

## $Z_2^k$ -actions fixing $\mathbb{R}P^2 \cup \mathbb{R}P^{\text{even}}$

ROGÉRIO DE OLIVEIRA  
PEDRO L Q PERGHER  
ADRIANA RAMOS

This paper determines, up to equivariant cobordism, all manifolds with  $Z_2^k$ -action whose fixed point set is  $\mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $n > 2$  is even.

57R85; 57R75

### 1 Introduction

Suppose  $M$  is a smooth, closed manifold and  $T: M \rightarrow M$  is a smooth involution defined on  $M$ . It is well known that the fixed point set  $F$  of  $T$  is a finite and disjoint union of closed submanifolds of  $M$ . For a given  $F$ , a basic problem in this context is the classification, up to equivariant cobordism, of the pairs  $(M, T)$  for which the fixed point set is  $F$ . For related results, see for example Royster [16], Hou and Torrence [6; 7], Pergher [11], Stong [17; 18], Conner and Floyd [4, Theorem 27.6], Kosniowski and Stong [8, page 309] and Lü [9; 10].

For  $F = \mathbb{R}P^n$ , the classification was established in [4] and [17]. DC Royster [16] then studied this problem with  $F$  the disjoint union of two real projective spaces,  $F = \mathbb{R}P^m \cup \mathbb{R}P^n$ . He established the results via a case-by-case method depending on the parity of  $m$  and  $n$ , with special arguments when one of the components is  $\mathbb{R}P^0 = \{\text{point}\}$ , but his methods were not sufficient to handle the case when  $m$  and  $n$  are even and positive. If  $m$  and  $n$  are even and  $m = n$ , one knows from [8] that  $(M, T)$  is an equivariant boundary when  $\dim(M) \geq 2n$ ; it was later shown in [7] that  $(M, T)$  also is a boundary when  $n \leq \dim(M) < 2n$ . To understand the case  $(m, n) = (0, \text{even})$  and also the goal of this paper, consider the involution  $(\mathbb{R}P^{m+n+1}, T_{m,n})$ , for any  $m$  and  $n$ , defined in homogeneous coordinates by

$$T_{m,n}[x_0, x_1, \dots, x_{m+n+1}] = [-x_0, -x_1, \dots, -x_m, x_{m+1}, \dots, x_{m+n+1}].$$

The fixed set of  $T_{m,n}$  is  $\mathbb{R}P^m \cup \mathbb{R}P^n$ . From  $T_{m,n}$ , it may be possible to obtain other involutions fixing  $\mathbb{R}P^m \cup \mathbb{R}P^n$ : in general, for a given involution  $(W, T)$  with fixed

set  $F$  and  $W$  a boundary, the involution

$$\Gamma(W, T) = \left( \frac{S^1 \times W}{-\text{Id} \times T}, \tau \right)$$

is equivariantly cobordant to an involution fixing  $F$ ; here,  $S^1$  is the 1–sphere,  $\text{Id}$  is the identity map and  $\tau$  is the involution induced by  $c \times \text{Id}$ , where  $c$  is complex conjugation (see Conner and Floyd [5]). If  $(S^1 \times W)/(-\text{Id} \times T)$  is a boundary, we can repeat the process taking  $\Gamma^2(W, T)$ , and so on. If  $F$  is nonbounding, this process finishes, that is, there exists a smallest natural number  $r \geq 1$  for which the underlying manifold of  $\Gamma^r(W, T)$  is nonbounding; this follows from the  $(5/2)$ –theorem of J Boardman in [1] and its strengthened version in [8]. In particular, if  $m$  and  $n$  are even and  $m < n$ ,  $\mathbb{R}P^m \cup \mathbb{R}P^n$  does not bound and  $\mathbb{R}P^{m+n+1}$  bounds, so this number  $r$  makes sense for  $(\mathbb{R}P^{m+n+1}, T_{m,n})$ , and we denote  $r$  by  $h_{m,n}$ . In [16], Royster proved the following theorem:

**Theorem** *Let  $(M, T)$  be an involution fixing  $\{\text{point}\} \cup \mathbb{R}P^n$ , where  $n$  is even. Then  $(M, T)$  is equivariantly cobordant to  $\Gamma^j(\mathbb{R}P^{n+1}, T_{0,n})$  for some  $0 \leq j \leq h_{0,n}$ .*

Later, in [15], R E Stong and P Pergher determined the value of  $h_{0,n}$ , thus answering the question posed by Royster in [16, page 271]: writing  $n = 2^p q$  with  $p \geq 1$  and  $q \geq 1$  odd, they showed that  $h_{0,n} = 2$  if  $p = 1$  and  $h_{0,n} = 2^p - 1$  if  $p > 1$ .

In this paper, we contribute to this problem by solving the case  $(m, n) = (2, \text{even})$ . Specifically, we will prove the following:

**Theorem 1** *Let  $(M, T)$  be an involution fixing  $\mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $M$  is connected and  $n \geq 4$  is even. If  $n > 4$ , then  $(M, T)$  is equivariantly cobordant to  $\Gamma^j(\mathbb{R}P^{n+3}, T_{2,n})$  for some  $0 \leq j \leq h_{2,n}$ . If  $n = 4$ , then  $(M, T)$  is either equivariantly cobordant to  $\Gamma^j(\mathbb{R}P^7, T_{2,4})$  for some  $0 \leq j \leq h_{2,4}$ , or equivariantly cobordant to  $\Gamma^2(\mathbb{R}P^3, T_{0,2}) \cup (\mathbb{R}P^5, T_{0,4})$ .*

In addition, we generalize the result of Stong and Pergher of [15], calculating the general value of  $h_{m,n}$  (which, in particular, makes numerically precise the statement of Theorem 1).

**Theorem 2** *For  $m, n$  even,  $0 \leq m < n$ , write  $n - m = 2^p q$  with  $p \geq 1$  and  $q \geq 1$  odd. Then  $h_{m,n} = 2$  if  $p = 1$ , and  $h_{m,n} = 2^p - 1$  if  $p > 1$ .*

Finally, we also extend the results for  $Z_2^k$ –actions. This extension is automatic from the combination of the above results and the case  $F = \mathbb{R}P^{\text{even}}$  with a recent paper of the

first two authors [13]. The details concerning this extension will be given in Section 4. Section 2 and Section 3 will be devoted, respectively, to the proofs of Theorem 1 and Theorem 2.

**Acknowledgements** The authors would like to thank Professor Robert E Stong of the University of Virginia for suggestions and techniques. The second author was partially supported by CNPq and FAPESP, and the third was supported by CAPES.

## 2 Involutions fixing $\mathbb{R}P^2 \cup \mathbb{R}P^{\text{even}}$

We start with an involution  $(M, T)$  fixing  $\mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $M$  is connected and  $n \geq 4$  is even, and first establish some notations. We will always use  $\lambda_r \rightarrow \mathbb{R}P^r$  to denote the canonical line bundle over  $\mathbb{R}P^r$ . Denote by  $\alpha \in H^1(\mathbb{R}P^2, Z_2)$  and  $\beta \in H^1(\mathbb{R}P^n, Z_2)$  the generators of the 1-dimensional  $Z_2$ -cohomology. The model involution  $(\mathbb{R}P^{n+3}, T_{2,n})$  fixes  $\mathbb{R}P^2 \cup \mathbb{R}P^n$  with normal bundles  $(n+1)\lambda_2 \rightarrow \mathbb{R}P^2$  and  $3\lambda_n \rightarrow \mathbb{R}P^n$ . The total Stiefel-Whitney classes are  $W((n+1)\lambda_2) = (1+\alpha)^{n+1}$ ,  $W(3\lambda_n) = (1+\beta)^3$ . Denote by  $\eta \rightarrow \mathbb{R}P^2$  and  $\xi \rightarrow \mathbb{R}P^n$  the normal bundles of  $\mathbb{R}P^2$  and  $\mathbb{R}P^n$  in  $M$ . To prove Theorem 1, it suffices to prove the following:

**Lemma 3** *If  $n > 4$ , then  $W(\eta) = (1+\alpha)^{n+1}$  and  $W(\xi) = (1+\beta)^3$ . If  $n = 4$ , then either  $W(\eta) = (1+\alpha)^5$  and  $W(\xi) = (1+\beta)^3$ , or  $W(\eta) = 1+\alpha$  and  $W(\xi) = 1+\beta$ .*

In fact, suppose Lemma 3 is true, and denote by  $R$  the trivial one-dimensional vector bundle over any base space. Set  $k = \dim(\eta)$  and  $l = \dim(\xi)$ , that is,  $k = \dim(M) - 2$  and  $l = \dim(M) - n \geq 1$ .

First consider  $n > 4$ . By [5], for  $0 \leq j \leq h_{2,n}$ , the involution  $\Gamma^j(\mathbb{R}P^{n+3}, T_{2,n})$  is equivariantly cobordant to an involution with fixed data

$$((n+1)\lambda_2 \oplus jR \rightarrow \mathbb{R}P^2) \cup (3\lambda_n \oplus jR \rightarrow \mathbb{R}P^n).$$

Using the notations  $W = 1 + w_1 + w_2 + \dots$  for Stiefel-Whitney classes and  $\binom{a}{b}$  for binomial coefficients mod 2, note that  $w_3(\xi) = \binom{3}{3}\beta^3 = \beta^3 \neq 0$  and thus  $l \geq 3$ . Then

$$\eta \cup \xi \quad \text{and} \quad ((n+1)\lambda_2 \oplus (l-3)R) \cup (3\lambda_n \oplus (l-3)R)$$

are cobordant because they have the same characteristic numbers. If  $l \leq 3 + h_{2,n}$ , one then has from [4] that  $(M, T)$  and  $\Gamma^{l-3}(\mathbb{R}P^{n+3}, T_{2,n})$  are equivariantly cobordant, proving the result. By contradiction, suppose then  $l > 3 + h_{2,n}$ . Again from [4],

$$((n+1)\lambda_2 \oplus (l-3)R) \cup (3\lambda_n \oplus (l-3)R)$$

is the fixed data of an involution  $(W, S)$ , and by removing sections if necessary we can suppose, with no loss, that  $\dim(W) = n + h_{2,n} + 4$  [4, Theorem 26.4]. Let  $(N, T')$  be an involution cobordant to  $\Gamma^{h_{2,n}}(\mathbb{R}P^{n+3}, T_{2,n})$  and with fixed data

$$((n+1)\lambda_2 \oplus h_{2,n}R) \cup (3\lambda_n \oplus h_{2,n}R).$$

One knows that  $N$  is not a boundary. Then  $\Gamma(N, T') \cup (W, S)$  is cobordant to an involution with fixed data  $R \rightarrow N$ , and from [4]  $R \rightarrow N$  then is a boundary, which is impossible.

Now suppose  $n = 4$ . The case  $W(\eta) = (1 + \alpha)^5$  and  $W(\xi) = (1 + \beta)^3$  is included in the above approach, hence suppose  $W(\eta) = 1 + \alpha$  and  $W(\xi) = 1 + \beta$ . Since  $h_{0,2} = 2$ , the involution  $\Gamma^2(\mathbb{R}P^3, T_{0,2})$  is cobordant to an involution with fixed data

$$(5R \rightarrow \{\text{point}\}) \cup (\lambda_2 \oplus 2R \rightarrow \mathbb{R}P^2).$$

Then the involution  $\Gamma^2(\mathbb{R}P^3, T_{0,2}) \cup (\mathbb{R}P^5, T_{0,4})$  is cobordant to an involution  $(W^5, T)$  with fixed data  $(\lambda_2 \oplus 2R \rightarrow \mathbb{R}P^2) \cup (\lambda_4 \rightarrow \mathbb{R}P^4)$ , and the total Stiefel–Whitney classes are  $W(\lambda_2 \oplus 2R) = 1 + \alpha$  and  $W(\lambda_4) = 1 + \beta$ . Because  $h_{0,2} = 2$ , the underlying manifold of  $\Gamma^2(\mathbb{R}P^3, T_{0,2})$  does not bound; since  $\mathbb{R}P^5$  bounds,  $W^5$  does not bound. By contradiction, suppose  $l \geq 2$ . Using the hypothesis, [4] and removing sections if necessary, we can suppose with no loss that  $(M, T)$  has fixed data

$$(\lambda_2 \oplus 3R \rightarrow \mathbb{R}P^2) \cup (\lambda_4 \oplus R \rightarrow \mathbb{R}P^4).$$

Using the same above argument for  $\Gamma(W^5, T) \cup (M, T)$ , we conclude  $R \rightarrow W$  is a boundary, which is false. Then  $l = 1$  and  $(M, T)$  and  $(W^5, T)$  (and hence the union  $\Gamma^2(\mathbb{R}P^3, T_{0,2}) \cup (\mathbb{R}P^5, T_{0,4})$ ) have fixed data with same characteristic numbers.

In order to prove Lemma 3, we will intensively use the following basic fact from [4]: the projective space bundles  $\mathbb{R}P(\eta)$  and  $\mathbb{R}P(\xi)$  with the standard line bundles  $\lambda \rightarrow \mathbb{R}P(\eta)$  and  $\nu \rightarrow \mathbb{R}P(\xi)$  are cobordant as elements of the bordism group  $\mathcal{N}_{k+1}(BO(1))$ . Then any class of dimension  $k + 1$ , given by a product of the classes  $w_i(\mathbb{R}P(\eta))$  and  $w_1(\lambda)$ , evaluated on the fundamental homology class  $[\mathbb{R}P(\eta)]$ , gives the same characteristic number as the one obtained by the corresponding product of the classes  $w_i(\mathbb{R}P(\xi))$  and  $w_1(\nu)$ , evaluated on  $[\mathbb{R}P(\xi)]$ . To evaluate characteristic numbers, the following formula of Conner will be useful [2, Lemma 3.1]: if  $\pi: \mu \rightarrow N$  is any  $r$ -dimensional vector bundle,  $c$  is the first Stiefel–Whitney class of the standard line bundle over  $\mathbb{R}P(\mu)$ ,  $\bar{W}(\mu) = 1 + \bar{w}_1(\mu) + \bar{w}_2(\mu) + \dots$  is the dual Stiefel–Whitney class defined by  $W(\mu)\bar{W}(\mu) = 1$  and  $\alpha \in H^*(N, \mathbb{Z}_2)$ , then

$$(1) \quad c^j \pi^*(\alpha)[\mathbb{R}P(\mu)] = \bar{w}_{j-r+1}(\mu)\alpha[N] \quad \text{when } j \geq r - 1.$$

In this context, our numerical arguments will always be considered modulo 2. Write  $W(\lambda) = 1 + c$  and  $W(\nu) = 1 + d$  for the Stiefel–Whitney classes of  $\lambda$  and  $\nu$ . The structure of the Grothendieck ring of orthogonal bundles over real projective spaces says that  $W(\eta) = (1 + \alpha)^p$  and  $W(\xi) = (1 + \beta)^q$  for some  $p, q \geq 0$ . From [4, 23.3], one then has

$$W(\mathbb{R}P(\eta)) = (1 + \alpha)^3 \left( \sum_{i=0}^2 (1 + c)^{k-i} \binom{p}{i} \alpha^i \right)$$

and 
$$W(\mathbb{R}P(\xi)) = (1 + \beta)^{n+1} \left( \sum_{i=0}^l (1 + d)^{l-i} \binom{q}{i} \beta^i \right),$$

where here we are suppressing bundle maps.

**Fact 1** The numbers  $p$  and  $q$  are odd; in particular,  $w_1(\eta) = \alpha$  and  $w_1(\xi) = \beta$ .

**Proof** One has

$$w_1(\mathbb{R}P(\eta)) = \binom{k}{1}c + \alpha + \binom{p}{1}\alpha \quad \text{and} \quad w_1(\mathbb{R}P(\xi)) = \binom{l}{1}d + \beta + \binom{q}{1}\beta.$$

Since  $k + 2 = l + n$  and  $n$  is even,  $\binom{k}{1} = \binom{l}{1}$ , and thus

$$w_1(\mathbb{R}P(\eta)) + \binom{p}{1}c = \left(\binom{p}{1} + 1\right)\alpha \quad \text{and} \quad w_1(\mathbb{R}P(\xi)) + \binom{l}{1}d = \left(\binom{q}{1} + 1\right)\beta$$

are corresponding characteristic classes. Because  $n > 2$ , it follows that

$$\begin{aligned} 0 &= \left(\binom{p}{1} + 1\right)\alpha^n c^{l-1} [\mathbb{R}P(\eta)] = \left(\binom{q}{1} + 1\right)\beta^n d^{l-1} [\mathbb{R}P(\xi)] \\ &= \left(\binom{q}{1} + 1\right)\beta^n [\mathbb{R}P^n] = \binom{q}{1} + 1, \end{aligned}$$

which gives that  $q$  is odd. Also

$$\binom{p}{1} + 1 = \left(\binom{p}{1} + 1\right)\alpha^2 c^{k-1} [\mathbb{R}P(\eta)] = \left(\binom{q}{1} + 1\right)\beta^2 d^{k-1} [\mathbb{R}P(\xi)] = 0,$$

and  $p$  is odd. □

**Fact 2** If  $l = 1$ , then  $n = 4$ ,  $W(\eta) = 1 + \alpha$  and  $W(\xi) = 1 + \beta$ .

**Proof** Since  $l = 1$  and  $w_1(\xi) = \beta$ , we have  $W(\xi) = 1 + \beta$ . Then the involution  $(M, T) \cup (\mathbb{R}P^{n+1}, T_{0,n})$  is cobordant to an involution with fixed data

$$(\eta \rightarrow \mathbb{R}P^2) \cup ((n + 1)R \rightarrow \{\text{point}\}).$$

From [16] and the fact that  $h_{0,2} = 2$ , we have  $W(\eta) = 1 + \alpha$  and  $n = 4$ . □

Fact 2 reduces Lemma 3 to the following assertion: if  $l > 1$ , then  $W(\eta) = (1 + \alpha)^{n+1}$  and  $W(\xi) = (1 + \beta)^3$ ; so we assume throughout the remainder of this section that  $l > 1$ . Note that  $(1 + \alpha)^{n+1} = (1 + \alpha)^3$  if  $\binom{n}{2} = 1$  and  $(1 + \alpha)^{n+1} = 1 + \alpha$  if  $\binom{n}{2} = 0$ . Denote by  $r$  the greatest power of 2 that appears in the 2-adic expansion of  $n$ , that is,  $4 \leq 2^r \leq n < 2^{r+1}$ . We can assume  $q < 2^{r+1}$  and  $p < 4$ . Then Fact 3 and Fact 4 show that  $W(\eta) = (1 + \alpha)^{n+1}$ :

**Fact 3** If  $\binom{n}{2} = 1$ , then  $p = 3$ .

**Fact 4** If  $\binom{n}{2} = 0$ , then  $p = 1$ .

Set  $p' = 4 - p$ ,  $q' = 2^{r+1} - q$ . Then the dual Stiefel–Whitney classes of  $\eta$  and  $\xi$  are given by  $\bar{W}(\eta) = (1 + \alpha)^{p'}$ ,  $\bar{W}(\xi) = (1 + \beta)^{q'}$ . Since  $p$  and  $q$  are odd,  $p'$  and  $q'$  are odd; further,  $\binom{p}{2} + \binom{p'}{2} = 1$  and  $\binom{q}{2^u} + \binom{q'}{2^u} = 1$  for each  $1 \leq u \leq r$ .

**Proof of Fact 3** We will use several times the fact that a binomial coefficient  $\binom{a}{b}$  is nonzero modulo 2 if and only if the 2-adic expansion of  $b$  is a subset of the 2-adic expansion of  $a$ . We have  $n = 4j + 2$ , with  $j \geq 1$ , and want to show that  $p = 3$ ; since  $p < 4$  is odd, it suffices to show that  $\binom{p}{2} = 1$ , or equivalently that  $\binom{p'}{2} = 0$ . Suppose by contradiction that  $\binom{p'}{2} = 1$ . By Conner's formula (1),

$$c^{k+1}[\mathbb{R}P(\eta)] = \binom{p'}{2} \alpha^2 [\mathbb{R}P^2] = \binom{p'}{2} = d^{k+1}[\mathbb{R}P(\xi)] = \binom{q'}{4j+2}.$$

Then  $\binom{q'}{4j+2} = 1$  and consequently  $\binom{q'}{2} = 1$ . We formally introduce the class (with  $l - 1 \geq 1$ )

$$\widetilde{W}(\mathbb{R}P(\ )) = \frac{W(\mathbb{R}P(\ ))}{(1 + c)^{l-1}}.$$

Since  $k = l + 4j$  and  $p$  and  $q$  are odd, on  $\mathbb{R}P^2$  this class is

$$\widetilde{W}(\mathbb{R}P(\eta)) = (1 + \alpha)^3 (1 + c^4)^j (1 + c + \alpha + (1 + c)^{-1} \binom{p}{2} \alpha^2),$$

and on  $\mathbb{R}P^n$  it is

$$\widetilde{W}(\mathbb{R}P(\xi)) = (1 + \beta)^{4j+3} (1 + d + \beta + (1 + d)^{-1} \binom{q}{2} \beta^2 + (1 + d)^{-2} \binom{q}{3} \beta^3 + \dots).$$

Then 
$$\widetilde{w}_3(\mathbb{R}P(\eta)) = \alpha^2 c + \binom{p}{2} \alpha^2 c = \binom{p'}{2} \alpha^2 c = \alpha^2 c,$$

and since  $\binom{q}{2} + \binom{q'}{3} = 0$  because  $q$  is odd,  $\widetilde{w}_3(\mathbb{R}P(\xi)) = \binom{q'}{2} \beta^2 d = \beta^2 d$ . Now we observe that, if  $a$  and  $b$  are one-dimensional cohomology classes, then by the Cartan formula one has  $\text{Sq}^{2^u}(a^{2^u} b) = a^{2^{u+1}} b$ , where  $\text{Sq}$  is the Steenrod operation and  $u \geq 1$ .

Also one has, by the Wu and Cartan formulae, that  $\text{Sq}^i$  evaluated on a product of characteristic classes gives a polynomial in the characteristic classes. Then

$$\text{Sq}^{2^r-1}(\dots(\text{Sq}^4(\text{Sq}^2(\alpha^2 c)))\dots) = \alpha^{2^r} c$$

and 
$$\text{Sq}^{2^r-1}(\dots(\text{Sq}^4(\text{Sq}^2(\beta^2 d)))\dots) = \beta^{2^r} d$$

are corresponding classes on  $\mathbb{R}P^2$  and  $\mathbb{R}P^n$ . Using Conner's formula (1) and the fact that  $2^r \geq 4$ , one then has

$$0 = (\alpha^{2^r} c)c^{4j+1-2^r+l-1}[\mathbb{R}P(\eta)] = (\beta^{2^r} d)d^{4j+1-2^r+l-1}[\mathbb{R}P(\xi)] = \binom{q'}{4j+2-2^r}.$$

Since  $\binom{q'}{4j+2} = 1$  and  $2^r$  belongs to the 2-adic expansion of  $4j+2$ , also  $\binom{q'}{4j+2-2^r} = 1$ , which is impossible. Hence Fact 3 is proved.  $\square$

**Proof of Fact 4** We consider  $n = 4j$  with  $j \geq 1$ ; in this case, to show that  $p = 1$ , it suffices to show that  $\binom{p'}{2} = 1$ , and again by contradiction we suppose  $\binom{p'}{2} = 0$ . Then  $\binom{p'}{2} = 1$  and  $k = l + 4j - 2$  gives

$$\widetilde{W}(\mathbb{R}P(\eta)) = (1 + \alpha)^3((1 + c)^{4j-1} + (1 + c)^{4j-2}\alpha + (1 + c)^{4j-3}\alpha^2)$$

and  $\widetilde{w}_2(\mathbb{R}P(\eta)) = c^2 + \alpha^2 + c\alpha$ . Also

$$\widetilde{W}(\mathbb{R}P(\xi)) = (1 + \beta)^{4j+1}(1 + d + \beta + (1 + d)^{-1}\binom{q}{2}\beta^2 + (1 + d)^{-2}\binom{q}{3}\beta^3 + \dots)$$

and  $\widetilde{w}_2(\mathbb{R}P(\xi)) = \binom{q}{2}\beta^2 + \beta d + \beta^2$ . Let  $2^t$  be the lesser power of 2 of the 2-adic expansion of  $n = 4j$  ( $2^t \geq 4$ ). For  $t \leq x \leq r$  and with the same preceding tools, we then get

$$\begin{aligned} & \text{Sq}^{2^x-1}(\dots(\text{Sq}^4(\text{Sq}^2(\widetilde{w}_2(\mathbb{R}P(\eta))c)))\dots)c^{4j+l-2^x-2}[\mathbb{R}P(\eta)] \\ &= (c^{2^x}c + \alpha^{2^x}c + c^{2^x}\alpha)c^{4j+l-2^x-2}[\mathbb{R}P(\eta)] \\ &= \binom{p'}{2} + 0 + \binom{p'}{1} \\ &= 1 \\ &= \text{Sq}^{2^x-1}(\dots(\text{Sq}^4(\text{Sq}^2(\widetilde{w}_2(\mathbb{R}P(\xi))d)))\dots)d^{4j+l-2^x-2}[\mathbb{R}P(\xi)] \\ &= (\binom{q}{2}\beta^{2^x}d + \beta d^{2^x} + \beta^{2^x}d)d^{4j+l-2^x-2}[\mathbb{R}P(\xi)] \\ &= \binom{q}{2}\binom{q'}{4j-2^x} + \binom{q'}{4j-1} + \binom{q'}{4j-2^x} = \binom{q'}{2}\binom{q'}{4j-2^x} + \binom{q'}{4j-1}, \\ & 0 = \binom{p'}{2} = c^{k+1}[\mathbb{R}P(\eta)] = d^{k+1}[\mathbb{R}P(\xi)] = \binom{q'}{4j} \end{aligned}$$

$$\begin{aligned}
\text{and } \tilde{w}_2(\mathbb{R}P(\eta))c^{4j+l-3}[\mathbb{R}P(\eta)] &= \binom{p'}{2} + 1 + \binom{p'}{1} = 0 \\
&= \tilde{w}_2(\mathbb{R}P(\xi))d^{4j+l-3}[\mathbb{R}P(\xi)] \\
&= \binom{q}{2}\binom{q'}{4j-2} + \binom{q'}{4j-1} + \binom{q'}{4j-2} \\
&= \binom{q'}{2}\binom{q'}{4j-2} + \binom{q'}{4j-1}.
\end{aligned}$$

That is, we get the equations:

$$\begin{aligned}
(2) \quad & 0 = \binom{q'}{4j} \\
(3) \quad & 0 = \binom{q'}{2}\binom{q'}{4j-2} + \binom{q'}{4j-1} \\
(4) \quad & 1 = \binom{q'}{2}\binom{q'}{4j-2x} + \binom{q'}{4j-1}
\end{aligned}$$

By using equations (3) and (4), we conclude that  $\binom{q'}{2} = 1$  and  $\binom{q'}{4j-2x} \neq \binom{q'}{4j-2}$ . Suppose  $t < r$ . If  $\binom{q'}{4j-2r} = 1$ , equation (2) and the fact that  $2^r$  belongs to the 2-adic expansion of  $4j$  imply that  $2^r$  is the only power of 2 of the 2-adic expansion of  $4j$  that does not belong to the 2-adic expansion of  $q'$ . Hence  $\binom{q'}{4j-2t} = 0$ , which is a contradiction. Then  $\binom{q'}{4j-2r} = \binom{q'}{4j-2t} = 0$ . In this case, equation (2) and  $\binom{q'}{4j-2} = 1$  give that  $2^t$  is the only power of 2 of the 2-adic expansion of  $4j$  that does not belong to the 2-adic expansion of  $q'$ , giving the contradiction  $\binom{q'}{4j-2t} = 1$ . Now suppose  $t = r$ , that is,  $n = 4j = 2^r$ . One has

$$\begin{aligned}
(\tilde{w}_2(\mathbb{R}P(\eta)))^2 c^{2^r+l-5}[\mathbb{R}P(\eta)] &= \binom{p'}{2} + 0 + 1 \\
&= 1 = (\tilde{w}_2(\mathbb{R}P(\xi)))^2 d^{2^r+l-5}[\mathbb{R}P(\xi)] \\
&= \binom{q}{2}\binom{q'}{2^r-4} + \binom{q'}{2^r-2} + \binom{q'}{2^r-4} \\
&= \binom{q'}{2}\binom{q'}{2^r-4} + \binom{q'}{2^r-2} = \binom{q'}{2^r-4} + \binom{q'}{2^r-2}.
\end{aligned}$$

Since  $\binom{q'}{2} = 1$ , we have  $\binom{q'}{2^r-4} = \binom{q'}{2^r-2}$ , which gives a contradiction. Thus Fact 4 is proved.  $\square$

Now we prove that  $q = 3$ . To do this, first we prove:

**Fact 5**  $\binom{q}{2} = 1$ ; in particular,  $q \geq 3$ .

**Proof** As before, first consider  $n = 4j + 2$ , with  $j \geq 1$ . In this case, we know that  $0 = \binom{p'}{2} = \binom{q'}{4j+2}$ ,  $\tilde{w}_2(\mathbb{R}P(\eta)) = \binom{p}{2}\alpha^2 + \alpha c = \alpha^2 + \alpha c$  and  $\tilde{w}_2(\mathbb{R}P(\xi)) = \binom{q}{2}\beta^2 + \beta d$ . Then

$$\begin{aligned}
(\tilde{w}_2(\mathbb{R}P(\eta)))^2 c^{4j+l-3}[\mathbb{R}P(\eta)] &= 1 \\
&= (\tilde{w}_2(\mathbb{R}P(\xi)))^2 d^{4j+l-3}[\mathbb{R}P(\xi)] = \binom{q}{2}\binom{q'}{4j-2} + \binom{q'}{4j}.
\end{aligned}$$

Since the sum  $\binom{q}{2} + \binom{q'}{2}$  equals 1 and 2 belongs to the 2-adic expansion of  $4j - 2$ , one has that  $\binom{q}{2} \binom{q'}{4j-2} = 0$ , and thus  $\binom{q'}{4j} = 1$ . Now  $\binom{q'}{4j+2} = 0$  and  $\binom{q'}{4j} = 1$  imply that  $\binom{q'}{2} = 0$ , and thus  $\binom{q}{2} = 1$ . Since  $q$  is odd, this means that  $q \geq 3$ .

Now suppose  $n = 4j$ , with  $j \geq 1$ . One then has  $\binom{p'}{2} = 1$ ,  $\tilde{w}_3(\mathbb{R}P(\eta)) = c^3 + \binom{p'}{2} \alpha^2 c = c^3 + \alpha^2 c$  and  $\tilde{w}_3(\mathbb{R}P(\xi)) = \binom{q}{2} \beta^2 d$ . Then

$$\begin{aligned} \text{Sq}^{2^{r-1}}(\dots(\text{Sq}^4(\text{Sq}^2(\tilde{w}_3(\mathbb{R}P(\eta))))\dots)c^{4j+l-2r-2}[\mathbb{R}P(\eta)]) \\ &= (c^{2^r} c + \alpha^{2^r} c) c^{4j+l-2r-2}[\mathbb{R}P(\eta)] \\ &= \binom{p'}{2} = 1 \\ &= \text{Sq}^{2^{r-1}}(\dots(\text{Sq}^4(\text{Sq}^2(\binom{q}{2} \beta^2 d)))\dots)d^{4j+l-2r-2}[\mathbb{R}P(\xi)] \\ &= (\binom{q}{2} \beta^2 d) d^{4j+l-2r-2}[\mathbb{R}P(\xi)] = \binom{q}{2} \binom{q'}{4j-2r}. \end{aligned}$$

Thus  $\binom{q}{2} = 1$ , and Fact 5 is proved.  $\square$

To end our task, we will show that  $q \leq 3$ . The strategy will consist in finding nonzero characteristic numbers coming from characteristic classes involving  $\alpha^{q-1}$ . To do this, we need the following:

**Fact 6**  $n + l - 1 > 2(q - 1)$ .

**Proof** First suppose  $n = 4j + 2$ ,  $j \geq 1$ . From the proof of Fact 5,  $\binom{q'}{4j} = 1$ , and thus  $\binom{q'}{2r} = 1$  and  $\binom{q}{2r} = 0$ . Since  $q < 2^{r+1}$ ,  $q < 2^r < 4j + 2$ . In particular,  $w_q(\xi) = \alpha^q \neq 0$  and  $q \leq l$ . Then  $n + l - 1 = 4j + 2 + l - 1 > 2q - 1 > 2(q - 1)$ . Now suppose  $n = 4j$ ,  $j \geq 1$ . In this case,  $\binom{p'}{2} = 1 = \binom{q'}{4j}$ , so the argument is the same.  $\square$

Fact 6 says that we can consider characteristic numbers coming from classes involving  $\tilde{w}_2^{q-1}$ ; in this direction, first consider  $n = 4j + 2$ ,  $j \geq 1$ . In this case,

$$\tilde{w}_2(\mathbb{R}P(\eta)) = \binom{p}{2} \alpha^2 + \alpha c = \alpha(\alpha + c) \quad \text{and} \quad \tilde{w}_2(\mathbb{R}P(\xi)) = \binom{q}{2} \beta^2 + \beta d = \beta(\beta + d).$$

Thus

$$(\alpha^{q-1}(\alpha + c)^{q-1} c^{4j+l-2q+3})[\mathbb{R}P(\eta)] = (\beta^{q-1}(\beta + d)^{q-1} d^{4j+l-2q+3})[\mathbb{R}P(\xi)].$$

The last term is the coefficient of  $\beta^{4j+2}$  in  $\beta^{q-1}(1 + \beta)^{q-1}(1 + \beta)^{q'}$ , by Conner's formula (1). If  $n = 4j$ ,  $j \geq 1$ , similarly one has

$$\begin{aligned} \tilde{w}_2(\mathbb{R}P(\eta)) + c^2 &= (c^2 + \binom{p}{2} \alpha^2 + \alpha c) + c^2 = \alpha c, \\ \tilde{w}_2(\mathbb{R}P(\xi)) + d^2 &= \binom{q'}{2} \beta^2 + \beta d + d^2 = (\beta + d)d, \\ ((\alpha^{q-1} c^{q-1}) c^{4j+l-2q+1})[\mathbb{R}P(\eta)] &= ((\beta + d)d)^{q-1} d^{4j+l-2q+1}[\mathbb{R}P(\xi)], \end{aligned}$$

and the last term is the coefficient of  $\beta^{4j}$  in  $(1 + \beta)^{q-1}(1 + \beta)^{q'}$ . These numbers have value 1, since  $(1 + \beta)^{q-1}(1 + \beta)^{q'} = (1 + \beta)^{-1}$ , which means that  $\alpha^{q-1} \neq 0$  and  $q - 1 \leq 2$ , thus ending the proof of Lemma 3.

### 3 Calculation of $h_{m,n}$

Denote by  $\mathcal{W}_r$  the underlying manifold of  $\Gamma^r(\mathbb{R}P^{m+n+1}, T_{m,n})$  and by  $\mathcal{P}_r$  the total space of the iterated fibration

$$\mathbb{R}P((m+1)\mu_r \oplus (n+1)R) \rightarrow \mathbb{R}P(\lambda_1 \oplus (r-1)R) \rightarrow \mathbb{R}P^1,$$

where  $\mu_r$  is the standard line bundle over  $\mathbb{R}P(\lambda_1 \oplus (r-1)R)$ .

**Lemma 4**  $\mathcal{W}_r$  is cobordant to  $\mathcal{P}_r$ .

**Proof** If  $(W, T)$  is a free involution and  $\lambda \rightarrow W/T$  is the usual line bundle, the sphere bundle  $S(\lambda \oplus R)$  with the antipodal involution in the fibers can be identified to the free involution

$$\left( \frac{W \times S^1}{T \times c}, \tau \right),$$

where  $c$  is complex conjugation and  $\tau$  is induced by  $\text{Id} \times -\text{Id}$ . Starting with  $(S^1, -\text{Id})$  and by iteratively applying this fact, we can see that  $\mathcal{W}_r$  is diffeomorphic to the total space of the iterated fibration

$$\mathbb{R}P((m+1)\xi_r \oplus (n+1)R) \rightarrow \mathbb{R}P(\xi_{r-1} \oplus R) \rightarrow \dots \rightarrow \mathbb{R}P(\xi_2 \oplus R) \rightarrow \mathbb{R}P(\xi_1 \oplus R) \rightarrow \mathbb{R}P^1,$$

where  $\xi_1 = \lambda_1$  and  $\xi_i$  is the standard line bundle over  $\mathbb{R}P(\xi_{i-1} \oplus R)$ , for each  $i > 1$ . From [4], one knows that  $\mathcal{N}_*(BO(1))$  is a free  $\mathcal{N}_*$ -module, where  $\mathcal{N}_*$  is the unoriented cobordism ring, with one generator  $X_j$  in each dimension  $j \geq 0$ ; these generators are characterized by the fact that  $c^j[V^j] = 1$ , where  $\lambda \rightarrow V^j$  is a representative of  $X_j$  and  $c$  is the first Whitney class of  $\lambda$ . Further, it was shown by Conner in [3, Theorem 24.5] that there is a unique basis  $\{X_j\}_{j=0}^\infty$  for  $\mathcal{N}_*(BO(1))$  which satisfies two conditions:

- (i)  $\Delta(X_j) = X_{j-1}$ ,  $j \geq 1$ , where  $\Delta: \mathcal{N}_j(BO(1)) \rightarrow \mathcal{N}_{j-1}(BO(1))$  is the Smith homomorphism.
- (ii) If  $\lambda \rightarrow V^j$  is a representative of  $X_j$  for  $j \geq 1$ , then  $V^j$  bounds.

Theorem 24.5 of [3] also showed that  $X_1 = [\xi_1 \rightarrow \mathbb{R}P^1]$  and  $X_j = [\xi_j \rightarrow \mathbb{R}P(\xi_{j-1} \oplus R)]$  for  $j \geq 2$ . For  $j \geq 1$ , set  $Y_j = [\mu_j \rightarrow \mathbb{R}P(\lambda_1 \oplus (j-1)R)]$ . One has

$$c^j[\mathbb{R}P(\lambda_1 \oplus (j-1)R)] = \bar{w}_1(\lambda_1)[S^1] = 1,$$

$$Y_1 = X_1$$

and  $\Delta([\mu_j \rightarrow \mathbb{R}P(\lambda_1 \oplus (j-1)R)]) = [\mu_{j-1} \rightarrow \mathbb{R}P(\lambda_1 \oplus (j-2)R)]$  for  $j \geq 2$ .

Further, every projective space bundle over  $S^1$  bounds [5, Lemma 2.2]. By the uniqueness,  $Y_j = X_j$  for  $j \geq 1$ , and the result follows.  $\square$

With the Lemma 4 in hand, Theorem 2 can now be rephrased:

**Theorem 2'** For  $m, n$  even,  $0 \leq m < n$ , write  $n - m = 2^p q$  with  $p \geq 1$  and  $q \geq 1$  odd.

- (a) If  $p = 1$ ,  $\mathcal{P}_1$  bounds and  $\mathcal{P}_2$  does not bound.
- (b) If  $p > 1$ ,  $\mathcal{P}_r$  bounds for each  $1 \leq r \leq 2^p - 2$  and  $\mathcal{P}_{2^p-1}$  does not bound.

Denote by  $\alpha \in H^1(\mathbb{R}P^1, Z_2)$  the generator and by  $\theta_r \rightarrow \mathcal{P}_r$  the standard line bundle; set  $W(\mu_r) = 1 + c$  and  $W(\theta_r) = 1 + d$ . The following lemma, which follows from Conner's formula (1), will be useful in our computations:

- Lemma 5** (i) For  $f + g + h = m + n + 1 + r$ ,  $c^f (c + d)^g d^h [\mathcal{P}_r]$  is the coefficient of  $c^r$  in  $(c^f (1 + c)^g) / ((1 + c)^{m+1})$ .
- (ii) For  $f + g + h = m + n + r$ ,  $\alpha c^f (c + d)^g d^h [\mathcal{P}_r]$  is the coefficient of  $c^r$  in  $(c^{f+1} (1 + c)^g) / ((1 + c)^{m+1})$ .

If  $M$  is a closed manifold and  $(1 + t_1)(1 + t_2) \dots (1 + t_l)$  is the factored form of  $W(M)$ , one has the  $s$ -class  $s_j$  given by the polynomial in the classes of  $M$  corresponding to the symmetric function  $t_1^j + t_2^j + \dots + t_l^j$ . Since

$$W(\mathcal{P}_r) = (1 + c + \alpha)(1 + c)^{r-1}(1 + c + d)^{m+1}(1 + d)^{n+1},$$

$c^i = 0$  if  $i > r$  and  $\alpha^i = 0$  if  $i > 1$ , the  $s$ -class  $s_{m+n+1+r}$  of  $\mathcal{P}_r$  then is

$$\begin{aligned} s_{m+n+1+r} &= (c + \alpha)^{m+n+1+r} + (r-1)c^{m+n+1+r} \\ &\quad + (m+1)(c + d)^{m+n+1+r} + (n+1)d^{m+n+1+r} \\ &= (c + d)^{m+n+1+r} + d^{m+n+1+r}. \end{aligned}$$

Using part (i) of Lemma 5 and the fact that

$$\frac{1}{(1 + c)^{m+1}} = 1 + \sum_{i=1}^r \binom{m+i}{i} c^i$$

in  $H^*(\mathcal{P}_r, Z_2)$ , one then has

$$\begin{aligned} s_{m+n+1+r}[\mathcal{P}_r] &= \text{coefficient of } c^r \text{ in } (1+c)^{n+r} + \text{coefficient of } c^r \text{ in } \frac{1}{(1+c)^{m+1}} \\ &= \binom{n+r}{r} + \binom{m+r}{r}. \end{aligned}$$

Because  $n = 2^p q + m$  and  $q$  is odd, one then gets

$$s_{m+n+1+2^p}[\mathcal{P}_{2^p}] = \binom{n+2^p}{2^p} + \binom{m+2^p}{2^p} = 1.$$

It follows that  $\mathcal{P}_{2^p}$  does not bound. Because  $\mathcal{P}_1$  is a projective space bundle over  $S^1$  and hence a boundary, this in particular proves part (a) of Theorem 2'. So we can assume from now that  $p > 1$  and  $r < 2^p$ . Using again  $n = 2^p q + m$ , we rewrite  $W(\mathcal{P}_r)$  as

$$W(\mathcal{P}_r) = (1+c+\alpha)(1+c)^{r-1}(1+c+d(c+d))^{m+1}(1+d^{2^p})^q.$$

Then a general characteristic number of  $\mathcal{P}_r$  is a sum of terms of the form

$$\alpha^e c^f (d(c+d))^g d^{2^p h} [\mathcal{P}_r],$$

where  $e + f + 2g + 2^p h = m + n + 1 + r$  and either  $e = 0$  or  $e = 1$ . Since by Lemma 5,

$$\alpha^e c^f (d(c+d))^g d^{2^p h} [\mathcal{P}_r] = c^{f+1} (d(c+d))^g d^{2^p h} [\mathcal{P}_r],$$

we can assume  $e = 0$ . Thus, to prove the first statement of part (b) of Theorem 2', it suffices to show that  $c^f (d(c+d))^g d^{2^p h} [\mathcal{P}_r] = 0$  when  $f + 2g + 2^p h = m + n + 1 + r$  and  $r < 2^p - 1$ . Since  $c^f = 0$  if  $f > r$ , we assume  $f \leq r$  and thus  $0 \leq r - f < 2^p - 1$ . Take  $s > p$  with  $2^s > m + 1$ ; in particular,  $2^s > 2^p > r$  and  $1/((1+c)^{m+1}) = (1+c)^{2^s - m - 1}$ . Then

$$\begin{aligned} c^f (d(c+d))^g d^{2^p h} [\mathcal{P}_r] &= \text{coefficient of } c^r \text{ in } c^f (1+c)^g / (1+c)^{m+1} \\ &= \text{coefficient of } c^r \text{ in } c^f (1+c)^g (1+c)^{2^s - m - 1} \\ &= \binom{2^s + g - m - 1}{r - f} \\ &= \binom{2^{p-1}(2^{s-p+1} + q - h) + (r - f + 1)/2 - 1}{r - f}. \end{aligned}$$

Write  $r - f + 1 = 2^t a$ , where  $a$  is odd. Since  $r - f + 1 = 2g + 2^p h - m - n$  is even and  $r - f + 1 < 2^p$ , one has  $1 \leq t \leq p - 1$ . Then  $2^{t-1}$  belongs to the 2-adic expansion of  $r - f$  and does not belong to the 2-adic expansion of

$$2^{p-1}(2^{s-p+1} + q - h) + (r - f + 1)/2 - 1,$$

which means, as required, that the above number is zero.

Finally, we must to show that  $\mathcal{P}_{2^p-1}$  does not bound. One has

$$w_2(\mathcal{P}_{2^p-1}) = \alpha c + \binom{m+1}{2} c^2 + d(c+d).$$

We have seen above that  $c^f (d(c+d))^g d^{2^p h} [\mathcal{P}_r] = 0$  for  $f+2g+2^p h = m+n+1+r$  and  $0 \leq r-f < 2^p-1$ ; in particular, this is true for  $r = 2^p-1$  and  $f > 0$ . In this way,

$$\begin{aligned} w_2(\mathcal{P}_{2^p-1})^{\frac{m+n+2^p}{2}} [\mathcal{P}_{2^p-1}] &= (d(c+d))^{\frac{m+n+2^p}{2}} [\mathcal{P}_{2^p-1}] \\ &= \text{coefficient of } c^{2^p-1} \text{ in } ((1+c)^{\frac{m+n+2^p}{2}}) / (1+c)^{m+1} \\ &= \text{coefficient of } c^{2^p-1} \text{ in } (1+c)^{\frac{n-m}{2}+2^{p-1}-1} \\ &= \binom{2^{p-1}q+2^{p-1}-1}{2^{p-1}} = 1, \end{aligned}$$

and  $\mathcal{P}_{2^p-1}$  does not bound.

#### 4 $Z_2^k$ -actions fixing $\mathbb{R}P^2 \cup \mathbb{R}P^{\text{even}}$

Let  $F^n$  be a connected, smooth and closed  $n$ -dimensional manifold satisfying the following property, which we call *property  $\mathcal{H}$* : if  $N^m$  is any smooth and closed  $m$ -dimensional manifold with  $m > n$  and  $T: N^m \rightarrow N^m$  is a smooth involution whose fixed point set is  $F^n$ , then  $m = 2n$ . From [8], this implies that  $(N^m, T)$  is cobordant to the *twist involution*  $(F^n \times F^n, t)$ , given by  $t(x, y) = (y, x)$ . This concept was introduced and studied in Pergher and Oliveira [14], inspired by Conner and Floyd [4, 27.6] (or Conner [3, 29.2]), where it was shown that  $\mathbb{R}P^{\text{even}}$  has this property.

In [13], we studied the equivariant cobordism classification of smooth actions  $(M; \Phi)$  of the group  $Z_2^k$  on closed and smooth manifolds  $M$  for which the fixed point set  $F$  of the action is the union  $F = K \cup L$ , where  $K$  and  $L$  are submanifolds of  $M$  with property  $\mathcal{H}$  and with  $\dim(K) < \dim(L)$ . We showed that, for this  $F$ , the  $Z_2^k$ -classification is completely determined by the corresponding  $Z_2$ -classification. Specifically, the equivariant cobordism classes of  $Z_2^k$ -actions fixing  $K \cup L$  can be represented by a special set of  $Z_2^k$ -actions which are explicitly obtained from involutions fixing  $K \cup L$ ,  $K$  and  $L$ . Together with the results of Section 2 and Section 3 and the case  $F = \mathbb{R}P^{\text{even}}$ , this gives a precise cobordism description of the  $Z_2^k$ -actions fixing  $\mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $n > 2$  is even; next we give this description.

Here,  $Z_2^k$  is the group generated by  $k$  commuting involutions  $T_1, T_2, \dots, T_k$ . The *fixed data* of a  $Z_2^k$ -action  $(M; \Phi)$ ,  $\Phi = (T_1, T_2, \dots, T_k)$ , is  $\eta = \bigoplus_{\rho} \varepsilon_{\rho} \rightarrow F$ , where  $F = \{x \in M / T_i(x) = x \text{ for all } 1 \leq i \leq k\}$  is the fixed point set of  $\Phi$  and  $\eta = \bigoplus_{\rho} \varepsilon_{\rho}$  is the normal bundle of  $F$  in  $M$ , decomposed into eigenbundles  $\varepsilon_{\rho}$  with  $\rho$  running

through the  $2^k - 1$  nontrivial irreducible representations of  $Z_2^k$ . A collection of  $Z_2^k$ -actions fixing  $F$  can be obtained from an involution fixing  $F$  through the following procedure: let  $(W, T)$  be any involution. For each  $r$  with  $1 \leq r \leq k$ , consider the  $Z_2^k$ -action  $\Gamma_r^k(W, T)$ , defined on the cartesian product  $W^{2^{r-1}} = W \times \dots \times W$  ( $2^{r-1}$  factors) and described in the following inductive way: first set  $\Gamma_1^1(W, T) = (W, T)$ . Taking  $k \geq 2$  and supposing by inductive hypothesis one has constructed  $\Gamma_{k-1}^{k-1}(W, T)$ , define

$$\Gamma_k^k(W, T) = (W^{2^{k-1}}; T_1, T_2, \dots, T_k),$$

$$\begin{aligned} \text{where } (W^{2^{k-1}}; T_1, T_2, \dots, T_{k-1}) &= (W^{2^{k-2}} \times W^{2^{k-2}}; T_1, T_2, \dots, T_{k-1}) \\ &= \Gamma_{k-1}^{k-1}(W, T) \times \Gamma_{k-1}^{k-1}(W, T), \end{aligned}$$

and  $T_k$  acts switching  $W^{2^{k-2}} \times W^{2^{k-2}}$ . This defines  $\Gamma_k^k(W, T)$  for any  $k \geq 1$ . Next, define

$$\Gamma_r^k(W, T) = (W^{2^{r-1}}; T_1, T_2, \dots, T_k)$$

$$\text{setting } (W^{2^{r-1}}; T_1, T_2, \dots, T_r) = \Gamma_r^r(W, T)$$

and letting  $T_{r+1}, \dots, T_k$  act trivially.

If  $(W, T)$  fixes  $F$  and if  $\eta \rightarrow F$  is the normal bundle of  $F$  in  $W$ , then  $\Gamma_r^k(W, T)$  fixes  $F$  and its fixed data consists of  $2^{r-1}$  copies of  $\eta$ ,  $2^{r-1} - 1$  copies of the tangent bundle of  $F$  and  $2^k - 2^r$  copies of the zero-dimensional bundle over  $F$ . In particular, for the twist involution  $(F \times F, t)$ , we have  $\Gamma_r^k(F \times F, t) = (F^{2^r}; T_1, T_2, \dots, T_k)$ , where  $(T_1, T_2, \dots, T_r)$  is the usual twist  $Z_2^r$ -action on  $F^{2^r}$  which interchanges factors and  $T_{r+1}, \dots, T_k$  act trivially, with the fixed data having in this case  $2^r - 1$  copies of the tangent bundle of  $F$  and  $2^k - 2^r$  zero bundles. In this special case, we allow  $r$  to be zero, setting  $\Gamma_0^k(F \times F, t) = (F; T_1, T_2, \dots, T_k)$ , where each  $T_i$  is the identity involution.

Now, from a given  $Z_2^k$ -action  $(M; \Phi)$ ,  $\Phi = (T_1, \dots, T_k)$ , we can obtain a collection of new  $Z_2^k$ -actions, described as follows: first, each automorphism  $\sigma: Z_2^k \rightarrow Z_2^k$  yields a new action given by  $(M; \sigma(T_1), \dots, \sigma(T_k))$ ; we denote this action by  $\sigma(M; \Phi)$ . The fixed data of  $\sigma(M; \Phi)$  is obtained from the fixed data of  $(M; \Phi)$  by a permutation of eigenbundles, obviously depending on  $\sigma$ . Next, it was shown in [12] that if  $(M; \Phi)$  has fixed data  $\bigoplus_{\rho} \varepsilon_{\rho} \rightarrow F$  and one of the eigenbundles  $\varepsilon_{\theta}$  is isomorphic to  $\varepsilon'_{\theta} \oplus R$ , then there is an action  $(N; \Psi)$  with fixed data  $\bigoplus_{\rho} \mu_{\rho} \rightarrow F$ , where  $\mu_{\rho} = \varepsilon_{\rho}$  if  $\rho \neq \theta$  and  $\mu_{\theta} = \varepsilon'_{\theta}$ . We say in this case that  $(N; \Psi)$  is obtained from  $(M; \Phi)$  by removing one section. Thus, the iterative process of removing sections may possibly enlarge the set  $\{\sigma(M; \Phi), \sigma \in \text{Aut}(Z_2^k)\}$ . Summarizing, from a given involution  $(W, T)$  that fixes

$F$ , we obtain a collection of  $Z_2^k$ -actions fixing  $F$  by applying the operations  $\sigma\Gamma_r^k$  on  $(W, T)$  and next by removing the (possible) sections from the resultant eigenbundles. The results of [13] say that when  $F = K \cup L$ , where  $K$  and  $L$  have property  $\mathcal{H}$  and  $\dim(K) < \dim(L)$ , then up to equivariant cobordism, all  $Z_2^k$ -actions fixing  $F$  are obtained, with the above procedure, from involutions fixing  $K \cup L$ ,  $K$  and  $L$ . Together with the  $Z_2$ -classification obtained in Section 2 and Section 3 and the case  $F = \mathbb{R}P^{\text{even}}$ , this gives the following  $Z_2^k$ -classification for  $F = \mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $n > 2$  is even (in our terminology, we agree that *the set obtained from  $(M; \Phi)$  by removing sections* includes  $(M; \Phi)$ ):

**Theorem 6** *Let  $(M; \Phi)$  be a  $Z_2^k$ -action fixing  $\mathbb{R}P^2 \cup \mathbb{R}P^n$ , where  $n > 2$  is even. Then  $(M; \Phi)$  is equivariantly cobordant to an action belonging to the set  $A \cup B$ , where the sets  $A$  and  $B$  are described below in terms of  $n$ .*

(i)  $n - 2 = 2^p q$ , with  $q$  odd and  $p > 1$ :

$A = \emptyset =$  the empty set;

$B =$  the set obtained from  $\{\sigma\Gamma_r^k\Gamma^{2^p-1}(\mathbb{R}P^{n+3}, T_{2,n}), \sigma \in \text{Aut}(Z_2^k), 1 \leq r \leq k\}$  by removing sections.

(ii)  $n - 2 = 2q$ , with  $q$  odd, and  $n$  is not a power of 2:

$A = \emptyset$ ;

$B =$  the set obtained from  $\{\sigma\Gamma_r^k\Gamma^2(\mathbb{R}P^{n+3}, T_{2,n}), \sigma \in \text{Aut}(Z_2^k), 1 \leq r \leq k\}$  by removing sections;

(iii)  $n = 2^t$  is a power of 2 with  $t \geq 3$ :

$A = \{\sigma\Gamma_r^k(\mathbb{R}P^2 \times \mathbb{R}P^2, \text{twist}) \cup \sigma'\Gamma_{r-t+1}^k(\mathbb{R}P^{2^t} \times \mathbb{R}P^{2^t}, \text{twist}),$   
 $\sigma, \sigma' \in \text{Aut}(Z_2^k), t - 1 \leq r \leq k\}$ ;

$B =$  the set obtained from  $\{\sigma\Gamma_r^k\Gamma^2(\mathbb{R}P^{2^t+3}, T_{2,2^t}), \sigma \in \text{Aut}(Z_2^k), 1 \leq r \leq k\}$  by removing sections (by dimensional reasons, in this case  $A = \emptyset$  if  $t - 1 > k$ );

(iv)  $n = 4$ : for  $(W^5, T) = \Gamma^2(\mathbb{R}P^3, T_{0,2}) \cup (\mathbb{R}P^5, T_{0,4})$ ,

$A = \{\sigma\Gamma_{r+1}^k(\mathbb{R}P^2 \times \mathbb{R}P^2, \text{twist}) \cup \sigma'\Gamma_r^k(\mathbb{R}P^4 \times \mathbb{R}P^4, \text{twist}),$   
 $\sigma, \sigma' \in \text{Aut}(Z_2^k), 0 \leq r \leq k - 1\}$   
 $\cup \{\sigma\Gamma_r^k(W^5, T), \sigma \in \text{Aut}(Z_2^k), 1 \leq r \leq k\}$ ;

$B =$  the set obtained from  $\{\sigma\Gamma_r^k\Gamma^2(\mathbb{R}P^7, T_{2,4}), \sigma \in \text{Aut}(Z_2^k), 1 \leq r \leq k\}$  by removing sections.
