$$

where

$$m = \begin{bmatrix} \frac{1}{2}t & 0 \\ c & 0 \end{bmatrix} \in \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}_0}), \quad s = \begin{bmatrix} 1 & 0 \\ 0 & w \end{bmatrix} \in \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}_0}; \widehat{\mathsf{h}}),$$

$\Psi : \mathcal{M} \to \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{h}})$ is the (transformed) mapping matrix

$$(4.1) \qquad\qquad\qquad \Psi = \begin{bmatrix} \mathcal{L} & \delta^\dagger \\ \delta & \pi \end{bmatrix},$$

and $(\mathsf{h}, \pi, h, d, w, v)$ is the sextuple $\mathcal{S}$ from the theorem satisfying (3.5). Set $\mathsf{k} = \mathsf{k}_0 \oplus \mathsf{k}_1 \oplus \mathsf{k}_2$ and let $\phi : \mathcal{M} \to \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}})$ be the mapping matrix defined by

$$\widehat{\phi}(a) = \begin{bmatrix} \tau(a) & \delta^\dagger(a)W + aC^* \\ W^*\delta(a) + Ca & W^*\pi(a)W \end{bmatrix} = M\iota(a) + \iota(a)M^* + S^*\Psi(a)S$$

where

$$M = \begin{bmatrix} \frac{1}{2}t & 0 \\ C & 0 \end{bmatrix} \in \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}}) \ \text{ and } \ S = \begin{bmatrix} 1 & 0 \\ 0 & W \end{bmatrix} \in \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}}; \widehat{\mathsf{h}}),$$

with $W = \begin{bmatrix} w & r & 0 \end{bmatrix}$ and $C = \begin{bmatrix} c & g & e \end{bmatrix}^\mathsf{T}$, and where the Hilbert spaces k_1 and k_2 and operators $r \in \mathcal{M} \otimes \mathcal{B}(\mathsf{k}_1; \mathsf{h}), g \in \mathcal{M} \otimes \mathsf{k}_1$ and $e \in \mathcal{M} \otimes \mathsf{k}_2$ are to be determined.

Since ϕ is unchanged if W is replaced by $\pi(1)W$, we may assume that $\pi(1)r = r$. By Lemma 1.2 k^ϕ is a stochastic dilation of k, and by Proposition 3.3 and the remarks following it, k^ϕ is *-homomorphic if and only if

$$(4.2) \quad q^2 = q \in \pi(\mathcal{M})', \ q\delta = \delta, \ wc + rg = 0 \ \text{ and } \ c^*c + g^*g + e^*e = -t,$$

where $q := ww^* + rr^*$. The choice $\mathsf{k}_1 = \mathsf{h}, \mathsf{k}_2 = \mathbb{C}$ and

$$r = (\pi(1) - ww^*)^{1/2}, \quad g = -wv(-t)^{1/2}, \quad e = (1 - v^*v)^{1/2}(-t)^{1/2},$$

satisfies these constraints since then $q = \pi(1)$, and by (3.5ii) and (3.5iv)

$$rg = -(\pi(1) - ww^*)^{1/2} wv(-t)^{1/2}$$
$$= -w(1 - w^*w)^{1/2} v(-t)^{1/2} = -wc,$$

and

$$t + g^*g + e^*e = (-t)^{1/2}[-1 + v^*w^*wv + (1 - v^*v)](-t)^{1/2}$$
$$= (-t)^{1/2}v^*(w^*w - 1)v(-t)^{1/2} = -c^*c.$$

$\square$

Remarks. The particular solution given above serves merely to establish the existence of stochastic dilations. More natural dilations arise in particular cases; moreover one may wish to preserve unitality under dilation. In the remarks below we simplify the constraints (4.2) by considering only dilations for which $q = \pi(1)$.

  (i) If $wc = 0$ then it is natural to choose $g = 0$, simplifying the constraints to a question of finding $r \in \mathcal{M} \otimes \mathcal{B}(\mathsf{k}_1; \mathsf{h})$ and $e \in \mathcal{M} \otimes \mathsf{k}_2$ satisfying

(4.2)′ $\qquad\qquad rr^* + ww^* = \pi(1) \quad \text{and} \quad c^*c + e^*e = -t.$

  (ii) If w is a partial isometry then r is necessarily a partial isometry and (using (3.5iv)) $wc = 0$ so (i) applies.

 (iii) If $ww^* = \pi(1)$ then (ii) applies, and since r is necessarily zero we may take $\mathsf{k}_1 = \{0\}$. Moreover, by Proposition 3.3, k is already *-homomorphic unless $c^*c \neq -t$, in which case we may take

$$\mathsf{k}_2 = \mathbb{C}, \quad C = \begin{bmatrix} c \\ (-t - c^*c)^{1/2} \end{bmatrix} \quad \text{and} \quad W = \begin{bmatrix} w & 0 \end{bmatrix}.$$

 (iv) If k has a conservative Markov semigroup then $t = 0$, and so v and c are zero. Also e and g are necessarily zero and we may take $\mathsf{k}_2 = \{0\}$. By (iii) k is already *-homomorphic unless $ww^* \neq \pi(1)$. In this case

$$\widehat{\phi}(a) = S^*\Psi(a)S \quad \text{for} \quad S = \begin{bmatrix} 1 & 0 & 0 \\ 0 & w & r \end{bmatrix},$$

with Ψ given by (4.1) and $r \neq 0$ satisfying (4.2)′.

  (v) If k is unital then $\theta(1) = 0$ (by [**LW1**], Proposition 5.1), (iv) applies and also w is necessarily isometric so (ii) applies too. Thus we are left with a choice of Hilbert space k_1 and partial isometry r in $\mathcal{M} \otimes \mathcal{B}(\mathsf{k}_1; \mathsf{h})$ whose final space is $\mathrm{Ran}(\pi(1) - ww^*)$. The resulting dilation will be unital if and only if r is isometric. In particular, the above scheme can yield a unital *-homomorphic dilation *with the choice* $\mathsf{k}_1 = \mathsf{h}$ if and only if the projection $(\pi(1) - ww^*)$ is Murray-von Neumann equivalent to the identity, relative to the von Neumann algebra $\mathcal{M} \otimes \mathcal{B}(\mathsf{h})$.

(vi) If $k_0 = \{0\}$ then there is no noise and so k is a semigroup, $\mathcal{P}$ say. Thus c, v and w are all zero, in particular (ii) applies. If $\mathcal{P}$ is unital then (iv) and (v) apply too, and in this case $S = \mathrm{diag}[1, r]$. The choice $k_1 = h$ and $r = \pi(1)$, so that $\widehat{\phi} = \Psi$, gives the dilation obtained in [**GS**]. If $\mathcal{P}$ is nonunital then, choosing $k_2 = \mathbb{C}$ and $k_1 = h$ yields the generator

$$(4.3) \qquad \phi = \begin{bmatrix} \tau & \delta^\dagger & \lambda^\dagger \\ \delta & \pi - \iota & 0 \\ \lambda & 0 & -\,\mathrm{id} \end{bmatrix},$$

in which λ denotes left multiplication by $e = (-t)^{1/2}$.

(vii) If $k_0 = \{0\}$ and $\mathcal{M} = \mathcal{B}(\mathfrak{h})$ where $\mathfrak{h}$ is infinite dimensional but separable, then (vi) applies and we may choose k_1 to be (at most) one dimensional. To see this let

$$\pi(a) = V^*(a \otimes 1_{h'})V \quad \text{with} \quad VV^* \in 1_\mathfrak{h} \otimes \mathcal{B}(h')$$

be the normal decomposition of the representation π. Then, since h' may be assumed to be separable, there is a partial isometry $U \in \mathcal{B}(\mathfrak{h}; \mathfrak{h} \otimes h')$ with final space $\mathrm{Ran}\, VV^*$. Putting $r = V^*U \in \mathcal{B}(\mathfrak{h}; \mathfrak{h} \otimes h)$ yields the transformed dilation generator

$$\widehat{\phi} = \begin{bmatrix} \tau & \gamma^\dagger & \lambda^\dagger \\ \gamma & \nu & 0 \\ \lambda & 0 & 0 \end{bmatrix},$$

where $\nu(a) = U^*(a \otimes 1_{h'})U$ and $\gamma = \delta_{D,\nu}$ for $D = U^*Vd$. If $\partial\tau = 0$ then $\delta = 0$ by (1.5), and it follows from Theorem 1.3 that we may take $k_1 = \{0\}$ in (4.3) which (unless $\mathcal{P}$ is already *-homomorphic) gives the generator

$$\phi = \begin{bmatrix} \tau & \lambda^\dagger \\ \lambda & -\,\mathrm{id} \end{bmatrix}.$$

If $\partial\tau \neq 0$ then it follows that π is nonzero and we may choose U to be isometric, making ν unital. When $\mathcal{P}$ is unital, so that k_2 may be chosen to be $\{0\}$, the resulting dilation is that obtained in [**HuS**].

Corollary 4.2 ([**GS**]). *Every norm-continuous normal completely positive contraction semigroup on a von Neumann algebra has an Evans-Hudson dilation.*

Corollary 4.3 ([**HuS**]). *Let $\mathfrak{h}$ be infinite dimensional and separable. Every norm-continuous normal completely positive unital semigroup on $\mathcal{B}(\mathfrak{h})$ has a unital Evans-Hudson dilation with one-dimensional quantum noise.*

5. Number/exchange-free dilation.

In this section we seek necessary and sufficient conditions for a CP contraction cocycle to have a Markov-regular *-homomorphic stochastic dilation involving no number/exchange processes. Creation/annihilation-free dilations are also considered. Some interesting connections with locality, for quantum dynamical semigroups, emerge.

Proposition 5.1. *Let k be a Markov-regular completely positive contraction cocycle on a von Neumann algebra $\mathcal{M}$, with separable noise dimension space k_0, and let $\theta = \begin{bmatrix} \tau & \chi^\dagger \\ \chi & \nu - \iota_0 \end{bmatrix}$ be its stochastic generator and $\mathcal{P}$ its Markov semigroup.*

(a) *Suppose that $\nu = \iota_0$. Then the following are equivalent*:
   (i) *k has a number/exchange-free *-homomorphic dilation.*
   (ii) *k is unital, χ is an ι_0-derivation and τ satisfies*

(5.1) $$\partial\tau(a,a) - \chi(a)^*\chi(a) = \gamma(a)^*\gamma(a)$$

   where $\gamma : \mathcal{M} \to \mathcal{M} \otimes k_1$ is an ι_1-derivation for some Hilbert space k_1.
(b) *Suppose that $\chi = 0$ and k is normal. Then the following are equivalent*:
   (i) *k has a creation/annihilation-free *-homomorphic dilation.*
   (ii) *$\mathcal{P}$ is *-homomorphic.*

Proof. (a) Suppose that k has a number/exchange-free *-homomorphic dilation. Then, by [**LW1**] Proposition 6.3 and Lemma 6.4, the generator of this dilation has the form

(5.2) $$a \mapsto \begin{bmatrix} l^*(a \otimes 1_k)l - \frac{1}{2}\{l^*l, a\} + i[h, a] & al^* - l^*(a \otimes 1_k) \\ la - (a \otimes 1_k)l & 0 \end{bmatrix}$$

where $l \in \mathcal{M} \otimes k$, $h = h^* \in \mathcal{M}$ and $k \supset k_0$. It follows that $\chi(a) = ma - (a \otimes 1_{k_0})m$, where $m = p_0 l \in \mathcal{M} \otimes k_0$, p_0 being the orthogonal projection $\mathfrak{h} \otimes k \to \mathfrak{h} \otimes k_0$, and so θ satisfies (ii).

Conversely, if θ has satisfies (ii) then by Theorem 1.3, $\chi(a) = ma - (a \otimes 1_{k_0})m$ and $\gamma(a) = na - (a \otimes 1_{k_1})n$ for some $m \in \mathcal{M} \otimes k_0$ and $n \in \mathcal{M} \otimes k_1$, and $\tau = \mathcal{L}_{l,\iota,h}$ where $\iota(a) = a \otimes 1_{k_0 \oplus k_1}$, $l = [m \ n]^\top$ and $h = h^* \in \mathcal{M}$, so that k has the number/exchange-free dilation with generator (5.2).

(b) First note that (ii) is equivalent to τ being a derivation. Since the creation component $\widetilde{\gamma}$ of a *-homomorphic dilation must satisfy $\tau(a^*a) - a^*\tau(a) - \tau(a)^*a = \widetilde{\gamma}(a)^*\widetilde{\gamma}(a)$ ([**LW1**], Section 6), (i) implies (ii).

Conversely, if (ii) holds then $\mathcal{P}$ is conservative and, since k is normal, Remark (iv) above applies, with $\delta = 0$, so k has a creation/annihilation-free *-homomorphic dilation. $\square$

Remark. From the structure of Markov-regular $*$-homomorphic generators without number/exchange coefficients (5.2) it is clear that on an abelian von Neumann algebra any nontrivial CP contraction cocycle requires number/exchange processes in its dilation. This is not so when the Markov semigroup is no longer assumed to be norm continuous ([**G**]).

Proposition 5.2. *Let k and θ be as in* Proposition 5.1, *and assume further that $\nu = \iota_0$ and χ is an ι_0-derivation. If k has a number/exchange-free $*$-homomorphic dilation then k is unital and τ satisfies*

$$(5.3) \qquad \partial\tau(az, az) = z^*\partial\tau(a,a)z \quad \forall a \in \mathcal{M}, z \in \mathcal{Z},$$

where $\mathcal{Z}$ denotes the centre of $\mathcal{M}$. The converse holds when $\mathcal{M}'$ is abelian and k is normal.

Proof. The necessity of (5.3) is clear from the form τ must take according to (5.2). Conversely, suppose that $\mathcal{M}'$ is abelian (and so equals $\mathcal{Z}$), k is unital and normal and (5.3) holds, and let

$$\theta(a) = \begin{bmatrix} \tau(a) & \chi^\dagger(a) \\ \chi(a) & \nu(a) - \iota_0(a) \end{bmatrix} = \begin{bmatrix} \mathcal{L}(a) & \delta^\dagger(a)w \\ w^*\delta(a) & 0 \end{bmatrix}$$

be a representation of θ according to Theorem 3.2. Thus

$$(5.4) \qquad w^*\pi(a)w = a \otimes 1_{\mathsf{k}_0} \text{ and } \partial\mathcal{L}(a,a) = \delta(a)^*\delta(a),$$

with π normal. Also (5.3) with $a = 1$, and (5.4), imply that $\delta(z) = 0$ for $z \in \mathcal{Z} = \mathcal{M}'$, so that

$$(5.5) \qquad \delta(a)a' = \pi(a')\delta(a) \quad \forall a \in \mathcal{M}, a' \in \mathcal{M}'.$$

Now (5.4) also implies that w is isometric and, letting p be the orthogonal projection $ww^* \in \mathcal{M} \otimes \mathcal{B}(\mathsf{h})$,

$$p\pi(a)^*p^\perp\pi(a)p = p\pi(a^*a)p - p\pi(a^*)p\pi(a)p$$
$$= w(a^*a \otimes 1_{\mathsf{k}_0})w^* - w(a^* \otimes 1_{\mathsf{k}_0})(a \otimes 1_{\mathsf{k}_0})w^* = 0,$$

so p commutes with $\pi(\mathcal{M})$ and thus $\pi_1(a) = p^\perp\pi(a)p^\perp$ defines a normal representation π_1 of $\mathcal{M}$. Let

$$\pi_1(a) = V^*(a \otimes 1_{\mathsf{h}_1})V \text{ with } VV^* \in \mathcal{M}' \otimes \mathcal{B}(\mathsf{h}_1),$$

be its normal decomposition, and define a map $\gamma : \mathcal{M} \to \mathcal{B}(\mathfrak{h}; \mathfrak{h} \otimes \mathsf{h}_1)$ by $\gamma = V\delta$. Note that V satisfies

$$(5.6) \qquad (a \otimes 1_{\mathsf{h}_1})V = V\pi(a).$$

By (5.5), (5.6) and (5.4), γ satisfies

$$\gamma(a)a' = V\pi(a')\delta(a) = (a' \otimes 1_{\mathsf{h}_1})\gamma(a);$$
$$\gamma(ab) - \gamma(a)b - (a \otimes 1_{\mathsf{h}_1})\gamma(b) = V\pi(a)\delta(b) - (a \otimes 1_{\mathsf{h}_1})V\delta(b) = 0;$$
$$\gamma(a)^*\gamma(a) + \chi(a)^*\chi(a) = \delta(a)^*[V^*V + ww^*]\delta(a) = \partial\tau(a,a);$$

for $a, b \in \mathcal{M}$ and $a' \in \mathcal{M}'$. Thus γ is an ι_1-derivation satisfying $\gamma(\mathcal{M}) \subset \mathcal{M} \otimes \mathsf{h}_1$ and (5.1). The result follows. $\qquad\square$

Corollary 5.3. *A number/exchange-free Markov-regular normal CP unital cocycle on $\mathcal{B}(\mathfrak{h})$ has a number/exchange-free *-homomorphic dilation if and only if the creation component of its generator is an ι_0-derivation.*

Remark. Two consequences of the existence of a number/exchange-free *-homomorphic dilation for a Markov-regular CP contraction semigroup $\mathcal{P}$, with generator τ, are

(5.7a) $$\partial\tau(a, za) = \partial\tau(a, z)a + z\partial\tau(a, a)$$

(5.7b) $$\delta(a)z = 0 \text{ whenever } az = 0$$

where $z \in \mathcal{Z}$ and δ is an ι_1-derivation satisfying $\partial\tau(a, b) = \delta(a)^*\delta(b)$. When $\mathcal{M}$ is abelian (in which case $\mathcal{Z} = \mathcal{M}$) (5.7a) implies that

(5.7a)$'$ $\qquad\qquad \partial\tau$ is a derivation in its second argument.

In his study of *locality* for quantum dynamical semigroups ([**Sa2**]) Sauvageot (citing [**LeJ**], Section 1.5) notes that, in the commutative C^*-case, (5.7a)$'$ is equivalent to the locality of $\mathcal{P}$; that is

$$\lim_{t \searrow 0} t^{-1}\mathcal{P}_t f(x) = 0 \text{ whenever } f \text{ vanishes in a neighbourhood of } x.$$

This suggests an interesting link between the analytic property of locality and the quantum probabilistic property of number/exchange-free *-homomorphic dilatability, for noncommutative Markov semigroups. Note also that, in the commutative case, (5.7b) is locality for δ.

6. Unitary dilation.

In this section we consider contraction cocycles on a Hilbert space, and their stochastic dilation to unitary cocycles. We also apply this to construct an alternative form of dilation for unital CP cocycles on a von Neumann algebra.

A (*left*) *Markovian contraction cocycle* on the Hilbert space $\mathfrak{h}$ is a contraction process $(X_t)_{t \geq 0}$ on $\mathfrak{h}$ adapted to the Fock filtration and satisfying

$$X_{s+t} = X_s \sigma_s(X_t),$$

in which the right shift σ_s acts on $\mathcal{B}(\mathfrak{h} \otimes \Gamma_{\mathsf{k}})$ by

$$\sigma_s(T) = 1_s \otimes S_s T S_s^*,$$

where S_s is the right shift $\mathfrak{h} \otimes \Gamma_{\mathsf{k}} \to \mathfrak{h} \otimes \Gamma_{[s,\infty[,\mathsf{k}}$, 1_s is the identity operator on $\Gamma_{[0,s[,\mathsf{k}}$, and some natural identifications of tensor products are invoked. The Markov semigroup of X is defined by $P_t = \mathbb{E}[X_t] = E^*X_t E$ $(t \geq 0)$. The cocycle X is called *Markov-regular* if P is norm continuous $\mathbb{R}_+ \to \mathcal{B}(\mathfrak{h})$. The counterpart to Theorem 1.1 is:

Theorem 6.1 (**[LW2]**)**.** *Let X be a contraction process on the Hilbert space $\mathfrak{h}$, with separable noise dimension space k_0. Then the following are equivalent*:

  (i) *X is a Markov-regular cocycle.*
  (ii) *X weakly satisfies a QS differential equation of the form*

$$(6.1) \qquad\qquad dX_t = X_t F_\beta^\alpha \, d\Lambda_\alpha^\beta(t), \quad X_0 = 1,$$

   for an operator matrix $F \in \mathrm{M}_D(\mathcal{B}(\mathfrak{h}))$.

In this case X satisfies the equation strongly, and F defines a bounded operator on $\mathfrak{h} \otimes \widehat{\mathsf{k}_0}$. Moreover, for a von Neumann algebra $\mathcal{M}$ acting on $\mathfrak{h}$, $X_t \in \mathcal{M} \otimes \mathcal{B}_{\mathsf{k}_0}$ for all $t \geq 0$ if and only if $F \in \mathcal{M} \otimes \mathcal{B}(\widehat{\mathsf{k}_0})$.

Remark. A (unique) strong solution to (6.1) exists whenever $[F_\beta^\alpha]$ defines a bounded operator F on $\mathfrak{h} \otimes \widehat{\mathsf{k}}$ (**[LW1]**, Theorem 7.1), although the solution may be unbounded. Following (1.1) such F will be written in block matrix form as $\begin{bmatrix} A & B \\ C & D \end{bmatrix}$ with $A \in \mathcal{B}(\mathfrak{h})$, $B, C^* \in \mathcal{B}(\mathfrak{h} \otimes \mathsf{k}; \mathfrak{h})$ and $D \in \mathcal{B}(\mathfrak{h} \otimes \mathsf{k})$.

The case where X is unitary was established in **[HuL]** and **[Mo1]**. Weakly differentiable Markovian contraction cocycles were shown to satisfy a QS differential equation in **[AJL]** and **[Fag]**. An interesting characterisation of strongly continuous unitary Markovian cocycles was obtained in **[Jou]**, which also contains an example of such a cocycle which fails to satisfy a QS differential equation.

Propositions 7.5 and 7.6 of **[LW1]** may be stated as follows, using the representation of nonnegative operator matrices given in Lemma 2.1 once more:

Theorem 6.2. *Let X be a process on the Hilbert space $\mathfrak{h}$ with separable noise dimension space k_0, weakly satisfying a QS differential equation of the form (6.1). Then the following equivalences hold*:

 (ai) *X is a contraction process.*
 (aii) *F is bounded with block matrix form*

$$F = \begin{bmatrix} iH - \frac{1}{2}(M^*M + B^2) & BVS - M^*W \\ M & W - 1 \end{bmatrix}$$

   where $H = H^*, B \geq 0$, $\|V\|, \|W\| \leq 1$ and $S = (1 - W^*W)^{1/2}$.
(aiii) *F is bounded with block matrix form*

$$F = \begin{bmatrix} iH - \frac{1}{2}(LL^* + C^2) & -L \\ WL^* - RV'C & W - 1 \end{bmatrix}$$

   where $H = H^*$, $C \geq 0, \|V'\|, \|W\| \leq 1$ and $R = (1 - WW^*)^{1/2}$.
 (bi) *X is isometric.*
 (bii) *In (aii) W is isometric and $B = 0$.*

(ci) X *is coisometric.*

(cii) *In* (aiii) W *is coisometric and* $C = 0$.

(di) X *is unitary*

(dii) *In* (aii) W *is unitary and* $B = 0$.

(diii) *In* (aiii) W *is unitary and* $C = 0$.

The representation (aii) *is unique provided that* V *satisfies* $\mathrm{Ker}\, V \supset \mathrm{Ker}\, S$ *and* $\mathrm{Ran}\, V \subset \overline{\mathrm{Ran}}\, B$, *which may be easily arranged. Uniqueness of the representation* (aiii) *may be similarly arranged.*

Remark. Thus associated with a Markov-regular operator contraction cocycle X is a unique octet $(H, W, (M, B, V), (L, C, V'))$, and conversely, X is determined by either one of the two parameterisations (H, W, M, B, V) or (H, W, L, C, V').

Theorem 6.3. *Every Markov-regular contraction cocycle on a Hilbert space, with separable noise dimension space, admits a unitary stochastic dilation.*

Proof. Let X be a Markov-regular contraction cocycle on $\mathfrak{h}$, with separable noise dimension space k_0. By Theorems 6.1 and 6.2, X has a stochastic generator of the form

$$\begin{bmatrix} K & -Q \\ N & W - 1 \end{bmatrix},$$

where $K = iH - \frac{1}{2}(N^*N + B^2)$, $Q = N^*W - BVS$, $H = H^*$, $B \geq 0$, $\|W\|, \|V\| \leq 1$ and $S = (1 - W^*W)^{1/2}$.

Set $\mathsf{k} = \mathsf{k}_0 \oplus \mathsf{k}_1 \oplus \mathsf{k}_2$, where k_1 and k_2 are to be determined, and let $G \in \mathcal{B}(\mathfrak{h} \otimes \widehat{\mathsf{k}})$ with block matrix form

$$\begin{bmatrix} K & -L \\ M & U - 1 \end{bmatrix}$$

in which

(6.2a) $U^*U = UU^* = 1, \quad M^*M = N^*N + B^2 \quad \text{and} \quad L = M^*U.$

Then G generates a unitary cocycle by Theorem 6.2, and by the operator process analogue of Lemma 1.2 this cocycle is a stochastic dilation of X if and only if

(6.2b) $M^0 = N, \quad L_0 = Q \quad \text{and} \quad U_0^0 = W.$

Solutions of the constraints (6.2) are obtained by taking $\mathsf{k}_1 = \mathsf{k}_0, \mathsf{k}_2 = \mathbb{C}$,

$$M = \begin{bmatrix} N \\ -V^*B \\ M_2 \end{bmatrix}, \quad L = \begin{bmatrix} Q & L_1 & M_2^* \end{bmatrix}, \quad \text{and} \quad U = \begin{bmatrix} W & R & 0 \\ S & -W^* & 0 \\ 0 & 0 & 1 \end{bmatrix},$$

where $R = (1 - WW^*)^{1/2}$, $L_1 = BVW^* + N^*R$, and $M_2 \in \mathcal{B}(\mathfrak{h})$ is chosen so that $M_2^*M_2 = B(1 - VV^*)B$. $\qquad \square$

Remarks.　　(i) If X is affiliated to a von Neumann algebra $\mathcal{M}$, then it has a unitary dilation which is affiliated to $\mathcal{M}$ also.

(ii) If $B = 0$, in particular if X is isometric (but not unitary), then $M_2 = 0$ and we may take $\mathsf{k}_1 = \mathsf{k}_0$ and $\mathsf{k}_2 = \{0\}$, giving the dilation generator

$$
G = \begin{bmatrix} iH - \frac{1}{2}N^*N & -N^*W & -N^*R \\ N & W - 1 & R \\ 0 & S & -W^* - 1 \end{bmatrix},
$$

with R and S as above.

(iii) If W is unitary (but $B \neq 0$) then $V = 0$ and the simplest solution is $\mathsf{k}_1 = \{0\}, \mathsf{k}_2 = \mathbb{C}$ and

$$
G = \begin{bmatrix} iH - \frac{1}{2}(N^*N + B^2) & -N^*W & iB \\ N & W - 1 & 0 \\ iB & 0 & 0 \end{bmatrix}.
$$

(iv) To see what is being stochastically generalised here, let $\mathsf{k}_0 = \{0\}$ so that we have a contraction semigroup on $\mathfrak{h}$. Then (iii) applies, giving

$$
G = \begin{bmatrix} iH - \frac{1}{2}B^2 & iB \\ iB & 0 \end{bmatrix},
$$

and the dilation is effected by the solution U of the stochastic differential equation

$$
dU_t = U_t \left[iB \, dQ_t + \left(iH - \frac{1}{2}B^2 \right) dt \right]
$$

where $Q = (A_t + A_t^\dagger)_{t \geq 0}$ is a classical Brownian motion. When the operators B and H commute it is given explicitly by

$$
U_t = e^{i(B \otimes Q_t + tH \otimes I)}.
$$

(v) Using time-reversal techniques, or by taking adjoints, Markov-regular *right* contraction cocycles are equally seen to have unitary stochastic dilations.

We end this section with an alternative form of dilation for unital CP cocycles.

Theorem 6.4. *Every normal Markov-regular completely positive unital co-cycle k, on a von Neumann algebra, with separable noise dimension space k_0 and initial space $\mathfrak{h}$, enjoys a factorisation of the following form:*

$$
(6.3) \qquad\qquad \widetilde{k}_t = \mathbb{E}_1 \circ \mathrm{ad}\, U_t \circ \iota
$$

in which $\widetilde{k}_t(a) = k_t(a) \otimes 1$ on $\mathfrak{h} \otimes \Gamma_{\mathsf{k}_1}$, $\iota(a) = a \otimes 1$ on $\mathfrak{h} \otimes \Gamma_{\mathsf{k}_1 \oplus \mathsf{k}_1}$, $\mathsf{k}_1 \supset \mathsf{k}_0$ is separable and U is a Markov-regular unitary cocycle. If k_0 is infinite dimensional then we may take $\mathsf{k}_1 = \mathsf{k}_0$, so that $\widetilde{k} = k$.

Proof. Theorem 4.5 of [**GLW**] ensures the existence of a separable Hilbert space k_1 containing k_0, and a Markov-regular coisometry cocycle X with noise dimension space k_1 such that $k_t(a) \otimes 1 = X_t(a \otimes 1)X_t^*$ on $\mathfrak{h} \otimes \Gamma_{k_1}$. Let k^- denote the Markovian cocycle on $\mathcal{B}(\mathfrak{h})$ given by the same formula. The stochastic generators of X and k^- have the respective forms

$$(6.4) \qquad \widehat{F} = \begin{bmatrix} iH - \frac{1}{2}M^*M & -M^* \\ W^*M & W^* \end{bmatrix}, \quad \widehat{\theta}(a) = \begin{bmatrix} \tau(a) & \delta^\dagger(a)W \\ W^*\delta(a) & W^*\iota_1(a)W \end{bmatrix}$$

where $H = H^*, W^*W = 1, \iota_1(a) = a \otimes 1$ on $\mathfrak{h} \otimes k_1, \delta = \delta_{M,\iota_1}$ and $\tau = \mathcal{L}_{M,\iota_1,H}$. If X is unitary then (6.3) holds with $U_t = X_t \otimes 1$. If X is nonunitary then, by Theorem 6.2, W^* is nonisometric and we let U be the unitary stochastic dilation of X whose generator is defined by

$$\widehat{G} = \begin{bmatrix} iH - \frac{1}{2}M^*M & -M^* & 0 \\ W^*M & W^* & 0 \\ RM & R & -W \end{bmatrix}$$

where $R = (1 - WW^*)$, and set $j_t^- = \operatorname{ad} U_t : a \mapsto U_t(a \otimes 1)U_t^*$. Then the stochastic generator of j^- is given by

$$\phi(a) = \iota(a)G^* + G\iota(a) + G\Delta(a)G^*,$$

where $\Delta(a) = a \otimes \Delta$ and Δ is the orthogonal projection in $\mathcal{B}(\widehat{k})$ with range $k = k_1 \oplus k_1$, so that

$$\widehat{\phi}(a) = \begin{bmatrix} \tau(a) & \delta^\dagger(a)W & \delta^\dagger(a)R \\ W^*\delta(a) & W^*\iota_1(a)W & W^*\iota_1(a)R \\ R\delta(a) & R\iota_1(a)W & R\iota_1(a)R + W\iota_1(a)W^* \end{bmatrix}.$$

Invoking Lemma 1.2 once more, comparison with (6.4) shows that j^- is a stochastic dilation of k^-, and the result follows. $\qquad\square$

Remark. This need not be a stochastic dilation of $\widetilde{k}$ in our sense, since U need not be affiliated to $\mathcal{M}$.

7. Application to classical probability.

Two areas of classical probability where ideas from the theory of CP-valued quantum processes might be applied are filtering theory and measure-valued diffusion. Indeed the Zakai equation (see e.g., [**KaK**]), governing the conditional distribution of a signal process at time t given the σ-algebra of an observed process up to time t, was a motivation for Belavkin to consider quantum filtering from the point of view of QS differential equations ([**Be1**]). Below we give a rough outline of how one might view measure-valued diffusions as conditioned classical processes on the underlying state space.

Consider a compact Hausdorff space X. Let $\mathcal{P}$ denote the set of regular Borel probability measures on X, equipped with the topology of weak

convergence, and let $\mathcal{A}$ denote the unital C^*-algebra of continuous complex-valued functions on X. Also let $L^2(\mathbb{P})$ be the L^2-space of the probability space $(\Omega, \mathfrak{F}, \mathbb{P})$ of a family $P^1, \ldots, P^m$ of independent Poisson processes with respective intensities $\lambda_1, \ldots, \lambda_m$. Finally let $\mu := (\mu_t^x : \Omega \to \mathcal{P})_{x \in X, t \geq 0}$ be a family of maps satisfying suitable measurability conditions, the condition that, for each $t \geq 0$ and $f \in \mathcal{A}$, the map $x \mapsto \langle f, \mu_t^x(\omega) \rangle := \int f(y) \mu_t^x(\omega)(dy)$ is continuous for almost all $\omega \in \Omega$, and also the following stochastic differential equation:

$$(7.1) \qquad d\langle f, \mu_t^x \rangle = \langle \alpha_0(f), \mu_t^x \rangle \, dt + \sum_{i=1}^{m} \langle \alpha_i(f), \mu_t^x \rangle \, dP_t^i, \quad \mu_0^x = \delta_x,$$

where $\alpha_0, \ldots, \alpha_m$ are bounded linear maps on $\mathcal{A}$ such that $\alpha_i(\overline{f}) = \overline{\alpha_i(f)}$ and $\alpha_i(1) = 0$. Thus (μ_t^x) is a measure-valued diffusion.

In order to cast this in a QS form, first let $\mathcal{M}$ be the universal enveloping algebra of $\mathcal{A}$ and let $\mathfrak{h}$ be the Hilbert space on which it acts. Then each α_i extends to a bounded normal operator on $\mathcal{M}$ — which we denote by α_i^{**}.

Under the natural identification of $L^2(\mathbb{P})$ with $\Gamma(L^2(\mathbb{R}_+; \mathbb{C}^m))$, the operator of multiplication by P_t^i corresponds to the following combination of fundamental quantum processes:

$$(7.2) \qquad\qquad N_t^i(t) + \sqrt{\lambda_i}(A_i(t) + A_i^\dagger(t)) + \lambda_i t$$

([**Mey**], p. 74). Let $\overline{k}$ be the Markovian cocycle on $\mathcal{M}$ generated by θ where

$$\theta_0^0 = \alpha_0^{**} + \sum_{i=1}^{m} \lambda_i \alpha_i^{**}, \theta_0^i = \theta_i^0 = \sqrt{\lambda_i} \alpha_i^{**}, \text{ and } \theta_j^i = \delta_j^i \alpha_i^{**}.$$

Then $\overline{k}$ is normal, CP and unital. Comparison with (7.1) and (7.2) shows that for $f \in \mathcal{A}$, viewed as a subalgebra of $\mathcal{M}$, $k_t(f)$ corresponds to the operator of multiplication by the function $F_t : \Omega \to \mathcal{A} \subset \mathcal{M}$ given by $F_t(\omega) = \langle f, \mu_t(\omega) \rangle$.

Suppose now that $\overline{k}$ has a unital *-homomorphic dilation $\overline{\jmath}$. Let j_t be the restriction of $\overline{\jmath}_t$ to $\mathcal{A}$ then the C^*-algebra generated by $\{j_t(f) : t \geq 0, f \in \mathcal{A}\}$ is abelian ([**Par**], Theorem 28.8). Letting Σ be its spectrum, our process may be viewed as consisting of unital *-homomorphisms $j_t : C(X) \to C(\Sigma)$. By Gelfand theory (specifically the Banach-Stone Theorem) there are continuous maps $\xi_t : \Sigma \to X$ such that $j_t(f) = f \circ \xi_t$. In this way the dilation of k may be viewed as a lifting of the measure-valued diffusion μ to a "process" ξ taking values in the underlying state space.
