

On symplectic fillings

JOHN B ETNYRE

Abstract In this note we make several observations concerning symplectic fillings. In particular we show that a (strongly or weakly) semi-fillable contact structure is fillable and any filling embeds as a symplectic domain in a closed symplectic manifold. We also relate properties of the open book decomposition of a contact manifold to its possible fillings. These results are also useful in showing the contact Heegaard Floer invariant of a fillable contact structure does not vanish [28] and property P for knots [18].

Keywords Tight, symplectic filling, convexity

1 Introduction

It is important to consider various notion of “symplectic filling” when studying contact and symplectic manifolds (especially in low dimensions). In particular, it is useful to understand when a contact structure on a three manifold has a symplectic filling, what type of filling is it and if there are restrictions on the topology of the filling.

Consider a contact three manifold (M, ξ) and symplectic manifold (X, ω) with M a boundary component of X and $\omega|_{\xi} > 0$. If all the boundary components of X are convex then (X, ω) is a weak (or possibly strong) semi-filling of (M, ξ) . (Throughout this paper all contact structures will be (co)oriented, contact manifolds will be oriented by their contact structures and symplectic manifolds will be oriented by their symplectic structures.) We say the boundary component M of X can be *symplectically capped off* if there is a symplectic manifold (X', ω') such that $X' \setminus M = X \cup C, \omega'|_X = \omega$ and C is compact. (Note this implies that $\partial C = -M$.) The symplectic manifold $(C, \omega'|_C)$ is called a symplectic cap for $(M, \xi) \subset (X, \omega)$. (The notation $A \setminus B$ means the union of the metric completions of the components of A minus B .) Many of our results rely on the following theorem.

Theorem 1.1 *If (X, ω) is a (weak or strong) symplectic filling (or semi-filling) of (M, ξ) then the boundary component M of X can be capped off symplectically.*

We have the following immediate corollaries.

Corollary 1.2 *A weakly, respectively strongly, semi-fillable contact structure is weakly, respectively strongly, fillable. \square*

Corollary 1.3 *Any symplectic four manifold with weakly or strongly convex boundary components can be embedded as a domain in a closed symplectic manifold. \square*

The theorem and both corollaries have also been established by Eliashberg in [3]. For *strong* (semi)fillings these results were essentially proven by Gay in [13] and follow from Theorem 1.3 in [11]. Moreover, after writing this paper the author learned that Stipsicz and Ghiggini also know how to prove these results for strong fillings. Moreover, in [29], Stipsicz has a different proof of Lemma 3.1 (below), which is the key ingredient in the proof of Theorem 1.1. In [23] Lisca and Matić and in [1] Akbulut and Ozbagci proved the corollaries for Stein fillings. Not only do these corollaries illuminate the nature of symplectic and contact geometry in low dimensions they have many important applications. Specifically, Kronheimer and Mrowka [18] can use Corollary 1.2 to prove the Property P conjecture for knots and Ozsváth and Szabó [28] can use Corollary 1.3 to show that their Heegaard Floer contact invariant does not vanish for fillable contact structures. Moreover, they can use the corollary to give an alternate proof that if p surgery on a knot K yields a manifold which is (orientation preserving) homeomorphic to $L(p, 1)$ then K is the unknot (this result first appeared in [20] using Seiberg–Witten Floer Homology).

We now turn to the topology of a symplectic filling. A fundamental result of Giroux [14] (see also [16]) says that a contact structure ξ on a three manifold M is always supported by an open book (L, ϕ) . That is, comes from the construction of Thurston and Winkelnkemper [30]; or more explicitly, there is a link L in M that is transverse to ξ such that $M \setminus L$ is fibered by Seifert surfaces for L and the contact structure can be isotoped to be arbitrarily close to the fibers in the fibration (while keeping L transverse). The *monodromy* of the open book ϕ is the monodromy of the fibration $M \setminus L$.

Theorem 1.4 *Suppose the contact structure ξ on a three manifold M is supported by the open book (L, ϕ) and there is a diffeomorphism ψ of the*

fiber such that $(L, \psi \circ \phi)$ is an open book for S^3 and ψ can be written as a composition of right handed Dehn twists. If (X, ω) is a, weak or strong, symplectic semi-filling of (M, ξ) then (X, ω) is a filling of (M, ξ) . Moreover, if M is a rational homology sphere then $H_1(X; \mathbb{Z})$ finite (and trivial if M is an integral homology sphere) and the intersection form on $H_2(X; \mathbb{Z})$ is negative definite.

Lisca (in [21, 22]) and Ohta–Ono (in [27]) have obtained a similar result under the assumption that M admits a metric of positive scalar curvature (but no assumption on the supporting open book). We note that if ϕ^{-1} can be written as a product of right handed Dehn twists then the conditions of the theorem are satisfied (see the proof of Lemma 3.1). If ϕ^{-1} can be so written then ϕ can be written as product of left handed Dehn twists. One might expect that this implies the associated contact structure is overtwisted, but this is not necessarily true, only if the open book “destabilizes.” In general it is quite subtle to decide if an open book destabilizes. It is also difficult to make general statements about representing a diffeomorphism in terms of Dehn twists.

Theorem 1.5 *Under the hypothesis of Theorem 1.4 any symplectic filling of (M, ξ) can be embedded as a symplectic domain in a rational surface.*

While these theorems seem to provide potentially quite useful insights into the monodromy of open books we content ourselves here with the following simple applications.

Corollary 1.6 *Let ϕ be any monodromy associated to any tight contact structure coming from perturbing a Reebless foliation into a contact structure as in [9]. Then ϕ cannot be expressed as a composition of left handed Dehn twists. Moreover, there is no diffeomorphism ψ such that $\phi \circ \psi$ is the monodromy for an open book of S^3 and ψ is a composition of right handed Dehn twists.*

As a specific example any monodromy map associated to any tight contact structure on T^3 cannot be expressed as the composition of left handed Dehn twists.

Proof As shown in [9], such a contact structure on M is semi-filled by a symplectic form on $M \times [0, 1]$. This contradicts the conclusion of Theorem 1.4 and thus the contact structure cannot satisfy the hypothesis of Theorem 1.4. \square

Acknowledgments I thank Yasha Eliashberg for sharing an early version of [3] with me which made me aware of the many interesting applications of symplectic caps. I also thank the referee who provided invaluable suggestions for improvements on the paper. In addition, I gratefully acknowledge support from an NSF Career Grant (DMS-0239600) and FRG-0244663.

2 Symplectic fillings

We recall the various notions of symplectic fillings of contact manifolds. (For more details, see the survey paper [10], and for further discussion of the notions of fillability see [3].)

A symplectic manifold (X, ω) is said to have *strongly convex boundary* if there is a vector field v defined in the neighborhood of ∂X that points transversely out of X and dilates ω (ie, $\mathcal{L}_v \omega = \omega$). The form $\alpha = (\iota_v \omega)|_{\partial X}$ is a contact form on ∂X . The contact manifold $(M = \partial X, \xi)$ on the boundary is said to be *strongly symplectically fillable* by (X, ω) . If (X, ω) supports a Stein structure then (M, ξ) is said to be *holomorphically fillable* (this is sometimes called Stein fillable). A symplectic manifold (X, ω) is said to have *weakly convex boundary* if ∂X admits a contact structure ξ such that $\omega|_{\xi} > 0$. A contact manifold (M, ξ) is *weakly symplectically fillable* if it is the weakly convex boundary of a symplectic manifold. A contact structure is said to be weakly (or strongly) *semi-fillable* if it is one component of the boundary of a weakly (or strongly) convex symplectic manifold. (Note a Stein manifold always has a connected boundary so there is no notion of holomorphically semi-fillable.) When talking about strong or weak symplectic fillings we will frequently drop the word “symplectic” and just refer to strong or weak fillings.

The following diagram indicates the hierarchy of contact structures.

The properness of the inclusion of the set of weakly symplectically semi-fillable contact structures into the set of tight contact structures was shown in [12]

(for further examples see [24]). The properness of the inclusion of the set of strongly fillable structures into the set of weakly fillable structures is due to Eliashberg [4] (for further examples see [2]). The equalities of the semi-fillings and “honest” fillings is the content of Corollary 1.2 and [3]. Though there are strong fillings of a contact structure that are not holomorphic fillings (because there is more than one boundary component [25]) it is not currently known if strongly fillable contact structures are also holomorphically fillable.

If M is a rational homology sphere, a weak symplectic filling can be modified into a strong symplectic filling [27] (the germ of the argument originally appeared in [6], see also [3]). If M has a positive scalar curvature metric, then moreover a semi-filling is automatically a one boundary component filling, and all four notions of symplectic filling become the same (this is due to Lisca [21] and Ohta–Ono [27]). The proof builds on the work of Kronheimer and Mrowka [19] and relies on Seiberg–Witten theory.

3 Proof of Theorem 1.1

For the proof of Theorem 1.1 we will need the following lemma (see also [29]).

Lemma 3.1 *Under the hypothesis of Theorem 1.1, 2–handles may be attached to X to form a new symplectic manifold with weakly convex boundary (X', ω') such that $X' \setminus M = X \cup B$ with $\partial B = M' \cup (-M)$ where M' is a homology sphere.*

With this lemma in hand we prove Theorem 1.1

Proof of Theorem 1.1 Given (M, ξ) and (X, ω) as in the theorem, apply the above lemma to obtain (X', ω') . Since M' is a homology sphere the results of Ohta–Ono mentioned in the previous section imply ω' may be isotoped near M' so that (X', ω') is strongly convex along M' . Theorem 1.3 from [11] says that any contact manifold has (infinitely many) strongly concave fillings. Since a strongly convex and strongly concave filling may be glued to form a symplectic manifold [10] we see that (X', ω') may be symplectically capped off. Let C be the cap. Then $C \cup B$ (B from Lemma 3.1) is the symplectic cap for (M, ξ) . \square

We are left to prove the lemma.

Proof of Lemma 3.1 Giroux’s result about open books and contact structures implies we can assume that (M, ξ) is supported by an open book with connected binding (this can be achieved by “positive Hopf stabilization”). Let ϕ be the monodromy of the open book. Since the mapping class group is generated by right handed Dehn twists about arbitrary loops plus arbitrary Dehn twists parallel to the boundary, we can write ϕ^{-1} as $\phi_0 \circ \phi_1$, where ϕ_0 is a composition of right handed Dehn twists and ϕ_1 is some number of left handed Dehn twists parallel to the boundary (we can put all the boundary parallel twists at the end since they commute with the other Dehn twists). Thus by attaching 2–handles to X along M in a symplectic way (see [7, 15, 31]) we can get a symplectic manifold with a boundary component (M'', ξ'') , such that (M'', ξ'') is supported by an open book with monodromy $\phi \circ \phi_0$ which is, say, k right handed Dehn twists parallel to the boundary. Topologically the manifold is shown in the Figure 1. Now for each 1–handle in the figure add a 2–handle

Figure 1: On the left hand side we show an open book with k right handed Dehn twists parallel to the boundary. The right hand side is homeomorphic to the left hand side.

that runs over it once (this can be done in a symplectic way). We now have a symplectic manifold with boundary (M', ξ') . Topologically M' is obtained by $-\frac{1}{k}$ surgery on a knot in the three sphere, thus it is a homology sphere. \square

4 Topology of symplectic fillings

Proof of Theorem 1.4 and 1.5 Given the hypothesized diffeomorphism ψ we can repeat the proof of Lemma 3.1 and attach 2–handles to X along M to form a new symplectic manifold (X', ω') with new boundary component

(S^3, ξ') . Since ξ' is fillable we know it is tight. Thus ξ' is the unique tight contact structure on S^3 (see [5]). McDuff's well known extension [26] of Gromov's theorem [17] says that (X', ω') is symplectomorphic to the blow up of the standard symplectic structure on $B^4 \subset \mathbb{C}^2$. This of course implies our original symplectic filling (X, ω) only had one boundary component and that we may cap off (X', ω') by a symplectic disk bundle over S^2 to obtain a rational surface. This completes the proof of Theorem 1.5. To finish the proof of Theorem 1.4 simply note that if a rational homology sphere splits a rational surface as ours does then the component (X', ω') must be negative definite and $H_1(X; \mathbb{Z})$ must be torsional (and trivial if M is an integral homology sphere). \square
