

Engel structures with trivial characteristic foliations

JIRO ADACHI

Abstract Engel structures on $M \times S^1$ and $M \times I$ are studied in this paper, where M is a 3-dimensional manifold. We suppose that these structures have characteristic line fields parallel to the fibres, S^1 or I . It is proved that they are characterized by contact structures on the cross section M , the twisting numbers, and Legendrian foliations on both ends $M \times \partial I$ in the case of $M \times I$.

Keywords Engel structure, prolongation, Legendrian foliation

0 Introduction

In any category of geometry, exotic structures are interesting objects to study. In addition, the classification is an important problem. Engel structures are largely dominated by the characteristic foliations. This paper is devoted to the characterization of Engel structures on $M \times S^1$ and $M \times I$, where M is a 3-dimensional manifold, with the same characteristic foliation as the standard Engel structure.

A maximally non-integrable distribution of rank 2 on a 4-dimensional manifold is called an *Engel structure* (see Section 1.1 for the precise definition). Engel structures have no local invariant, similarly to contact and symplectic structures. There exists a local normal form, written as a kernel of two differential 1-forms,

$$dy - z \cdot dx = 0, \quad dz - w \cdot dx = 0, \quad (0.1)$$

where (x, y, z, w) is a coordinate system. Further, it is known that this property occurs only on line fields, contact structures, even-contact structures, and Engel structures, among regular tangent distributions on manifolds (see [M1], [VG]). An *even-contact structure* is a hyperplane field on an even dimensional manifold with maximal non-integrability. The fact above indicates the importance of the study of Engel structures. However, different from contact structures, global stability does not hold for Engel structures, that is, the Gray type

theorem does not hold. There exists a line field $\mathcal{L}(\mathcal{D}^2)$, which is canonically defined by a given Engel structure \mathcal{D} , especially by an even-contact structure $\mathcal{D}^2 := \mathcal{D} + [\mathcal{D}, \mathcal{D}]$ (see Section 1.1). It is called the *characteristic line field* of \mathcal{D} or \mathcal{D}^2 . The foliation $L(\mathcal{D}^2)$, whose leaves are integral curves of the characteristic line fields, is called the *characteristic foliation* of \mathcal{D} or \mathcal{D}^2 . This is the obstruction to global stability. It is proved by A. Golubev and R. Montgomery in [Go] and [M2] that a deformation of an Engel structure is realized by an isotopy if it fix the characteristic line field. If the above two differential 1-forms (0.1) are defined globally on \mathbb{R}^4 , the obtained Engel structure is called the *standard* Engel structure on \mathbb{R}^4 . Let \mathcal{D}_{st} denote it. The standard Engel structure has its characteristic line field spanned by a vector field in the w direction, $\mathcal{L}(\mathcal{D}_{st}^2) = \text{Span}(\partial/\partial w)$. V. Gershkovich constructs in [Ge] examples of Exotic Engel structures on \mathbb{R}^4 with periodic orbits in their characteristic line fields. To study exotic Engel structures with the same characteristic line field as the standard Engel structure is a motivation for this paper.

In order to state the results of this paper, we prepare some basic notions. Let ξ be a contact structure on a 3-dimensional manifold M . Let us construct a new 4-dimensional manifold $\mathbb{P}(\xi)$ from ξ . A contact structure ξ is a certain 2-plane field. Then the manifold $\mathbb{P}(\xi)$ is obtained by the fibrewise projectivization of ξ : $\mathbb{P}(\xi) = \cup_{p \in M} \mathbb{P}(\xi_p)$, where $\mathbb{P}(\xi_p)$ is the projectivization of the tangent plane ξ_p . This manifold has a structure of the S^1 -bundle over M , because each fibre is equivalent to S^1 : $\mathbb{P}(\xi_p) \cong \mathbb{R}P^1 \cong S^1$. We can regard a point $l \in \mathbb{P}(\xi_p)$ of a fibre as a line on the plane ξ_p through the origin. A 2-plane $\mathcal{D}(\xi)_{(p,l)}$ at a point $(p, l) \in \mathbb{P}(\xi)$ is induced by the pull back of a line $l \subset \mathbb{P}(\xi_p)$ by the projection $\pi: \mathbb{P}(\xi) \rightarrow M$. Then we obtain a 2-plane field $\mathcal{D}(\xi)$ on $\mathbb{P}(\xi)$. It is known that this 2-plane field $\mathcal{D}(\xi)$ is an Engel structure on $\mathbb{P}(\xi)$ (see [M2]). This Engel manifold $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ is called a *prolongation* of a contact 3-manifold (M, ξ) (see Section 1.2 for the definition). Furthermore, we consider its fibrewise n -fold covering and the corresponding Engel structure. Let $(\mathbb{P}_n(\xi), \mathcal{D}_n(\xi))$ denote them. We regard $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ as $(\mathbb{P}_1(\xi), \mathcal{D}_1(\xi))$, if necessary. We note that the prolonged manifold $\mathbb{P}_n(\xi)$ is diffeomorphic to $M \times S^1$ if the given contact structure ξ is trivial as plane field. There is a canonical identification $\psi_n: \mathbb{P}_n(\xi) \rightarrow M \times S^1$ in this case. According to this identification, we obtain an Engel structure $\bar{\mathcal{D}}_n(\xi) := (\psi_n)_* \mathcal{D}_n(\xi)$ on $M \times S^1$ from a contact structure ξ on M and a natural number $n \in \mathbb{N}$. Prolongations and deprolongations are discussed in Section 1.2.

In this paper, Engel structures on $M \times S^1$ and $M \times I$ with trivial characteristic foliations are investigated. We say a characteristic foliation L is *trivial* if it is isotopic to a foliation which consists of leaves $\{pt\} \times S^1 \subset M \times S^1$ or $\{pt\} \times I \subset$

$M \times I$. In the following, we suppose that these isotopies have been applied. Namely, we assume in the following that a trivial characteristic foliation consists of leaves $\{pt\} \times S^1$ or $\{pt\} \times I$. In this case, we can define invariants for Engel structures. Let \mathcal{D} be an Engel structure on $M \times S^1$ with a trivial characteristic foliation. An Engel structure, as a 2–plane field, is spanned by the characteristic line field and a line field twisting along leaves of the characteristic foliation (see Section 1.1). Now each leaf of characteristic foliation is a fibre $\{pt\} \times S^1 \subset M \times S^1$. Then we can define an invariant, the *twisting number* $\text{tw}(\mathcal{D})$ of \mathcal{D} , by counting the rotation along a leaf with respect to a fixed framing of ξ . Similarly we, define the *minimal twisting number* $\text{tw}_-(\mathcal{D})$ for Engel structures on $M \times I$. (see Section 1.3 for the definitions.)

Next, we consider the induced Legendrian foliations. Let \mathcal{D} be an Engel structure on $M \times S^1$ or $M \times I$ with a trivial characteristic foliation $L(\mathcal{D}^2)$. Let us identify cross sections of $M \times S^1$ and $M \times I$ with M itself by the standard projection. This projection is the projection along the characteristic foliation $L(\mathcal{D}^2)$ too. We note that this M is transverse to the characteristic foliation $L(\mathcal{D}^2)$. It is known that the even-contact structure \mathcal{D}^2 induce a contact structure $\xi(\mathcal{D}^2)$ on M (see [M2] and [Ge]). It does not depend on the choice of the cross section (see Section 1.2). Similarly the Engel distribution \mathcal{D} induce an 1–dimensional foliation $\mathcal{F}(M, \mathcal{D})$ on M by the integral of the line field defined by the intersection of \mathcal{D} and M . We note that the leaves of this foliation $\mathcal{F}(M, \mathcal{D})$ are tangent to the induced contact structure $\xi(\mathcal{D}^2)$ everywhere. Curves in contact 3–manifolds, which are tangent to the contact structures everywhere, are called *Legendrian curves*. We call this foliation $\mathcal{F}(M, \mathcal{D})$ the *induced Legendrian foliation*.

Now, we are ready to state the results of this paper. First, we consider Engel structures on $M \times S^1$ with trivial characteristic foliations.

Theorem 1 (1) *Let ξ, ζ be parallelizable contact structures, that is, they have global framings. If the prolonged Engel structures $\bar{\mathcal{D}}(\xi)$ and $\bar{\mathcal{D}}(\zeta)$ are isotopic preserving the characteristic foliation, then the contact structures ξ and ζ are isotopic.*

(2) *For any Engel structure \mathcal{D} on a 4–dimensional manifold $M \times S^1$ with a trivial characteristic foliation, there exist a contact structure ξ on M and a natural number $n \in \mathbb{N}$, for which the n –fold prolonged Engel structure $\bar{\mathcal{D}}_n(\xi)$ of ξ on $M \times S^1$ is isotopic to \mathcal{D} .*

In other words, this theorem implies the following.

Corollary 1 *Engel structures on $M \times S^1$ with trivial characteristic foliations are characterized, up to isotopies, by isotopy classes of contact structures on M and the twisting number $\text{tw}(\mathcal{D}) \in \mathbb{N}$.*

We note that we can construct an Engel structure $\bar{\mathcal{D}}_n(\xi)$ on $M \times S^1$ for any isotopy class $[\xi]$ of contact structures on M which are trivial as plane fields, and a natural number $n \in \mathbb{N}$.

Next, we show that Engel structures on $M \times I$ with the trivial characteristic foliation are determined by the induced contact structures, the minimal twisting numbers, and the induced Legendrian foliations on both ends $M \times \partial I$.

Theorem 2 (1) *Let \mathcal{D} and $\tilde{\mathcal{D}}$ be Engel structures on $M \times I$ with the trivial characteristic foliations. If they have the same induced contact structure, induced Legendrian foliations on both ends $M \times \partial I$, and minimal twisting number, then they are isotopic relative to the ends.*

(2) *Let ξ be a parallelizable contact structure on a 3-manifold M , $(\mathcal{F}_0, \mathcal{F}_1)$ a pair of Legendrian foliations on (M, ξ) , and $n \in \mathbb{Z}_{\geq 0}$ a non-negative integer. Then there exists an Engel structure $\mathcal{D} = \mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ on $M \times I$, which has the induced contact structure $\xi(\mathcal{D}) = \xi$, the induced Legendrian foliations $\mathcal{F}(M \times \{i\}, \mathcal{D}) = \mathcal{F}_i, i = 0, 1$, and the minimal twisting number $\text{tw}(\mathcal{D}) = n$.*

This theorem implies the following.

Corollary 2 *Engel structures on $M \times I$ with the trivial characteristic foliation are determined by the induced contact structures and the induced Legendrian foliations on both ends $M \times \partial I$ and the minimal twisting numbers.*

This paper was established while the author was visiting at Stanford University and the University of Pennsylvania. He would like to express his gratitude to Professor Yakov Eliashberg and Professor John Etnyre for some discussions and the hospitality. This work was partially supported by JSPS Research Fellowship for Young Scientists.

1 Preliminary

1.1 Definitions and important properties.

Let W be a 4-dimensional manifold. A *distribution* of rank 2 or a *2-plane field* \mathcal{D} on W is a distribution of 2-dimensional tangent planes $\mathcal{D}_p \subset T_p W, p \in W$.

It is considered as a rank 2 subbundle of the tangent bundle TW . We can think of \mathcal{D} as a locally free sheaf of smooth vector fields on M . Let $[\mathcal{D}, \mathcal{D}]$ denote the sheaf generated by all Lie brackets $[X, Y]$ of vector fields X, Y on M , which are cross sections of \mathcal{D} . We set $\mathcal{D}^2 := \mathcal{D} + [\mathcal{D}, \mathcal{D}]$ and $\mathcal{D}^3 := \mathcal{D}^2 + [\mathcal{D}, \mathcal{D}^2]$. The Engel structure is defined as follows.

Definition A distribution \mathcal{D} of rank 2 on a 4-dimensional manifold W is called an *Engel structure* if it satisfies,

$$\dim \mathcal{D}^2 = 3, \quad \dim \mathcal{D}^3 = 4, \quad (1.1)$$

at any point $p \in W$.

We note that \mathcal{D}^2 is a distribution of rank 3 and \mathcal{D}^3 is the tangent bundle TW itself, if \mathcal{D} is an Engel structure. This corank 1 distribution \mathcal{D}^2 is an even-contact structure on W . Let \mathcal{E} denote it. An *even-contact structure* is, by definition, a corank 1 distribution \mathcal{E} on an even-dimensional manifold, which is defined, at least locally, by 1-form θ with a property that $\theta \wedge (d\theta)^{n/2-1}$ is never-vanishing $(n-1)$ -form, where n is the dimension of the manifold. An even-contact structure \mathcal{E} on a 4-manifold W has a characteristic 1-dimension. We define a rank 1 subdistribution $\mathcal{L}(\mathcal{E})$ of \mathcal{E} by $[\mathcal{L}(\mathcal{E}), \mathcal{E}] \subset \mathcal{E}$. In other words, it is a maximal integrable subdistribution of \mathcal{E} . In this case, its rank is 1. It is called the *characteristic line field* of $\mathcal{E} = \mathcal{D}^2$ or sometimes of \mathcal{D} . We call the 1-dimensional foliation obtained by integrating the characteristic line field the *characteristic foliation* of \mathcal{D}^2 or \mathcal{D} . We note that an Engel structure \mathcal{D} should include its characteristic line field to satisfy the Engel condition (1.1).

Contact structures are sometimes described in terms of contact forms. Similarly, Engel structures are described in terms of pairs of differential 1-forms. A pair of 1-forms (α, β) on a 4-manifold W is called an *Engel pair of 1-forms* if it satisfies the following three conditions,

- (1) $\alpha \wedge \beta \wedge d\alpha$ never vanishes,
- (2) $\alpha \wedge \beta \wedge d\beta \equiv 0$,
- (3) $\beta \wedge d\beta$ is a never-vanishing 3-form.

It is known that the distribution $\mathcal{D} := \{\alpha = 0, \beta = 0\}$ defined by an Engel pair of 1-forms is an Engel structure (see [Ge]). Under these conditions above, the 1-form β defines an even-contact distribution as $\mathcal{D}^2 = \{\beta = 0\}$, and the characteristic line field $\mathcal{L}(\mathcal{D}^2)$ is defined as a kernel of the 3-form $\beta \wedge d\beta$. For an even-contact distribution $\mathcal{E} = \{\beta = 0\}$, a vector field X_0 is called the *characteristic vector field* of \mathcal{E} , if it satisfies $X_0 \lrcorner \Omega = \beta \wedge d\beta$ for some volume

form Ω on W . We note that it generates the characteristic line field and foliation of \mathcal{E} .

At the end of this section, we introduce important properties of Engel structures. They play important roles in the proof of Theorems. The following theorem is proved by R. Montgomery in [M2], after E. Cartan's theory.

Theorem 1.1 *Let $\mathcal{D}_0, \mathcal{D}_1$ be Engel structures defined near an embedded 3-manifold M in a 4-manifold W . We assume that their characteristic foliation $L(\mathcal{D}_i^2)$, $i = 0, 1$, are transverse to M , and that these Engel structures \mathcal{D}_i , $i = 0, 1$, have the same induced Legendrian foliation on M : $\mathcal{F}(M, \mathcal{D}_0) = \mathcal{F}(M, \mathcal{D}_1)$. Then they are locally isotopic along $M \subset W$.*

A slight generalization of this theorem is shown in [A]. The case where the embedded 3-manifold is not transverse to the characteristic foliation is considered in [A]. The following theorem is proved in [M2] and [Go]. It is well known that contact structures on a closed orientable 3-manifold are isotopic if they are homotopic among contact structures (the Gray Theorem). The following theorem is the Gray type theorem for Engel structures.

Theorem 1.2 *Let \mathcal{D}_t , $t \in [0, 1]$, be a family of Engel structures on a closed orientable 4-manifold W . We assume that it has the fixed characteristic foliation: $L(\mathcal{D}_t^2) \equiv L$. Then there exists a family $\phi_t: W \rightarrow W$, $t \in [0, 1]$, of global diffeomorphisms which satisfies $(\phi_t)_*\mathcal{D}_t = \mathcal{D}_0$, $(\phi_t)_*L = L$.*

1.2 Prolongation procedures of contact manifolds.

The notion of prolongation is introduced by E. Cartan in the theory of exterior differential systems (see [C], [BCG3]). We consider the prolongations of contact structures on 3-manifolds. Let ξ be a contact structure on a 3-manifold M , namely a certain 2-plane field. We construct a new 4-dimensional manifold from ξ by fibrewise projectivizations,

$$\mathbb{P}(\xi) := \bigcup_{p \in M} \mathbb{P}(\xi_p),$$

where $\mathbb{P}(\xi_p)$ is a projectivization of a tangent plane ξ_p . A point of $\mathbb{P}(\xi)$ can be regarded as a line l in the contact plane ξ_p through the origin. The constructed 4-manifold $\mathbb{P}(\xi)$ has a structure of a circle bundle over M . Let $\pi: \mathbb{P}(\xi) \rightarrow M$ be its projection. This 4-manifold is endowed with a 2-plane field $\mathcal{D}(\xi)$ induced naturally as follows. We define 2-plane $\mathcal{D}(\xi)_q \subset T_q(\mathbb{P}(\xi))$ at $q = (p, l) \in \mathbb{P}(\xi)$.

A point $q = (p, l) \in \mathbb{P}(\xi)$ is regarded as a pair of a point $p \in M$ and a tangent line $l \subset \xi_p \subset T_pM$. Then we set $\mathcal{D}(\xi)_q := (d\pi^{-1})_q l$. Thus we obtain a 2-plane field $\mathcal{D}(\xi)$ on a 4-manifold $\mathbb{P}(\xi)$. We call this $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ the *prolongation* of a contact structure ξ on a 3-manifold M . It is known that the prolongation $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ is an Engel manifold (see [M2]). We note that the prolonged manifold $\mathbb{P}(\xi)$ is diffeomorphic to $M \times S^1$ if the contact structure ξ belongs to the trivial class as plane fields. In this paper we consider this case especially.

Furthermore, we consider some variants of prolongations. Let $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ be the prolongation of a contact structure ξ on a 3-manifold M . We define a new 4-manifold $\mathbb{P}_n(\xi)$ by fibrewise n -fold covering of $\mathbb{P}(\xi)$,

$$\mathbb{P}_n(\xi) := \bigcup_{p \in M} \mathbb{P}_n(\xi_p),$$

where $\mathbb{P}_n(\xi_p)$ is an n -fold covering space of $\mathbb{P}(\xi_p)$. Let $\varphi_n: \mathbb{P}_n(\xi) \rightarrow \mathbb{P}(\xi)$ be a fibrewise covering bundle mapping. We obtain a corresponding Engel structure $\mathcal{D}_n(\xi)$ on $\mathbb{P}_n(\xi)$: $(\varphi_n)_* \mathcal{D}_n(\xi) = \mathcal{D}(\xi)$. This pair $(\mathbb{P}_n(\xi), \mathcal{D}_n(\xi))$ is called the *n -fold prolongation* of a contact structure on a 3-manifold M . According to this notation, we have $(\mathbb{P}(\xi), \mathcal{D}(\xi)) = (\mathbb{P}_1(\xi), \mathcal{D}_1(\xi))$. When the given contact structure ξ on a 3-manifold M is trivial as plane fields, $\mathbb{P}_n(\xi)$ is diffeomorphic to $M \times S^1$ for any $n \in \mathbb{N}$. Let V_0, V_1 be vector fields on M spanning ξ : $\xi = \text{Span}\langle V_0, V_1 \rangle$. There is a canonical identification $\psi_n: M \times S^1 \rightarrow \mathbb{P}_n(\xi)$ defined as follows,

$$\psi_n: (p, \theta) \mapsto \left(p, l = \left[(V_0)_p \cdot \cos\left(\frac{n\theta}{2}\right) + (V_1)_p \cdot \sin\left(\frac{n\theta}{2}\right) \right] \right),$$

where $l \in \mathbb{P}_n(\xi_p)$ is a line in ξ_p defined by a vector field $(V_0)_p \cdot \cos(n\theta/2) + (V_1)_p \cdot \sin(n\theta/2)$. Then we obtain a corresponding Engel structure on $M \times S^1$ by setting $\tilde{\mathcal{D}}_n(\xi) := (\psi_n^{-1})_* \mathcal{D}_n(\xi)$, $n = 1, 2, 3, \dots$. In addition, we consider a fibrewise universal covering of a prolongation $\mathbb{P}(\xi)$, and let $(\tilde{\mathbb{P}}(\xi), \tilde{\mathcal{D}}(\xi))$ denote it.

Next, we consider the deprolongation procedure, the inverse of the prolongation, in a sense. Similarly to the above, we consider deprolongation of Engel structures especially. Let \mathcal{D} be an Engel structure on a 4-manifold W , $\mathcal{E} := \mathcal{D}^2$ its even-contact structure, and $L(\mathcal{E})$ its characteristic foliation. We consider the leaf space $W/L(\mathcal{E})$ and its projection $\pi: W \rightarrow W/L(\mathcal{E})$. The foliation $L(\mathcal{E})$ is said to be *nice*, according to [M2], if $W/L(\mathcal{E})$ is a smooth 3-manifold and π is a submersion. We suppose here that $L(\mathcal{E})$ is nice. We set $\xi(\mathcal{E}) := \pi_* \mathcal{E}$. It is a 2-plane field on $W/L(\mathcal{E})$, which is well defined because the characteristic vector field X_0 , along $L(\mathcal{E})$, preserves the even-contact structure \mathcal{E} . In

fact, the even-contact structure $\mathcal{E} = \mathcal{D}^2$ is determined by the second 1-form β of the Engel pair of 1-forms (α, β) . Since the characteristic vector field X_0 is defined so that $X_0 \lrcorner (\beta \wedge d\beta) = 0$ (see Section 1.1), we have $L_{X_0} \beta = f \cdot \beta$, for some function f . This implies that X_0 preserves \mathcal{E} . Therefore, we have $\xi(\mathcal{E})_{\pi(p)} := (d\pi)_p(\mathcal{E}_p) = (d\pi)_q(\mathcal{E}_q)$ for any point q on the same leaf of $L(\mathcal{E})$ as p because π is the projection along $L(\mathcal{E})$ or X_0 . It is known that this distribution $\xi = \xi(\mathcal{E})$ is a contact structure on $W/L(\mathcal{E})$ (see [M2], [Ge]). We call this $(W/L(\mathcal{E}), \xi(\mathcal{E}))$ the *deprolongation* of the Engel structure \mathcal{D} .

Let (W, \mathcal{D}) be an Engel manifold with the characteristic foliation $L(\mathcal{D}^2)$, and $M \subset (W, \mathcal{D})$ an embedded 3-manifold. We assume that M is transverse to the characteristic foliation L . Then we can take a neighborhood U of M as a flow-box for L . In this neighborhood U , the foliation L is nice in the sense above. Thus we can apply the deprolongation procedure. In this case, we can identify the leaf space $U/L(\mathcal{D}^2)$ with M . Then the obtained contact structure is $\pi_* \mathcal{D}^2 = TM \cap \mathcal{D}^2$. In the case where the Engel manifold is a prolongation $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ of a contact structure ξ on a 3-manifold M and embedded 3-manifold is a cross section M_θ , the characteristic foliation $L(\mathcal{D}(\xi)^2)$ is nice globally. Then, the leaf space $\mathbb{P}(\xi)/L(\mathcal{D}^2)$ is identified with $M_\theta = M$ and the obtained structure is the original ξ .

1.3 Twisting property and Development mappings.

The development mapping is a local Engel diffeomorphism or an immersion into a prolongation $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ or $(\tilde{\mathbb{P}}(\xi), \tilde{\mathcal{D}}(\xi))$, introduced in [M2]. It is constructed by a property that an Engel structure is twisting along leaves of its characteristic foliation. First, we observe the twisting condition of Engel structures. Let us recall that an Engel structure \mathcal{D} contains its characteristic line field $\mathcal{L} = \mathcal{L}(\mathcal{D}^2) \subset \mathcal{D}$ of $\mathcal{D}^2 =: \mathcal{E}$. Let $\tilde{\mathcal{D}}$ be another rank 2 distribution which is contained in \mathcal{E} and contains $\mathcal{L} = \mathcal{L}(\mathcal{E})$: $\mathcal{L} \subset \tilde{\mathcal{D}} \subset \mathcal{E}$. Then the *twisting condition*:

$$\tilde{\mathcal{D}} + [\mathcal{L}, \tilde{\mathcal{D}}] = \mathcal{E} \tag{1.2}$$

implies that $\tilde{\mathcal{D}}$ is Engel, that is, the Engel condition (1.1). Let X_0 be a characteristic vector field of \mathcal{E} , and V a vector field which forms a basis of $\tilde{\mathcal{D}}$ with X_0 . We note $[V, \mathcal{E}] \not\subset \mathcal{E}$ because V is independent of the integrable subdistribution $\mathcal{L}(\mathcal{E}) \subset \mathcal{E}$. Then the derived distributions are

$$\begin{aligned} \tilde{\mathcal{D}}^2 &= \tilde{\mathcal{D}} + [\mathcal{L}, \tilde{\mathcal{D}}] + [V, \tilde{\mathcal{D}}] = \mathcal{E}, \\ \tilde{\mathcal{D}}^3 &= \mathcal{E} + [\mathcal{L}, \mathcal{E}] + [V, \mathcal{E}] = \mathcal{E} + [V, \mathcal{E}], \end{aligned}$$

where we use the fact that the rank of $\tilde{\mathcal{D}}$ is 2. Therefore we obtain $\dim \tilde{\mathcal{D}}^2 = 3$, $\dim \tilde{\mathcal{D}}^2 = 4$, namely, the Engel condition (1.1).

Using this twisting condition, we construct a mapping from a domain in an Engel manifold with a nice characteristic foliation to a prolongation of some contact structure. Let (W, \mathcal{D}) be an Engel manifold, and $L = L(\mathcal{D}^2)$ the characteristic foliation. Let $U \subset (W, \mathcal{D})$ be a domain where the characteristic foliation L is nice in the sense above, and $\pi: U \rightarrow U/L$ the projection to the leaf space. We set $\xi := \pi_*(\mathcal{D}^2)$. It is a deprolonged contact structure on U/L from \mathcal{D} . Let $l \subset W$ be a leaf of L , and $q \in l \cap U$ a point. From another point of view, l is a point of the leaf space U/L . For a point $q \in l$, there corresponds a tangent 2-plane $\mathcal{D}_q \subset T_q U$. Since an Engel distribution \mathcal{D} contains the characteristic line field $\mathcal{L} = \mathcal{L}(\mathcal{D}^2)$, and is contained in \mathcal{D}^2 : $\mathcal{L} \subset \mathcal{D} \subset \mathcal{D}^2$, there corresponds a tangent line $d\pi_q(\mathcal{D}_q) \subset d\pi_q(\mathcal{D}_q^2) = \xi_l$, that is, a point of $\mathbb{P}(\xi_l)$. In this way, we obtain a mapping from l to $\mathbb{P}(\xi_l)$. As the domain U with a nice foliation is regarded as a union of leaves $\cup_{l \cap U \neq \emptyset} (l \cap U)$, we obtain a map from a nice domain U to a prolongation $\mathbb{P}(\xi)$. We call this mapping $\Phi_{\mathcal{D}}: U \rightarrow \mathbb{P}(\xi)$ the *development mapping* associate to the Engel structure \mathcal{D} . The twisting condition (1.2), and the argument following it, ensure that this development mapping is diffeomorphic locally. From the construction, the development mapping $\Phi_{\mathcal{D}}$ preserves the characteristic line field and another line field in the Engel distribution twisting in the sense of the twisting condition, with respect to the given \mathcal{D} on U and the prolongation $\mathcal{D}(\xi)$ on $\mathbb{P}(\xi)$. Therefore the development mapping is an Engel diffeomorphic locally (see [M2]). We consider the lift $\tilde{\Phi}_{\mathcal{D}}: U \rightarrow \tilde{\mathbb{P}}(\xi)$ of the development mapping. We also call this the development mapping.

Now, we define the twisting number for Engel structures on $M \times S^1$ and $M \times I$, with trivial characteristic foliations. We begin with $M \times S^1$. Let \mathcal{D} be an Engel structure on $M \times S^1$ with a trivial characteristic foliation, and $\xi = \xi(\mathcal{D})$ its deprolongation. Let $l \in L(\mathcal{D}^2)$ be a leaf of the characteristic foliation corresponding to a point $p \in M = (M \times I)/L(\mathcal{D}^2)$. We note that l is diffeomorphic to S^1 . Then we obtain a mapping from $l \cong S^1$ to $\mathbb{P}(\xi_p) \cong \mathbb{R}P^1 \cong S^1$, defined as $\theta \mapsto \mathcal{D}_{(p,\theta)} \cap T_p M$, which can be regarded as a mapping $S^1 \rightarrow S^1$. The *twisting number* $\text{tw}(\mathcal{D})$ of \mathcal{D} is defined as the degree of this mapping. We suppose that the orientation of a fibre l is defined by the characteristic vector field X_0 . Considering the basis (v_0, v_1) of ξ such that $[X_0, v_0] = v_1$, we obtain an orientation of ξ , and then that of $S^1 \cong \mathbb{P}(\xi_p)$. We consider the above degree with respect to those orientations. We note that it is independent of the choice of points $p \in M$. In other words, the Engel structure \mathcal{D} with the twisting number $\text{tw}(\mathcal{D}) = n$ is Engel diffeomorphic to $(\mathbb{P}_n(\xi), \mathcal{D}_n(\xi))$ by the

development mapping, where $\xi = \xi(\mathcal{D})$. Next, we define the minimal twisting number for Engel structures on $M \times I$ with trivial characteristic foliations. Let $\bar{\mathcal{D}}$ be an Engel structure on $M \times I$ with the trivial characteristic foliation, and $\bar{\xi} = \xi(\bar{\mathcal{D}})$ its deprolongation. We take a pair (V_0, V_1) of non-vanishing vector fields on M , which is a positively oriented basis of ξ as above, such that V_0 defines the induced Legendrian foliation $\mathcal{F}_0 = \mathcal{F}(M \times \{0\}, \bar{\mathcal{D}})$. Then we obtain a family $g_t: M \rightarrow \mathbb{R}$ of functions, which satisfies that $g_0 \equiv 0$ and that the vector fields $(V_0 \cdot \cos(g_t\pi) + V_1 \cdot \sin(g_t\pi))$ define the line fields $\bar{\mathcal{D}} \cap TM_t$, by identifying M_t with M . We call the non-negative integer $n \in \mathbb{Z}_{\geq 0}$ such that $n \leq \min_{p \in M} g_1 < n + 1$ the *minimal twisting number* of $\bar{\mathcal{D}}$. Let $\text{tw}(\bar{\mathcal{D}})$ denote it. We note that it is independent of the choice of V_1 and the orientation of V_0 .

2 Characterization on $M \times S^1$

In this section, we prove Theorem 1. First, we show (1) of the theorem.

Proof of Theorem 1-(1) Let $\varphi_t: M \times S^1 \rightarrow M \times S^1$, $t \in [0, 1]$, be a given isotopy between $\bar{\mathcal{D}}(\xi)$ and $\bar{\mathcal{D}}(\zeta)$, which satisfies $\varphi_0 = \text{id}$, $\varphi_{1*}(\bar{\mathcal{D}}(\zeta)) = \bar{\mathcal{D}}(\xi)$, and $(\varphi_t)_*L = L$, where $L = L(\bar{\mathcal{D}}(\xi)) = L(\bar{\mathcal{D}}(\zeta))$ is a trivial characteristic foliation. We set $\mathcal{D}_t := (\varphi_t)_*\bar{\mathcal{D}}(\zeta)$. It is a family of Engel structures with the same characteristic foliation L . Let \mathcal{E}_t denote an even-contact structure \mathcal{D}_t^2 on $M \times S^1$. We set $M(t) := \varphi_t(M_0) \subset M \times S^1$, where $M_0 = M \times \{0\} \subset M \times S^1$ is the zero section. We note that $M(t)$ intersects every leaf of L transversely, for any $t \in [0, 1]$. As mentioned in Section 1.2, $\xi_t := TM(t) \cap \mathcal{E}_t$ is a contact structure on $M(t)$. Each $M(t)$ is sent to M_0 by a time one mapping of a vector field $f_t \cdot (\partial/\partial\theta) =: W_t$ for some function f_t , where $\theta \in S^1$ is the coordinate of a fibre. Let $\psi_1^t: M \times S^1 \rightarrow M \times S^1$ be this family of time one mappings. Each mapping ψ_1^t preserves each even-contact structure \mathcal{E}_t , because $\partial/\partial\theta$ is the characteristic vector field for each \mathcal{E}_t (See Section 1.2). Then, the restriction of $\psi_1^t \circ \varphi_t: M \times S^1 \rightarrow M \times S^1$ to $M_0 = M$ is the required isotopy. In fact, we have $\psi_1^t \circ \varphi_t(M_0) = M_0$, $\psi_1^0 \circ \varphi_0 = \text{id}$, and

$$\begin{aligned} (\psi_1^1 \circ \varphi_1)_*\zeta &= \psi_{1*}^1 \circ \varphi_{1*}(TM_0 \cap \bar{\mathcal{D}}(\zeta)^2) \\ &= \psi_{1*}^1(TM(1) \cap \bar{\mathcal{D}}(\xi)^2) \\ &= TM_0 \cap \bar{\mathcal{D}}(\xi)^2 = \xi. \end{aligned} \quad \square$$

Next, we show (2) of Theorem 1.

Proof of Theorem 1-(2) Let \mathcal{D} be a given Engel structure on $M \times S^1$ with the trivial characteristic foliation L . We set $\mathcal{E} := \mathcal{D}^2$. It is an even-contact structure on $M \times S^1$. We identify the leaf space $(M \times S^1)/L$ with $M_0 = M \times \{0\} \subset M \times S^1$. Then the projection $M \times S^1 \rightarrow (M \times S^1)/L$ is the first projection $\pi: M \times S^1 \rightarrow M = M_0$. In terms of Section 1.2, this foliation L is nice. According to a deprolongation procedure, we obtain a contact structure $\xi := \pi_*\mathcal{E}$ on M (see Section 1.2). Let $n \in \mathbb{N}$ be the twisting number of \mathcal{D} : $\text{tw}(\mathcal{D}) = n$. We show that the given structure \mathcal{D} is isotopic, preserving the characteristic foliation L , to an n -fold prolongation $\bar{\mathcal{D}}_n(\xi)$ of a deprolongation ξ . Now, we consider a development mapping $\Phi_{\mathcal{D}}: (M \times S^1, \mathcal{D}) \rightarrow (\mathbb{P}(\xi), \mathcal{D}(\xi))$, defined in Section 1.3. In this case, the characteristic foliation is nice globally, and each leaf is S^1 . Therefore, it is immersed into a prolongation $(\mathbb{P}(\xi), \mathcal{D}(\xi))$ covering n times. In fact, each leaf $l \in L$ is immersed onto each leaf of the characteristic foliation of $\mathcal{D}(\xi)^2$, winding n times, because a line $d\pi(\mathcal{D}) \subset \xi$ twists $n/2$ times along l . Then we obtain an Engel diffeomorphism $\tilde{\Phi}(\mathcal{D}): (M \times S^1, \mathcal{D}) \rightarrow (\mathbb{P}_n(\xi), \mathcal{D}_n(\xi))$ as a lift for a fibrewise covering mapping $\varphi_n: (\mathbb{P}_n(\xi), \mathcal{D}_n(\xi)) \rightarrow (\mathbb{P}(\xi), \mathcal{D}(\xi))$. By a canonical identification ψ_n , we obtain an Engel diffeomorphism $\psi_n^{-1} \circ \tilde{\Phi}(\mathcal{D}): (M \times S^1, \mathcal{D}) \rightarrow (M \times S^1, \bar{\mathcal{D}}_n(\xi))$. We note that it is isotopic to identity because it is a bundle map over identity between product bundles. \square

This Theorem 1 implies that Engel structures on $M \times S^1$ with the trivial characteristic foliation are classified, up to isotopy, if contact structures on the 3-manifold M are classified. The classification of contact structure has been an important problem for a long time. There are some results on this subject (for example, [El1], [El2], [K], [Et], [Gi], [H]). Here we take S^3 for example.

Example Let us consider Engel structures on $S^3 \times S^1$ with trivial characteristic foliations. Contact structures on S^3 are classified, up to isotopy, to the following structures (see [El1], [El2]): a tight structure ζ , overtwisted structures ξ_m , $m \in \mathbb{Z}$. Then, any Engel structure on $S^3 \times S^1$ with a trivial characteristic foliation is isotopic to one of the followings:

$$\bar{\mathcal{D}}_n(\zeta), \quad \bar{\mathcal{D}}_n(\xi_m), \quad n \in \mathbb{N}, \quad m \in \mathbb{Z}.$$

These Engel structures are not isotopic each other.

3 Characterization on $M \times I$

In this section, we prove Theorem 2. First, we show that the given pair of Legendrian foliations on the contact manifold (M, ξ) can be extended to an

Engel structure on $M \times I$ with a trivial characteristic foliation so that it has the given non-negative integer as the minimal twisting number. This implies Theorem 2-(2). It is also proved that such Engel structures are determined by the given contact structures, pairs of Legendrian foliations, and non-negative integers. Next, we construct a homotopy between the given Engel structures which preserves the trivial characteristic foliation. Then, we apply Theorem 1.2 to show Theorem 2-(1).

3.1 Extension of Engel structures from $M \times \partial I$ to $M \times I$.

We show the following Proposition. This implies the second part of Theorem 2.

Proposition 3.1 *Let M be a compact orientable 3-manifold. We suppose that a parallelizable contact structure ξ on M , a pair $(\mathcal{F}_0, \mathcal{F}_1)$ of Legendrian foliations on (M, ξ) , and a non-negative integer $n \in \mathbb{Z}_{\geq 0}$ are given. Then an Engel structure $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n) = \mathcal{D}$ with a trivial characteristic foliation, the induced contact structure $\xi(\mathcal{D}) = \xi$, the induced Legendrian foliations $\mathcal{F}(M \times \{i\}, \mathcal{D}) = \mathcal{F}_i$, $i = 0, 1$, and the minimal twisting number $\text{tw}_-(\mathcal{D}) = n$, is determined up to isotopy by the given ξ , \mathcal{F}_0 , \mathcal{F}_1 , and n .*

Proof Since the given contact structure ξ is parallelizable, there exists a global framing of ξ . Let (V_0, V_1) be a pair of non-vanishing vector fields on M which spans ξ . We can take this pair so that V_0 defines the given Legendrian foliation \mathcal{F}_0 . Then, the Legendrian directions are described by this framing (V_0, V_1) . Therefore, we obtain a function $g: M \rightarrow \mathbb{R}$ such that the vector field $(V_0 \cdot \cos g + V_1 \cdot \sin g)$ generates the given Legendrian foliation \mathcal{F}_1 , and that it has its minimum value between 0 and π : $0 < \min_{p \in M} g(p) \leq \pi$. We define the distribution $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ of rank 2 on $M \times I$ as the plane field spanned by the vector fields $\partial/\partial t$ and V^n , where $t \in I$ is a parameter and

$$V^n := V_0 \cdot \cos(t(g + n\pi)) + V_1 \cdot \sin(t(g + n\pi)), \quad n \in \mathbb{Z}_{\geq 0}.$$

We note that this distribution $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ is Engel. It is proved by an easy calculation as follows. The Lie bracket

$$\left[\frac{\partial}{\partial t}, V^n \right] = (g + n\pi) \cdot \{-V_0 \cdot \sin(t(g + n\pi)) + V_1 \cdot \cos(t(g + n\pi))\} =: U^n$$

is independent of the distribution $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$. In addition, the Lie bracket

$$[V^n, U^n] = (g + n\pi) \cdot [V_0, V_1]$$

is independent of $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ and U^n because (V_0, V_1) is a framing of a contact structure, that is, a completely non-integrable distribution. Then $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ is Engel. The characteristic foliation of this structure is trivial: $L(\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)^2) = \text{Span}\langle \partial/\partial t \rangle$. It is nice globally on $M \times I$. From the construction, it is clear that the induced contact structure by the deprolongation procedure is the given ξ . In addition, the induced Legendrian foliations on $M \times \{i\}$, $(i = 0, 1)$, is $\mathcal{F}(M \times \{i\}, \mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)) = \mathcal{F}_i$, and the minimal twisting number is $\text{tw}_-(\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)) = n$. We observe that this structure $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ depends only on the given $\xi, \mathcal{F}_0, \mathcal{F}_1$, and n , up to an isotopy. We show that it is independent of the choices of the framing (V_0, V_1) of the given contact structure. Let $(\tilde{V}_0, \tilde{V}_1)$ be another choice of the framing of ξ , such that \tilde{V}_0 defines the Legendrian foliation \mathcal{F}_0 , and that it has the same orientation as the frame (V_0, V_1) . Then, there exists a matrix valued function, with a positive determinant,

$$A(p) = \begin{pmatrix} f_1(p) & 0 \\ f_2(p) & f_3(p) \end{pmatrix},$$

which represents a transformation between $(\tilde{V}_0, \tilde{V}_1)$ and (V_0, V_1) :

$$\begin{pmatrix} V_0 \\ V_1 \end{pmatrix} = \begin{pmatrix} f_1(p) & 0 \\ f_2(p) & f_3(p) \end{pmatrix} \begin{pmatrix} \tilde{V}_0 \\ \tilde{V}_1 \end{pmatrix}.$$

We note that f_1, f_3 are non-vanishing functions with the same sign. Then we have a family of matrix valued functions $A_s(p)$, $s \in [0, 1]$, between $A_0(p) = A(p)$ and $A_1 = \pm \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, with positive determinants: $|A_s(p)| > 0$. We set

$$\begin{pmatrix} V_0^s \\ V_1^s \end{pmatrix} := A_s \begin{pmatrix} \tilde{V}_0 \\ \tilde{V}_1 \end{pmatrix}.$$

It is a family of bases of the given contact structure ξ , between $(V_0^0, V_1^0) = (V_0, V_1)$ and $(V_0^1, V_1^1) = \pm(\tilde{V}_0, \tilde{V}_1)$. We construct a family \mathcal{D}^s , $s \in [0, 1]$, of Engel structures on $M \times I$ as above with respect to the bases (V_0^s, V_1^s) . We note that we obtain the same Engel structure \mathcal{D}^1 for both $\pm(\tilde{V}_0, \tilde{V}_1)$. These contact structures coincide at the ends $M \times \partial I$. In fact, the defining vector fields $(V^n)_s = V_0^s \cdot \cos(t(g_s + n\pi)) + V_1^s \cdot \sin(t(g_s + n\pi))$ are taken so that they determine \mathcal{F}_i on $M \times \{i\}$, $i = 0, 1$, for all $s \in [0, 1]$. From the construction, their characteristic foliations are constant: $L((\mathcal{D}^s)^2) = \text{Span}\langle \partial/\partial t \rangle$. According to the relative version of Theorem 1.2, this family \mathcal{D}^s is described by a global isotopy. This implies that the induced Engel structure $\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ is independent of the choice of the framing of the given contact structure ξ . \square

By using the development mappings, the Engel manifold $(M \times I, \mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n))$ above is regarded as a certain subset of the prolongation of ξ . We consider the development mapping $\Phi_{\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)}: (M \times I, \mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)) \rightarrow (\tilde{\mathbb{P}}(\xi), \tilde{\mathcal{D}}(\xi))$. It is an Engel embedding. In this case, the development mapping $\Phi_{\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)}$ is described in terms of V^n as follows:

$$\Phi_{\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)}: (p, t) \mapsto (p, [(V^n)_{(p,t)}]),$$

where $[(V^n)_{(p,t)}]$ is a point of $\tilde{\mathbb{P}}(\xi_p)$ represented by the line in ξ_p defined by $(V^n)_{(p,t)}$. We set $Q(\xi, \mathcal{F}_0, \mathcal{F}_1, n) := \text{Im}\Phi_{\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)}$ and

$$M_n(\mathcal{F}_i) := \Phi_{\mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)}(M \times \{i\}), \quad i = 0, 1,$$

that is,

$$\begin{aligned} M_n(\mathcal{F}_0) &= \{(p, [(V_0)_p]) \mid p \in M\}, \\ M_n(\mathcal{F}_1) &= \{(p, [V_0 \cdot \cos(g + n\pi) + V_1 \cdot \sin(g + n\pi)]) \mid p \in M\}. \end{aligned}$$

As the given contact structure ξ on M is parallelizable, $\tilde{\mathbb{P}}(\xi)$ is identified with $M \times \mathbb{R}$ by the relation

$$\Psi_{(V_0, V_1)}: \tilde{\mathbb{P}}(\xi) \rightarrow M \times \mathbb{R}, \quad (p, [(V_0 \cdot \cos s + V_1 \cdot \sin s)_p]) \mapsto (p, s),$$

with respect to the framing (V_0, V_1) . By this identification, $M_n(\mathcal{F}_0)$ corresponds to the zero-section $M \times \{0\} \subset M \times \mathbb{R}$, and $M_n(\mathcal{F}_1)$ corresponds to the graph $\{(p, g(p) + n\pi) \in M \times \mathbb{R} \mid p \in M\}$ of the function $g + n\pi$ on M .

At the end of this section, we observe a version of the above proposition for families of Legendrian foliations and minimal twisting numbers. We suppose that a parallelizable contact structure ξ on M , a family $(\mathcal{F}_0^s, \mathcal{F}_1^s)$, $s \in [0, 1]$, of Legendrian foliations on (M, ξ) , and non-negative integers $n(s) \in \mathbb{Z}_{\geq 0}$ depending on $s \in [0, 1]$ are given. We suppose that $n(s)$ changes one by one. Let (V_0^s, V_1^s) be a family of framings of ξ , such that V_0^s generate \mathcal{F}_0^s , $s \in [0, 1]$. Then there exists a family $g_s: M \rightarrow \mathbb{R}$ of functions, such that $(V_0^s \cdot \cos g_s + V_1^s \cdot \sin g_s)$ generate \mathcal{F}_1^s and $n(s)\pi \leq \min_{p \in M} g_s < (n(s) + 1)\pi$. In a similar way to the proof of Proposition 3.1, we construct a family $\mathcal{D}(\xi, \mathcal{F}_0^s, \mathcal{F}_1^s, n(s))$ of Engel structures on $M \times I$ as plane fields spanned by $\partial/\partial t$ and $(V_0^s \cdot \cos g_s + V_1^s \cdot \sin g_s)$. By similar arguments to the proof of Proposition 3.1, $\mathcal{D}^s := \mathcal{D}(\xi, \mathcal{F}_0^s, \mathcal{F}_1^s, n(s))$ is a family of Engel structures on $M \times I$ with trivial characteristic foliations, the induced contact structure $\xi(\mathcal{D}^s) = \xi$, the induced Legendrian foliations $\mathcal{F}(M \times \{i\}, \mathcal{D}^s) = \mathcal{F}_i^s$, ($i = 0, 1$), and the minimal twisting numbers $\text{tw}(\mathcal{D}^s) = n(s)$. The obtained family \mathcal{D}^s of Engel structures is determined up to isotopy by the given ξ , \mathcal{F}_0^s , \mathcal{F}_1^s , and $n(s)$, as above.

3.2 Proof of Theorem 2.

In this Section, we prove Theorem 2-(1). We take $J := [-1, 1]$ as a closed interval instead of $I = [0, 1]$, for convenience. Let \mathcal{D} be an Engel structure on $M \times J$ with the trivial characteristic foliation. This Engel structure has the induced contact structure $\xi = \xi(\mathcal{D})$, the induced Legendrian foliations $\mathcal{F}_i := \mathcal{F}(M \times \{i\}, \mathcal{D})$, $i = \pm 1$, and the minimal twisting number $n = \text{tw}_-(\mathcal{D})$. We show that the given Engel structure \mathcal{D} is isotopic to the Engel structure $\mathcal{D}(\xi, \mathcal{F}_{-1}, \mathcal{F}_1, n)$ from Proposition 3.1. This implies that any Engel structure on $M \times J$ which has the same induced contact structure ξ on M , pair of Legendrian foliations $(\mathcal{F}_{-1}, \mathcal{F}_1)$ on $M \times \partial J$, and minimal twisting number n , is isotopic to $\mathcal{D}(\xi, \mathcal{F}_{-1}, \mathcal{F}_1, n)$, that is, Theorem 2-(1). We set $W_s := M \times [-s, s] \subset M \times J$ for $s \in [0, 1]$. We note that the induced contact structure on M for $\mathcal{D}|_{W_s}$ are $\xi = \xi(\mathcal{D})$ constantly for all $s \in [0, 1]$. We set $\mathcal{F}_t := \mathcal{F}(M \times \{t\}, \mathcal{D})$, $t \in [-1, 1]$. Identifying $M \times \{t\} \subset M \times J$ with M by the standard projection, \mathcal{F}_t can be regarded as a family of Legendrian foliations on (M, ξ) . Let $n(s) := \text{tw}_-(\mathcal{D}|_{W_s})$ be the minimal twisting number of \mathcal{D} restricted to W_s . We note that $n(1) = \text{tw}_-(\mathcal{D})$, $n(\varepsilon) = 0$ for sufficiently small $\varepsilon > 0$, and that it is monotone with respect to $s \in (0, 1]$. According to Proposition 3.1 and its version for families, we obtain a family $\tilde{\mathcal{D}}_s$, $s \in [0, 1]$, of Engel structures on $M \times I$ which have

$$\begin{aligned} \xi(\tilde{\mathcal{D}}_s) &= \xi, \quad \mathcal{F}(M \times \{0\}, \tilde{\mathcal{D}}_s) = \mathcal{F}_{-s}, \quad \mathcal{F}(M \times \{1\}, \tilde{\mathcal{D}}_s) = \mathcal{F}_s, \\ &\text{and} \quad \text{tw}_-(\tilde{\mathcal{D}}_s) = n(s). \end{aligned}$$

Applying a family of diffeomorphisms $\psi_s: M \times I \rightarrow W_s = M \times [-s, s]$, preserving fibres, we obtain a family \mathcal{D}_s of Engel structures on each W_s with the trivial characteristic foliation, which is endowed with the given informations:

$$\xi(\mathcal{D}_s) = \xi, \quad \mathcal{F}(M \times \{\pm s\}, \mathcal{D}_s) = \mathcal{F}_{\pm s}, \quad \text{and} \quad \text{tw}_-(\mathcal{D}_s) = n(s).$$

Now, we consider the following family \mathcal{E}_s , $s \in [\varepsilon, 1]$, of Engel structures on $M \times J$, where $\varepsilon > 0$ is sufficiently small,

$$\mathcal{E}_s := \begin{cases} \mathcal{D} & \text{on } (M \times J) \setminus W_s, \\ \mathcal{D}_s & \text{on } W_s. \end{cases}$$

We note that Theorem 1.1 guarantees the pasting of Engel structures along $M \times \{\pm s\}$. This family is a path, relative to the ends $M \times \partial J$, between \mathcal{E}_ε and $\mathcal{E}_1 = \mathcal{D}_1$. The structure $\mathcal{D}_1 = \mathcal{D}(\xi, \mathcal{F}_0, \mathcal{F}_1, n)$ is determined, up to isotopy, only by the given contact structure, pair of Legendrian foliations, and non-negative integer. According to Theorem 1.1, the germ of Engel structure along $M \times \{0\}$ is determined only by the induced Legendrian foliation $\mathcal{F}(M \times \{0\}, \mathcal{D})$

on $M \times \{0\}$. Therefore, the structure \mathcal{E}_ε is isotopic to the given structure \mathcal{D} . We note that the family \mathcal{E}_s above preserves the trivial characteristic foliation: $\mathcal{L}(\mathcal{E}_s^2) \equiv \text{Span}\langle \partial/\partial t \rangle$, so we can apply the relative version of Theorem 1.2. Consequently, the given Engel structure is isotopic, relative to the ends $M \times \partial I$, to the Engel structure

$$\mathcal{D}(\xi(\mathcal{D}), \mathcal{F}(M \times \{-1\}), \mathcal{F}(M \times \{1\}), \text{tw}_-(\mathcal{D})),$$

which depends only on the induced contact structure and Legendrian foliations on both ends, and the minimal twisting number. \square

Let us conclude this paper by an open problem. The results of this paper need some conditions. It is natural and might be interesting to consider more general cases.

Question Let ξ_0, ξ_1 be contact structures on a 3-manifold M , which are not isomorphic to each other. Is there any Engel structure \mathcal{D} on a 4-manifold $M \times I$, whose characteristic foliation $\mathcal{L}(\mathcal{D}^2)$ is transverse to both $M \times \{0\}$, $M \times \{1\}$, and which induce the given contact structures ξ_0, ξ_1 on $M \times \{0\}$, $M \times \{1\}$, respectively?

We note that there must be leaves of characteristic foliation which do not intersect both ends $M \times \{0\}$, $M \times \{1\}$, if such an Engel structure exists.
