

Partition complexes, duality and integral tree representations

ALAN ROBINSON

Abstract We show that the poset of non-trivial partitions of $\{1, 2, \dots, n\}$ has a fundamental homology class with coefficients in a Lie superalgebra. Homological duality then rapidly yields a range of known results concerning the integral representations of the symmetric groups Σ_n and Σ_{n+1} on the homology and cohomology of this partially-ordered set.

Keywords Partition complex, Lie superalgebra

1 Introduction

This paper reveals the geometry underlying certain integral representations of the symmetric groups. It claims few original results, but gives a unified geometrical and homological treatment and frequently strengthens the known theorems. Above all it aims to show that topological methods give efficient proofs of many of them.

Geometric realization converts the lattice of non-trivial partitions of a set with n elements into the space of fully-grown (that is, non-degenerate) trees with leaves labelled by the set $\{0, 1, \dots, n\}$. This space has reduced homology in degree $n - 3$ only. Its integral cohomology is a representation of Σ_n which is isomorphic to the Lie representation Lie_n , up to a twist by the sign character. It follows from the Σ_{n+1} -symmetry of the tree space that Lie_n extends to an integral representation of Σ_{n+1} .

Many mathematicians have contributed to the identification of the cohomology of the partition lattice with the twisted Lie representation: excellent summaries of the history of the theory are given in [6] and [12]. We show that the isomorphism arises at the cocycle level from a duality structure: the partition lattice has a fundamental homology cycle with coefficients in a certain Σ_n -module \mathfrak{S}_n ,

and the isomorphism is induced by cap product. The module \mathfrak{S}_n is the multilinear part of a free Lie superalgebra on n generators of odd degree: it is isomorphic to the twisted Lie representation, though not uniquely so.

In the final section we give a geometrical derivation of a short exact sequence relating these representations, due to S. Whitehouse [13].

The tree spaces are related to configuration spaces, and the occurrence of the Lie representations in this topological situation was observed by F. R. Cohen [3],[4].

2 The space of fully-grown n -trees

From [8] we recall topological properties of the space of n -trees, and prove a homeomorphism with the nerve of the lattice of partitions of the set $\{1, 2, \dots, n\}$.

A *tree* is a contractible 1-dimensional polyhedron X , and we shall always require X to be compact. There is a unique coarsest triangulation of X , in which no vertex lies on exactly two edges. A vertex meeting more than two edges is called a *node*; a vertex incident upon only one edge is a *free vertex*.

An edge which connects two nodes is an *internal* edge. An edge with a free vertex is called a *leaf*.

Following [1],[2], we introduce a moduli space of trees with a fixed number of leaves.

Definition 2.1 An n -tree is a tree with the following extra structure.

- (1) Every internal edge e is assigned a length l_e where $0 < l_e \leq 1$. All leaves are conventionally assigned a length of 1.
- (2) The free vertices are labelled by a bijective correspondence with the set $\{0, 1, \dots, n\}$.

If $n \geq 2$, then the labelling of free vertices is equivalent to a labelling of the leaves by a bijection with the same set $\{0, 1, \dots, n\}$. The leaf labelled 0 is also called the *root*. Two n -trees are regarded as equivalent if there is an isometry between them which preserves the labelling. A tree is *fully grown* if at least one internal edge has length 1.

Example 2.2 : the vertices v_A of T_n

Let A be any subset of the set $[n] = \{0, 1, \dots, n\}$ of labels, such that A and its complement $[n] \setminus A$ each have more than one element.

We define v_A to be the fully grown n -tree which has just one internal edge e_A (which necessarily has length 1), and which has the leaves labelled by elements of A attached at one end of this, and the leaves labelled by the elements of $[n] \setminus A$ at the other:

Since trees are regarded as the same when they are related by a label-preserving homeomorphism, it follows that $v_A = v_{[n] \setminus A}$.

In the next proposition Σ_{n+1} denotes the set of all permutations of $\{0, 1, \dots, n\}$, and Σ_n the subgroup leaving 0 fixed.

Proposition 2.3

- (1) The space T_n of all fully-grown n -trees is a simplicial complex of dimension $n - 3$, in which the vertices are the trees v_A of 2.2.
- (2) The space \tilde{T}_n of all n -trees is the cone on T_n .
- (3) The symmetric group Σ_{n+1} acts on the right upon the pair (\tilde{T}_n, T_n) by acting on the left upon the set of leaf labels. This action is simplicial.

Proof The proof is given in [8]. Suffice it to say here that \tilde{T}_n has an evident cubical structure, with the internal edge-lengths as cubical coordinates. On the subspace T_n the greatest edge-length is 1, so there is a simplicial structure with barycentric coordinates proportional to the edge-lengths: the vertices are the v_A of 2.2, and each k -simplex is an amalgam of $k + 1$ of the original cubes as illustrated for $k = 2$ on the left in the following diagram.

The space \tilde{T}_n is evidently a cone with T_n as its base. Its apex is a star-tree as illustrated on the right above, and the cone parameter maps a tree to its maximal internal edge-length. Therefore \tilde{T}_n can be triangulated as the cone on the simplicial complex T_n . As with T_n , the original cubical structure is a subdivision of this triangulation. □

From now on, we use the triangulations just constructed, unless the contrary is mentioned.

Lemma 2.4 *Every $(n - 4)$ -simplex of T_n is a face of exactly three top-dimensional simplices.*

Proof The top-dimensional simplices correspond to *binary trees* in which each node is the meet of three edges. An $(n - 4)$ -simplex of T_n arises from a tree with one exceptional node of order four: it faces three top-dimensional simplices corresponding to the three ways of resolving this node into two nodes of order three [8]. □

Lemma 2.4 shows that T_n has three-to-one incidence on codimension-one simplices. As is well known, a triangulated closed manifold has two-to-one incidence, and consequently has a fundamental top-dimensional homology class (with integer coefficients, possibly twisted). We shall see in §4 that T_n too has a fundamental homology class for which the coefficients are a certain module \mathfrak{S}_n .

Theorem 2.5 *The space T_n of fully-grown n -trees has the homotopy type of a wedge of $(n - 1)!$ spheres of dimension $n - 3$. The Σ_n -module $H_{n-3}(T_n)$ restricts to the regular integral representation of the subgroup Σ_{n-1} .*

Proof It is shown in [8] that T_n is obtained from a contractible space by attaching $(n - 1)!$ simplices of dimension $n - 3$ along their boundaries. These simplices correspond to the trees

where σ is any element of the permutation group Σ_{n-1} . Thus T_n has the homotopy type of a wedge of spheres, as claimed; and the homology classes of these spheres are regularly permuted by the subgroup Σ_{n-1} . □

2.6 Homeomorphism with the nerve of the partition lattice Λ_n

We call a partition of the set $\{1, 2, \dots, n\}$ *non-trivial* if it is neither indiscrete nor discrete: that is, the number of equivalence classes is greater than 1 but less than n . The non-trivial partitions, ordered by refinement, form a lattice. We use the notation Λ_n both for this lattice and for the simplicial complex which is its nerve.

Proposition 2.7 *The nerve Λ_n of the partition lattice is Σ_n -equivariantly homeomorphic to the space T_n of fully-grown n -trees.*

Proof We describe an explicit homeomorphism $\varphi: T_n \rightarrow \Lambda_n$. A point $\alpha \in T_n$ is an n -tree in which each internal edge has a given length between 0 and 1.

For each $1 \leq i \leq n$ there is a unique arc γ_i in the tree α which starts at the root labelled 0 and ends at the leaf labelled i . We parametrize all these arcs with unit speed, and we extend γ_i to a map $[0, \infty) \rightarrow \alpha$ by setting $\gamma_i(t)$ to be constant at the vertex labelled i for all $t \gg 0$.

As time increases, these arcs diverge and determine finer and finer partitions of $\{1, 2, \dots, n\}$. For every $t > 0$ we define $\Pi_\alpha(t)$ to be the partition of $\{1, 2, \dots, n\}$ given by the equivalence relation

$$i \sim j \iff \gamma_i(t) = \gamma_j(t).$$

The partition $\Pi_\alpha(t)$ refines $\Pi_\alpha(s)$ if $t > s$. Further, $\Pi_\alpha(t)$ is discrete for all sufficiently large t ; and it is indiscrete when t is sufficiently close to zero. Hence there is a unique affine map $\rho: [0, 1] \rightarrow [0, \infty)$ such that $\Pi_\alpha(\rho(t))$ is non-trivial exactly for $0 < t < 1$.

We can now define the point $\varphi(\alpha)$ in the nerve Λ_n of the partition lattice, as follows. The barycentric coordinate of $\varphi(\alpha)$ with respect to any non-trivial partition Π is to be the length of the interval $\{t \in [0, 1] \mid \Pi_\alpha(\rho(t)) = \Pi\}$. The map $\varphi: T_n \rightarrow \Lambda_n$ so defined is a homeomorphism because the fully-grown tree α is uniquely determined by its one-parameter family of partitions Π_α . The map is clearly equivariant. \square

Corollary 2.8 *The right action of Σ_n on the nerve of the partition lattice Λ_n extends to a right action of Σ_{n+1} .*

Proof This is true of the action on T_n , since the action of Σ_n there is the restriction of the action of the group Σ_{n+1} of permutations of the full set $\{0, 1, \dots, n\}$ of labels. \square

3 The representation \mathfrak{S}_n and the fundamental cycle

3.1 The Lie representations

Let \mathcal{L}_n be the free Lie ring on the set of generators $\{x_i\}_{1 \leq i \leq n}$. We denote by Lie_n the n -linear part of \mathcal{L}_n . This can be described in many different ways. First, it is the direct summand of \mathcal{L}_n spanned by all Lie monomials containing each of the n generators exactly once. Second, it is isomorphic to the module of all natural transformations $\Phi^{\otimes n} \rightarrow \Phi$, where Φ is the forgetful functor from Lie rings to abelian groups. Third, it is the n th module in the Lie operad.

It is a standard exercise in the use of the Jacobi identity to show that Lie_n is a free abelian group of rank $(n-1)!$, and that the left-regulated Lie brackets

$$\lambda_\sigma = [x_{\sigma(1)}, [x_{\sigma(2)}, [\dots [x_{\sigma(n-1)}, x_n] \dots]]]$$

for $\sigma \in \Sigma_{n-1}$ form a \mathbb{Z} -basis for Lie_n (see for example [7] or [13]). The symmetric group Σ_n acts on Lie_n on the left by permuting the n generators. The (integral) representation thus afforded is known as the *Lie representation*. The subgroup Σ_{n-1} permutes the above standard basis simply and transitively. Thus the restricted representation $\text{Res}_{\Sigma_{n-1}}^{\Sigma_n} \text{Lie}_n$ is the regular integral representation of Σ_{n-1} .

We denote by Lie_n^* the dual representation $\text{Hom}(\text{Lie}_n, \mathbb{Z})$. This has the same character as Lie_n , and therefore Lie_n and Lie_n^* are isomorphic over the rationals. Over the integers, the two are distinct.

Example 3.2

Take $n = 3$, and consider the essentially unique Σ_3 -invariant Euclidean metric on the two-dimensional space $\text{Lie}_3 \otimes \mathbb{R}$. Both Lie_3 and Lie_3^* are hexagonal lattices in this (self-dual) Euclidean space. However, in Lie_3 the shortest vectors have the form $[x_i, [x_j, x_k]]$, and so these are (-1) -eigenvectors of involutions $(j, k) \in \Sigma_3$. In Lie_3^* the shortest vectors are $(+1)$ -eigenvectors of involutions.

Let ε denote the sign character of Σ_n . Then we have the twisted module εLie_n which is the same abelian group Lie_n with the twisted action of Σ_n defined by

$$\sigma \cdot f(x_1, \dots, x_n) = \varepsilon(\sigma) f(x_{\sigma(1)}, \dots, x_{\sigma(n)})$$

for every multilinear Lie monomial f and every $\sigma \in \Sigma_n$. We also denote the module εLie_n by $\varepsilon \otimes \text{Lie}_n$ when we need to stress that it is the tensor product with the sign module. We similarly have the twisted representation $\varepsilon \text{Lie}_n^*$, defined analogously.

3.3 Connection with Lie superrings

There is a reinterpretation of the module εLie_n which significantly simplifies our theory. In place of the free Lie ring on the set of generators $\{x_i\}_{1 \leq i \leq n}$ we may consider the free Lie superring (or Lie superalgebra over \mathbb{Z}) having the x_i as odd-degree generators. This we denote by \mathcal{S}_n . It is a graded algebra $\mathcal{S}_n^{\text{even}} \oplus \mathcal{S}_n^{\text{odd}}$ freely generated by the x_i subject to the relations

$$\begin{aligned} [a, b] &= (-1)^{|a||b|+1}[b, a] \\ [[a, b], c] &= [a, [b, c]] - (-1)^{|a||b|}[b, [a, c]] \end{aligned}$$

when a and b are homogeneous elements of degrees $|a|$ and $|b|$ respectively.

Let \mathfrak{S}_n denote the *super-Lie representation* of Σ_n . This we define to be the n -linear part of \mathcal{S}_n : it is spanned by the super-Lie monomials containing each x_i exactly once, and is a subgroup of $\mathcal{S}_n^{\text{even}}$ or $\mathcal{S}_n^{\text{odd}}$ according to the parity of n . The symmetric group acts by permuting the generators, exactly as in the Lie representation. We now determine the structure of \mathfrak{S}_n .

Proposition 3.4 *The super-Lie representation \mathfrak{S}_n and the twisted Lie representation εLie_n are isomorphic Σ_n -modules.*

Proof The module Lie_n is spanned by all Lie monomials $g(x_1, x_2, \dots, x_n)$ in which each of the n generators occurs once. The n variables occur in g in a definite order: let this order, reading from left to right, be $x_{\gamma(1)}, x_{\gamma(2)}, \dots, x_{\gamma(n)}$. This gives a permutation $\gamma \in \Sigma_n$ depending upon g . Every such g is the bracket $[h, k]$ of two monomials in complementary subsets of the variables.

Let \mathcal{J} be any Lie superring, and y_1, y_2, \dots, y_n any elements of odd degree in \mathcal{J} . We claim that there is a unique homomorphism $\Theta : \text{Lie}_n \rightarrow \mathcal{J}$ of abelian groups such that for each monomial $g(x_1, x_2, \dots, x_n)$ as above

$$\Theta(g(x_1, x_2, \dots, x_n)) = \varepsilon(\gamma)G(y_1, y_2, \dots, y_n)$$

where $G(y_1, y_2, \dots, y_n)$ is the element of \mathcal{J} obtained by replacing all the Lie bracket operators in g by Lie superbrackets, then substituting y_i for x_i ; and $\varepsilon(\gamma)$ is the sign of $\gamma(g)$. The uniqueness of Θ is clear.

We construct Θ by induction on n . Suppose the result is known already for fewer than n generators. Then if g has n variables and $g = [h, k]$ as above, we have $\Theta(g) = \eta \cdot [\Theta(h), \Theta(k)]$ where $[\Theta(h), \Theta(k)]$ is the superbracket and η is the sign of the inverse shuffle which places the generators occurring in h before those occurring in k . In order to show that Θ is a well-defined homomorphism in the

n -variables case, we must verify that it respects the antisymmetry and Jacobi relations $[h, k] = -[k, h]$ and $[h, [k, l]] + [k, [l, h]] + [l, [h, k]] = 0$ of Lie_n . But this is true because the shuffle signs convert these relators into the corresponding signed relators, which are zero in the Lie superring \mathcal{J} . The induction is now complete.

It is not at all difficult to give an instance where Θ is a monomorphism: one begins by taking the y_i to be elementary matrices representing elements of the endomorphism superring of a superspace of large rank. Therefore Θ is also a monomorphism when \mathcal{J} is the free superring generated by the odd-degree elements y_1, y_2, \dots, y_n . So in this case Θ is an isomorphism of abelian groups onto its image, which is \mathfrak{S}_n . For any $\sigma \in \Sigma_n$ we have

$$\Theta(\sigma \cdot g) = \varepsilon(\sigma\gamma)(\sigma \cdot G) = \varepsilon(\sigma)(\sigma \cdot \Theta(g)) .$$

Hence Θ induces an isomorphism between Lie_n and $\varepsilon \otimes \mathfrak{S}_n$, and between εLie_n and \mathfrak{S}_n . \square

The construction of the isomorphism between εLie_n and \mathfrak{S}_n makes use of the natural ordering of the set x_1, x_2, \dots, x_n of generators. The effect of adopting a different fundamental ordering, related to the natural one by a permutation τ , is to multiply the isomorphism by the sign of τ . When the set of generators is unordered, the isomorphism is uniquely defined only up to sign.

Corollary 3.5 *The left-regulated Lie superbrackets*

$$\lambda_\sigma = [x_{\sigma(1)}, [x_{\sigma(2)}, [\dots [x_{\sigma(n-1)}, x_n] \dots]] ,$$

where $\sigma \in \Sigma_{n-1}$, form a basis for \mathfrak{S}_n .

Proof This follows from 3.1 and 3.4, or by direct computation as for Lie_n . \square

The first advantage of \mathfrak{S}_n over εLie_n in our homology theory is that the Lie superbracket is extremely useful in building the fundamental orientation cycle. The second advantage is that the isomorphism of \mathfrak{S}_n with the cohomology of T_n , which we shall construct in Theorem 4.1 below, is totally natural: it does not depend upon an ordering of the set of non-zero labels.

3.6 Construction of the fundamental cycle

We now describe the construction of a certain cycle F_n in the top-dimensional simplicial chain group $C_{n-3}(T_n; \mathfrak{S}_n)$, which after 3.4 we know to be isomorphic to $C_{n-3}(T_n; \varepsilon \text{Lie}_n)$. A top-dimensional simplex X of T_n is an n -tree which is *binary*; that is, every internal node is the meet of three edges (see §2). The vertices of the simplex correspond to the internal edges of the tree X ; so an orientation of the simplex may be specified by a word $w_X = e_0 e_1 \dots e_{n-3}$ in which each internal edge of X appears once. We write this oriented simplex $\langle w_X \rangle$. If the order of the edges in w_X is altered by a permutation σ , then $\langle w_X \rangle$ is multiplied by $\varepsilon(\sigma)$. We shall choose such an ordering for each $(n - 3)$ -simplex X of T_n , and we shall set

$$F_n = \sum_X \langle w_X \rangle \otimes c_X \in C_{n-3}(T_n; \mathfrak{S}_n)$$

where $c_X \in \mathfrak{S}_n$ is a coefficient monomial which we now describe.

We use induction on n to define w_X and c_X . When $n \leq 2$ the complex T_n is empty, as the unique n -trees X have no internal edges; but nevertheless we formally define $c_X = x_1$ when $n = 1$ and $c_X = -[x_1, x_2]$ when $n = 2$. Here, and throughout the rest of §3, the bracket is the operation in a free Lie *superring*. The variables x_i are in bijective correspondence with the non-zero tree labels. Since the x_i are assigned odd grading, we have $[x_1, x_2] = [x_2, x_1]$. The total ordering on the set of labels has no significance.

We continue with our inductive definition. Suppose now that $n > 2$.

The n -tree X is obtained by grafting together at the root an i -tree Y and an $(n - i)$ -tree Z , where $0 < i < n$, as in the following diagram

since the root of X meets two other edges. The internal edges of X comprise the internal edges of Y and those of Z , together with the roots ρ_Y and ρ_Z of Y and Z . Suppose by induction that we have well-defined terms $\langle w_Y \rangle \otimes c_Y$ and $\langle w_Z \rangle \otimes c_Z$ corresponding to orderings of the internal edges of Y and Z , the

coefficients c_Y and c_Z being super-Lie monomials in the sets of non-zero labels of Y and Z respectively. We set $w_X = \rho_Y w_Y \rho_Z w_Z$, this being an ordering of all the internal edges of X . The set of non-zero labels of X is the disjoint union of those of Y and Z . We put $c_X = (-1)^{|Y|}[c_Y, c_Z]$ where $|Y|$ is the number i of leaves, excluding the root, in Y . This is a super-Lie monomial in the non-zero labels of X .

To justify this construction, we verify in the next two lemmas that $\langle w_X \rangle \otimes c_X$ is a well-defined element of the chain group $C_{n-3}(T_n; \mathfrak{S}_n)$, and that the sum F_n of these elements over all top-dimensional simplices X is a cycle.

Lemma 3.7 *The term*

$$\langle w_X \rangle \otimes c_X \in C_{n-3}(T_n; \mathfrak{S}_n)$$

is well defined for every binary n -tree X , and is Σ_n -invariant.

Proof We again use induction on n . For $n = 1$ the result is completely trivial. When $n \geq 2$ the tree X is obtained by grafting to the root an i -tree Y and an $(n - i)$ -tree Z , where $0 < i < n$ and therefore both $\langle w_Y \rangle \otimes c_Y$ and $\langle w_Z \rangle \otimes c_Z$ are well-defined by inductive hypothesis.

Since the oriented simplices $\langle w_Y \rangle$ and $\langle w_Z \rangle$ are evidently well defined up to sign, the coefficients c_Y and c_Z are well defined up to sign. Therefore the total sign in the formula

$$\langle w_X \rangle \otimes c_X = \langle \rho_Y w_Y \rho_Z w_Z \rangle \otimes (-1)^{|Y|}[c_Y, c_Z]$$

is independent of the orientations of the two simplices Y and Z , by bilinearity of tensor product. The only remaining ambiguity is that the sub-trees Y and Z can be listed in either order. Interchanging them may affect the orientation of the simplex X , and may alter the sign of $c_X = (-1)^{|Y|}[c_Y, c_Z]$.

We compute the change in the total sign when Y and Z are interchanged. Since the number of internal edges in a binary tree equals the number of leaves (excluding the root) less two, the effect of interchanging $\rho_Y w_Y$ and $\rho_Z w_Z$ is to multiply $\langle w_X \rangle$ by the sign $(-1)^{(i-1)(n-i-1)}$. On the other hand, the replacement of $(-1)^{|Y|}$ by $(-1)^{|Z|}$ introduces a sign $(-1)^n$, whilst the replacement of the superbracket $[c_Y, c_Z]$ by $[c_Z, c_Y]$ gives a factor $(-1)^{i(n-i)+1}$, because c_Y and c_Z have degrees i and $n - i$ respectively. The product of these four signs is $+1$, so that $\langle w_X \rangle \otimes c_X$ is independent of the order in which Y and Z are taken. The inductive step is thus complete. Finally, the Σ_n -invariance of $\langle w_X \rangle \otimes c_X$ is obvious, since the ordering of the set of labels has nowhere been used. The lemma is proved. □

Proposition 3.8 *The $(n - 3)$ -chain*

$$F_n = \sum_X \langle w_X \rangle \otimes c_X \in C_{n-3}(T_n; \mathfrak{S}_n)$$

is a Σ_n -invariant cycle.

Proof The Σ_n -invariance of F_n follows from Lemma 3.7.

To prove that F_n is a cycle, we calculate all the coefficients of the $(n - 4)$ -chain ∂F_n . Every oriented $(n - 4)$ -simplex σ corresponds to a tree S which is binary apart from one exceptional node, where four edges meet. There are two cases, depending upon the position of the exceptional node.

Suppose first that the exceptional node is the root node. Then S is the result of grafting together three trees X , Y and Z , as shown on the left here. As orientation for σ we may take the edge-sequence $\langle \rho_X w_X \rho_Y w_Y \rho_Z w_Z \rangle$, since this lists all the internal edges (in the notation of 3.6). One of the three $(n - 3)$ -simplices incident upon σ is obtained by grafting X to Y (which introduces a new root ρ_{XY}) and grafting the result to Z , as in the picture on the right.

This simplex can be oriented as $\langle \rho_{XY} \rho_X w_X \rho_Y w_Y \rho_Z w_Z \rangle$: then its incidence index upon σ is $+1$, and its contribution to the coefficient of ∂F_n on σ is, by two applications of the construction in 3.6

$$(-1)^{|Y|} [[c_X, c_Y], c_Z].$$

The other two $(n - 3)$ -simplices incident on σ are obtained from the first by permuting X , Y and Z cyclically. The simplex $\langle \rho_Y z \rho_Y w_Y \rho_Z w_Z \rho_X w_X \rangle$ has incidence index $(-1)^{(|X|+1)(|Y|+|Z|)}$ upon σ (oriented as before), and the applications of the construction of 3.6 contribute altogether a sign $(-1)^{|Z|}$. The second simplex therefore contributes

$$(-1)^{|Y|+|X||Y|+|X||Z|} [[c_Y, c_Z], c_X].$$

By cyclic permutation, the third simplex incident upon σ contributes

$$(-1)^{|Y|+|Z||X|+|Z||Y|}[[c_Z, c_X], c_Y].$$

The total coefficient of ∂F_n on σ is thus zero in view of the Jacobi identity

$$(-1)^{|Y||Z|}[[c_Z, c_X], c_Y] + (-1)^{|Z||X|}[[c_X, c_Y], c_Z] + (-1)^{|X||Y|}[[c_Y, c_Z], c_X] = 0$$

in the Lie superring. The first case is proved.

In the second case, the exceptional node (where four edges meet) of S is not the root node. Thus S is obtained by grafting together at the root a binary tree T and a tree U having one exceptional node. Let m be the number $|U|$ of leaves of U . It follows by application of the definition in 3.6 that the coefficient of ∂F_n on σ is $[c_T, e]$ where e is the coefficient of ∂F_m on an appropriate orientation of the simplex represented by U . By induction on n , we know that F_m is a cycle, so e is zero. This establishes the second case, and completes the proof of 3.8. □

Example 3.9

We illustrate the foregoing theory by calculating the fundamental cycle F_5 of T_5 . To reinforce the point that the ordering of the tree labels is nowhere used, we label the trees by $\{0, a, b, c, d, e\}$ in place of $\{0, 1, 2, 3, 4, 5\}$. We use a, b, c, d, e also to denote the corresponding odd-degree generators of the Lie superring.

We enumerate the top-dimensional simplices of T_5 . There are 105 of these, generated by the trees pictured here and the action of the symmetric group Σ_5 on the labels a, b, c, d, e . We choose orientations for the simplices by ordering the internal edges, and then calculate the 105 corresponding terms in the cycle F_5 . Each term is obtained by using the formula of 3.6 twice.

There are 60 terms of the form $\Phi = \langle x, y, z \rangle \otimes [a, [b, [c, [d, e]]]]$ corresponding to trees of the shape:

another 30 terms of the form $\Psi = -\langle p, q, r \rangle \otimes [[a, b], [c, [d, e]]]$ corresponding to trees of the shape:

and 15 terms of the form $\Omega = -\langle i, j, k \rangle \otimes [a, [[b, c], [d, e]]]$ corresponding to trees of the shape:

The number of terms in each case is given by dividing $5! = 120$ by the order of the symmetry group of the tree fixing the root. Our construction takes care of the signs. We have

$$F_5 = \sum \langle x, y, z \rangle \otimes [a, [b, [c, [d, e]]]] - \sum \langle p, q, r \rangle \otimes [[a, b], [c, [d, e]]] - \sum \langle i, j, k \rangle \otimes [a, [[b, c], [d, e]]]$$

where there are 105 terms in all, corresponding to all the labelled trees up to label-preserving isomorphism. (The letters attached to the internal edges are bound variables over which summation is carried out: other symbols can be substituted for them at will.) Now we check that the boundary ∂F_5 is zero. We revert to the notation Φ, Ψ, Ω for the three types of terms in F_5 . On each type there are three face operators to consider.

First we look at the terms $\partial_2 \Phi$. We have $\partial_2 \Phi = \langle x, y \rangle \otimes [[a, b], [c, [d, e]]]$ where $\langle x, y \rangle$ is an orientation of the tree:

in which the leaves c, d and e are attached at the same node. Therefore the 60 terms $\partial_2\Phi$ cancel among themselves in threes by virtue of the relation

$$[c, [d, e]] + [d, [e, c]] + [e, [c, d]] = 0$$

in the coefficient module \mathfrak{S}_5 . In the same way, the 30 terms $\partial_2\Psi$ have sum zero, and the 60 terms $\partial_0\Phi$ cancel the 30 terms $\partial_0\Psi$ by the supercommutator formula

$$[[a, b], [c, [d, e]]] - [a, [b, [c, [d, e]]]] - [b, [a, [c, [d, e]]]] = 0.$$

Finally each of the 15 terms $\partial_0\Omega$ cancels with a pair of terms $\partial_1\Psi$ through

$$[a, [[b, c], [d, e]]] = [[b, c], [a, [d, e]]] - [[d, e], [a, [b, c]]]$$

and each of the terms in $\partial_1\Omega$ or $\partial_2\Omega$ likewise cancels a pair of terms in $\partial_1\Phi$. This accounts for all 315 terms in ∂F_5 , and verifies that F_5 is a cycle.

4 The homology and cohomology as integral representations of Σ_n

We showed in §2 that the space T_n has reduced homology only in dimension $n - 3$. We now determine the action of Σ_n on this finite \mathbb{Z} -module. The following theorem is equivalent to a result proved by M. Wachs [12] for the cohomology of the poset of partitions.

Theorem 4.1 *There are isomorphisms of left Σ_n -modules and of right Σ_n -modules respectively*

$$\begin{aligned} \tilde{H}^*(T_n; \mathbb{Z}) &\approx \mathfrak{S}_n \approx \varepsilon \text{Lie}_n \\ \tilde{H}_*(T_n; \mathbb{Z}) &\approx \mathfrak{S}_n^* \approx \varepsilon \text{Lie}_n^*. \end{aligned}$$

Proof As T_n is a finite complex with torsion-free homology, there is for every coefficient group G a natural universal coefficient isomorphism

$$\tilde{H}_*(T_n; G) \approx \text{Hom}_{\mathbb{Z}}(\tilde{H}^*(T_n), G).$$

In particular, the integral homology and integral cohomology are dual \mathbb{Z} -modules. In the above we take G to be \mathfrak{S}_n or the isomorphic module εLie_n . The homology class of the invariant cycle F_n constructed in 3.6 corresponds under the universal coefficient isomorphism to some homomorphism $\theta_n: \tilde{H}^*(T_n) \rightarrow \mathfrak{S}_n$, which is indeed Σ_n -equivariant because the universal coefficient isomorphism is natural and F_n is Σ_n -invariant.

Let f_σ be the cocycle of T_n which takes the value 1 on the simplex γ_σ depicted in 2.5, and is zero on all other $(n - 3)$ -simplices of T_n . Then the set

$$\{[f_\sigma] \mid \sigma \in \Sigma_{n-1}\}$$

is a basis for $\tilde{H}^*(T_n)$, by 2.5. The value of θ_n on $[f_\sigma]$ is $\pm\lambda_\sigma$, by 3.6 and induction on n , where λ_σ is the basis element $[x_{\sigma(1)}, [x_{\sigma(2)}, [\dots [x_{\sigma(n-1)}, x_n] \dots]]$ of the \mathbb{Z} -module \mathfrak{S}_n , as in 3.5. Therefore we have shown that the Σ_n -homomorphism θ_n carries a basis for $\tilde{H}^*(T_n)$ into a basis for \mathfrak{S}_n , which is isomorphic to εLie_n by 3.4. That proves the first assertion in the theorem. The second assertion follows by taking \mathbb{Z} -duals. \square

Corollary 4.2 *The Σ_n -module Lie_n is the restriction of a left Σ_{n+1} -module.*

Proof We have seen that Σ_{n+1} acts on T_n , so it acts upon $\varepsilon \tilde{H}^*(T_n)$, which is isomorphic to Lie_n . \square

Definition 4.3 We denote by $\widehat{\text{Lie}}_n$ the left Σ_{n+1} -module so defined, and by $\widehat{\text{Lie}}_n^*$ the dual right Σ_{n+1} -module. Evidently $\text{Res}_{\Sigma_n}^{\Sigma_{n+1}} \widehat{\text{Lie}}_n \approx \text{Lie}_n$.

5 The Whitehouse extension

Let H be a subgroup of the finite group G . Since the functor Ind_H^G is left adjoint to Res_H^G , there is an adjunction morphism $\text{Ind}_H^G \text{Res}_H^G M \rightarrow M$ for every G -module M , and it is always surjective.

The following theorem was proved algebraically by Whitehouse [13]; it also follows from work of Sundaram [10].

Theorem 5.1 *There is a short exact sequence of Σ_{n+1} -modules*

$$0 \longrightarrow \text{Lie}_{n+1}^* \longrightarrow \text{Ind}_{\Sigma_n}^{\Sigma_{n+1}} \text{Lie}_n^* \longrightarrow \widehat{\text{Lie}}_n^* \longrightarrow 0$$

in which the surjection is the adjunction morphism connecting $\text{Ind}_{\Sigma_n}^{\Sigma_{n+1}}$ and $\text{Res}_{\Sigma_n}^{\Sigma_{n+1}}$.

We shall give a topological proof. We recall that there is an analogue for G -spaces of the induction functor Ind_H^G , namely smash product with $(G/H)_+$. Theorem 5.1 follows immediately from the cofibration in the following theorem, by taking reduced homology.

Theorem 5.2 *There is a Σ_{n+1} -equivariant cofibration*

$$X \subset T_{n+1} \longrightarrow (\Sigma_{n+1}/\Sigma_n)_+ \wedge ST_n$$

where X is Σ_{n+1} -homotopy equivalent to T_n and S denotes suspension.

Proof In the tree space T_{n+1} we consider for each $1 \leq i \leq n+1$ the star $\text{st}(v_{0i})$ of the vertex v_{0i} of 2.2. This consists of all the $(n+1)$ -trees in which the leaves labelled 0 and i are separated from the rest of the tree by an internal edge of positive length. These $n+1$ open stars are therefore disjoint. The closure $\overline{\text{st}}(v_{0i})$ is isomorphic to the contractible space \tilde{T}_n , by the homeomorphism which deletes the leaf 0 and then relabels the leaf $n+1$ as 0. Let X be the complement $T_{n+1} \setminus \bigcup_{i=1}^{n+1} \text{st}(v_{0i})$. By 2.3 the subcomplex \tilde{T}_n is the cone on T_n , so

$$T_{n+1}/X \approx \bigvee_{i=1}^{n+1} \overline{\text{st}}(v_{0i})/\partial(\overline{\text{st}}(v_{0i})) \approx \bigvee_{i=1}^{n+1} ST_n .$$

The isomorphism $\overline{\text{st}}(v_{0,n+1})/\partial(\overline{\text{st}}(v_{0,n+1})) \approx ST_n$ is Σ_n -equivariant, and Σ_{n+1} induces a bijection between the summands and the left cosets Σ_{n+1}/Σ_n , so the wedge on the right above is equivariantly isomorphic to $(\Sigma_{n+1}/\Sigma_n)_+ \wedge ST_n$.

We must now prove that X is Σ_{n+1} -homotopy-equivalent to T_n , where Σ_{n+1} acts on T_n by permuting the labels $\{0, 1, \dots, n\}$, with 0 in place of $n+1$. We assume $n \geq 3$: the reasoning below requires trivial modifications for $n = 1, 2$.

Given any tree in T_n , we obtain a tree in $X \subset T_{n+1}$ by the following procedure: relabel the leaf 0 as $n+1$, then attach a new leaf labelled 0 at any point on any *internal* edge. Every point of X arises once only in this way, so the reverse procedure (deleting the leaf 0 and relabelling the leaf $n+1$ as 0) gives a projection $\varphi: X \rightarrow T_n$. As usual, when the leaf-deletion results in the

amalgamation of two edges with lengths x and y , the new combined edge is assigned length $\max(x, y)$.

The inverse image under φ of any point $t \in T_n$ is isomorphic to the subtree consisting of the internal edges of t . This is contractible. By the Vietoris Theorem 5.3 below, φ is a homotopy equivalence.

The map φ is Σ_{n+1} -equivariant by construction. To show that it is a equivariant homotopy equivalence, it suffices to show that, for every subgroup H of Σ_{n+1} , the restriction $\varphi^H: X^H \rightarrow T_n^H$ between the fixed point sets is a homotopy equivalence. If $t \in T_n^H$ is any H -fixed point, then the group H acts by isometries on the tree t , permuting the labels.

Whenever a finite group acts by isometries on a finite tree, the set of invariant points is contractible. In our case the invariant points form the inverse image of the point t under φ^H . Thus φ^H satisfies the hypotheses of Theorem 5.3, and the induced map of fixed point sets is always a homotopy equivalence, which proves Theorem 5.2 and therefore Theorem 5.1. \square

The Vietoris theorem used in the above proof was proved in the following strong form by M. M. Cohen ([5], Theorem 11.1).

Theorem 5.3 *A piecewise linear map between finite polyhedra is a simple homotopy equivalence if the inverse image of every point is contractible.* \square

Homotopy equivalence under these hypotheses is a theorem of Smale [9]. The simply connected case already follows from Vietoris [11] by an application of Whitehead's Theorem.
