Algebraic structure and integration maps in cocycle models for differential cohomology

MARKUS UPMEIER

We construct explicit multiplicative and additive structures as well as integration maps on differential extensions of rationally even cohomology theories in the Hopkins–Singer cocycle model. To this end, we consider also a pair-theory for which a long exact sequence is established.

55N20; 55S05

1 Introduction

Let $E$ be a multiplicative cohomology theory satisfying Milnor’s wedge axiom. Then one has the multiplicative Chern–Dold transformation [8]

(1) \[ \text{ch}: E^n(X, A) \to H^n(X, A; V) = \prod_{i \in \mathbb{Z}} H^i(X, A; V^{n-i}) \]

of cohomology theories for the graded coefficient vector space $V^* = \pi_* E \otimes \mathbb{R}$. We always assume $E$ to be rationally even, meaning $V^{2n+1} = 0$ for all $n \in \mathbb{Z}$.

Definition 1.1 A differential extension [4] of $E$ consists of a contravariant functor $\hat{E}$ from the category of manifolds to graded abelian groups along with natural linear transformations $I, R, a$ as in the following commutative diagram, which is required to have an exact upper horizontal row.

\[
\begin{array}{ccccccc}
E^{n-1}(M) & \xrightarrow{\text{ch}} & \Omega^{n-1}(M; V)/\text{im}(d) & \xrightarrow{a} & \hat{E}^n(M) & \xrightarrow{I} & E^n(M) & \xrightarrow{} & 0 \\
& & & & d & & R & & \\
& & & & \Omega^n_{cl}(M; V) & \xrightarrow{\text{ch}} & H^n(M; V)
\end{array}
\]

Definition 1.2 A multiplicative structure on $\hat{E}$ consists of a unit $1 \in \hat{E}^0(\text{pt})$ and natural bilinear transformations

(3) \[ \times: \hat{E}^n(N) \times \hat{E}^m(M) \to \hat{E}^{n+m}(N \times M), \]
which are associative, graded commutative, and unital. The maps $I, R$ are required to preserve the external product and unit, while for $a$ we demand

$$a(\theta) \times x = a(\theta \wedge R(x)) \text{ for all } \theta \in \Omega^{n-1}(N; V), \ x \in \hat{E}^m(M).$$

(Here, $\omega \wedge \eta = \text{pr}_1^* \omega \wedge \text{pr}_2^* \eta$ denotes the external product of differential forms.)

Early examples of differential cohomology appeared as the sheaf-theoretic Deligne cohomology (see Gajer [10]) and Cheeger–Simons differential characters [6]. These provide a natural setting to study secondary invariants that take additional geometric structure into account. Later, a stratifold model for ordinary differential cohomology was introduced by Bunke, Kreck, and Schick [2]. Differential extensions of $K$–theory were studied by Lott [12] and Bunke and Schick [3] with which a refinement of the families index theorem may be proven; see Freed and Lott [9]. Another broad class of differential extensions (for Landweber exact cohomology theories) was constructed by Bunke, Schick, Schröder and Wiethaup [5].

Each of these examples carries a multiplicative structure. On the other hand, a general homotopy-theoretic construction of differential extensions was given by Hopkins and Singer [11], but its multiplicative properties remained unclear.

Their study is the main subject of this paper: Theorem 2.5 proves the existence of products for rationally even cohomology theories. As a second main result (Theorem 2.3) we construct explicit integration maps, which are crucial to extend constructions from even degrees to odd degrees. To this end, we introduce differential cohomology for pairs and exhibit a corresponding pair sequence in Theorem 2.2. Finally, in order to prove bilinearity of our products we exhibit a cocycle-based description of addition (Theorem 2.1), which is needed since the abelian group structure in [11] is given by producing a spectrum with homotopy groups $\hat{E}^n(M)$ and the structure maps (in particular, the addition) are only abstractly given, involving choices of functorial sections [11, Equation (4.41)]. In summary, our results provide an accessible approach to (rationally even) differential cohomology based on concrete cocycle constructions.

1A Conventions and notation

1A1 Spectrum By Brown’s representability theorem, the reduced $E$–cohomology $\hat{E}^n(X)$ is represented by a spectrum $(E_n, \varepsilon_n; \ E_n \wedge S^1 \to E_{n+1})$ via pointed homotopy classes $[X, E_n]$ with homeomorphisms as adjoint structure maps $\varepsilon_n^{\text{adj}}: E_n \to \Omega E_{n+1}$. We fix such a choice of spectrum.
1A2 Coefficients Let $C^n(X, A; V) = \prod_{i+j=n} C^i(X, A; V^j)$ denote cochains with coefficients in $V$ and similarly for cohomology and differential forms. Hence an $n$–cochain is a chain map $C_*(X, A) \to V_{*-n}$, where $V_* = V^{-*}$ is a chain complex with zero differential. By $C^*(M, N; V)$ we mean the subcomplex of smooth cochains. Relative differential forms $\omega \in \Omega^n(M, N; V)$ (meaning $\omega_p = 0$ at each $p \in N$) yield smooth cochains via the de Rham homomorphism.

1A3 Integration Let $u \in C^{n+1}((X, A) \times S^1; V)$. Using the Eilenberg–Zilber map $\text{EZ}: C_*(X, A) \otimes C_*(S^1) \to C_*((X, A) \times S^1)$ (see tom Diek [7, page 240]) the integral $\int u$ is the element of $C^n(X, A; V)$ defined on chains $\sigma$ by $(\int u)(\sigma) = u(\text{EZ}(\sigma \otimes S^1))$, for the canonical $1$–cycle $S^1$ on the circle. $\text{EZ}$ is a natural chain map, hence

$$\int \delta u = \delta \int u, \quad f^* \int u = \int (f \times \text{id}_{S^1})^* u. \quad (5)$$

(i) The integral of $\omega \in \Omega^{n+1}(M \times S^1; V)$ along the fiber $S^1$ is also denoted $\int \omega$. Relative forms are integrated by viewing them as absolute forms. In particular, $\int j^* \omega = \int \omega$ for $j: (M \times S^1, M \times 1) \to M \times S^1$.

(ii) For $c: (X, A) \times (S^1, 1) \to (E_{n+1}, pt)$ we let $\int c: (X, A) \to (E_n, pt)$ denote the unique map $(\varepsilon_n^{\text{adj}})^{-1} \circ c^{\text{adj}}$ with

$$\varepsilon_n \circ \left( \int c \times \text{id}_{S^1} \right) = c. \quad (6)$$

(iii) In cohomology, (ii) induces $\int: E^{n+1}((X, A) \times (S^1, 1)) \to E^n(X, A)$ and an absolute integration map $\int: E^{n+1}(X \times S^1) \to E^n(X)$ (see Bunke and Schick [4, page 5]).

Combining (5) and (6), integration of cochains and of maps, as in (ii), are compatible:

$$\int c^* u_n = \left( \int c \right)^* u_{n-1} \quad \text{if} \quad u_{n-1} = \int \varepsilon_{n-1}^* u_n. \quad (7)$$

Viewing forms as cochains, cochain integration extends (i); see Hopkins and Singer [11, Lemma 3.15].

1A4 Left integration Suspensions are on the right, homotopies have their interval $I = [0, 1]$ on the left. Let $\int' u = u(\text{EZ}(I \otimes -))$ denote the left integral of the cochain $u \in C^{n+1}(I \times (X, A); V)$ over the canonical $1$–chain on $I$. Then

$$\int' \delta u + \delta \int' u = u|_{1 \times X} - u|_{0 \times X}, \quad f^* \left( \int' u \right) = \int' (\text{id}_I \times f)^* u. \quad (8)$$

Let $\text{pr}_{i\ldots j\ldots}$ be the projection $X_1 \times X_2 \times \cdots \to X_i \times X_j \times \cdots$ on the indicated factors.
2 Main results

We briefly recall the Hopkins–Singer construction of differential cohomology: Following [11, page 48], fix a spectrum \((E_n, \varepsilon_n)\) representing \(E\) and a choice of fundamental cocycles \(\iota_n \in \tilde{Z}^n(E_n; V)\) satisfying

\[
\iota_{n-1} = \int \varepsilon_{n-1} \iota_n.
\]

These are representatives of the reduced cohomology classes \([\iota_n] \in \tilde{H}^n(E_n; V)\) that represent the reduced Chern character \((A = \text{pt})\) via

\[
\text{ch}[f] = f^* [\iota_n], \quad [f] \in [X, E_n] \cong \tilde{E}^n(X).
\]

Now, for \(N \subset M\) closed, define \(\hat{E}^n(M, N)\) as the set of all equivalence classes of differential cocycles

\[
c: (M, N) \to (E_n, \text{pt})
\]
satisfying

\[
\delta h = \omega - c^* \iota_n \quad \text{for} \ \omega \in \Omega^n(M, N; V), \ h \in C_s^{n-1}(M, N; V).
\]

Here an equivalence \((c_0, \omega, h_0) \sim (c_1, \omega, h_1)\) is a pair

\[
C: I \times (M, N) \to (E_n, \text{pt}), \quad H \in C_s^{n-1}(I \times (M, N); V),
\]

restricting to \((c_0, h_0), (c_1, h_1)\) on the boundary, satisfying \(\delta H = \text{pr}^* \omega - C^* \iota_n\). To a smooth map of pairs \(f: (M_1, N_1) \to (M_2, N_2)\) the functor \(\hat{E}\) associates

\[
\hat{E}^n(f) = f^*: \hat{E}^n(M_2, N_2) \to \hat{E}^n(M_1, N_1), \quad [c, \omega, h] \mapsto [c \circ f, f^* \omega, f^* h],
\]

where \([ \ ]\) denotes equivalence classes. Defining \(I[c, \omega, h] = [c], \ R[c, \omega, h] = \omega, \ a(\theta) = [\text{const}, d\theta, \theta]\) it is shown in [11, Equation (4.57)] that these groups form a differential extension of \(E\) and that the associated flat theory \(\hat{E}_{\text{flat}}^n(M) = \ker(R) \subset \hat{E}^n(M)\) is a cohomology theory.

In the framework of Hopkins–Singer differential cohomology we obtain the following results (always under the assumption rationally even).

**Theorem 2.1** There is an explicit abelian group structure on \(\hat{E}^n(M, N)\) (described in Section 3A) for which \(I, R, a\) and the induced maps (11) are linear.

The proof is given in Section 3B. In Section 4 and Section 5 we then prove Theorem 2.2 and Theorem 2.5, respectively.
**Theorem 2.2** For closed submanifolds $N \subset M$ we have an exact sequence:

$$
\begin{align*}
\delta_1 & : \hat{E}^{n-1}_\text{flat}(M, N) \to \hat{E}^n_\text{flat}(M, N) \\
\delta_2 & : \hat{E}^n_\text{flat}(M, N) \to \hat{E}^n_\text{flat}(N)
\end{align*}
$$

Here $\delta_1 : \hat{E}^{n-1}_\text{flat}(N) \to \hat{E}^{n}_\text{flat}(M, N) \subset \hat{E}^n_\text{flat}(M, N)$ and $\delta_2 : \hat{E}^n_\text{flat}(N) \to \hat{E}^n_\text{flat}(M, N)$, using the connecting homomorphisms for $\hat{E}_\text{flat}$ and $E$.

**Theorem 2.3** The maps from Section 1A3 define linear natural transformations

$$
\int : \hat{E}^{n+1}_\text{flat}((M, N) \times (S^1, 1)) \to \hat{E}^n_\text{flat}(M, N), \quad [c, \omega, h] \mapsto \left[ \int c, \int \omega, \int h \right].
$$

These commute with $I, R, a$ (using (i) and (iii) from Section 1A on forms and $E$–cohomology).

The main work is carried out in Section 6B where we prove our main result.

**Theorem 2.4** There exists a multiplicative structure in even degrees. This product structure is compatible with integration maps $(n, m \text{ even})$.

$$
\iint (x \times y) = x \times (\iiint y) \quad \text{for all } x \in \hat{E}^n_\text{flat}(N), \ y \in \hat{E}^m_\text{flat}(M \times S^1 \times S^1)
$$

A formal argument in Section 6C then yields the following.

**Theorem 2.5** A rationally even multiplicative cohomology theory $E$ admits a multiplicative differential extension with integration satisfying

$$
\int (x \times y) = x \times \left( \int y \right) \quad \text{for all } x \in \hat{E}^n_\text{flat}(N), \ y \in \hat{E}^m_\text{flat}(M \times S^1).
$$

### 3 Addition

Combining the universal coefficient and Künneth theorem with [4, Lemma 3.8] gives $\tilde{H}^k(E_n \times E_m \times \cdots ; V) = 0$ for $k$ odd and $n, m, \ldots$ even. Hence

$$
\delta x = 0 \quad \text{for } x \in \tilde{C}^k(E_n \times E_m \times \cdots ; V) \quad \implies \quad x \in \text{im}(\delta).
$$
We denote by $E_n \times E \times \cdots$ the product spectra $E \times E \times \cdots$ structure maps

$$(E_n \times E_n \times \cdots) \wedge S^1 \to E_{n+1} \times E_{n+1} \times \cdots,$$

$$(x_1, x_2, \ldots) \wedge t \mapsto (\varepsilon_n(x_1 \wedge t), \varepsilon_n(x_2 \wedge t), \ldots).$$

### 3A Construction

In $E$–cohomology, addition is represented (using adjoint structure maps to write $E_i \simeq \Omega^2 E_{i+2}$) by loop composition $\alpha_i : E_i \times E_i \to E_i$ and negation by loop inversion $v_i : E_i \to E_i$ (using either loop coordinate). We agree to use the first or second coordinate for $\alpha_i$, $v_i$, according to whether $i$ is even or odd. Hence for even $n$,

$$\alpha_{n-1} = \int \alpha_n \circ \varepsilon_{n-1}, \quad v_{n-1} = \int v_n \circ \varepsilon_{n-1}. \quad (16)$$

Linearity of (1) implies $\text{ch}[\text{pr}_1] + \text{ch}[\text{pr}_2] = \text{ch}[\alpha_n]$ and $-\text{ch}[\text{id}] = \text{ch}[v_n]$. In terms of the fundamental cocycles, this means that we may pick (we do this only for even $n$) cochains $A_n \in \tilde{C}^{n-1}(E_n \times E_n; V)$, $N_n \in \tilde{C}^{n-1}(E_n; V)$ with

$$\delta A_n = \text{pr}_1^* i_n + \text{pr}_2^* i_n - \alpha_n^* i_n, \quad \delta N_n = -i_n - v_n^* i_n. \quad (17)$$

To ensure (17) also in odd degrees, in view of (5), (7), (9), and (16) we set

$$A_{n-1} = \int \varepsilon_{n-1}^* A_n, \quad N_{n-1} = \int \varepsilon_{n-1}^* N_n. \quad (18)$$

**Definition 3.1** The sum of differential cocycles is defined by

$$(c_1, \omega_1, h_1) + (c_2, \omega_2, h_2) = (\alpha_i(c_1, c_2), \omega_1 + \omega_2, h_1 + h_2 + (c_1, c_2)^* A_i). \quad (19)$$

Define also $0 = (\text{const}, 0, 0)$ and $-(c, \omega, h) = (v_i c, -\omega, -h + c^* N_i)$. These are all differential cocycles by (17) and since the fundamental cocycles are reduced.

### 3B Verification of axioms

With Definition 3.1, induced maps (11) and $I, R, a$ are clearly linear. To check that (19) descends to differential cohomology, suppose $(C_1, H_1) : x_1 \sim x'_1$, $(C_2, H_2) : x_2 \sim x'_2$ are equivalences. Then

$$(\alpha_i(C_1, C_2), H_0 + H_1 + (C_0, C_1)^* A_i) : x_1 + x_2 \sim x'_1 + x'_2.$$
The following two rules for manipulating differential cocycles are proven in the appendix (as Lemmas A.1 and A.2):

\[ h - h' \in \text{im}(\delta) \implies [c, \omega, h] = [c, \omega, h']. \]
\[ C: c_0 \simeq c_1 \text{ (rel } N) \implies [c_0, \omega, h] = [c_1, \omega, h - \int C^* t_n] \in \hat{E}^n(M, N). \]

**Remark 3.2** For \( n \) even, any two choices of \( A_n \) or \( N_n \) differ by a cocycle, which is a coboundary by (15). Combining (5) with (18), this is true also in odd degrees. Hence (20) implies that the addition in differential cohomology depends only on the spectrum \( (E_n, \varepsilon_n) \) and the choice of fundamental cocycles.

**Lemma 3.3** Suppose \( H: I \times E_n \times E_m \times \cdots \to E_i \) is a pointed homotopy and \( c \) is a map \( (M, N) \to (E_n \times E_m \times \cdots, \text{pt}) \). Then \( x = [H_0 \circ c, \omega, h] \), \( y = [H_1 \circ c, \omega, h'] \) in \( \hat{E}^i(M, N) \) agree if there exists \( v_i \in \tilde{Z}^i(E_n \times E_m \times \cdots; V) \) with

\[ h - h' - c^* \int' H^* t_i \equiv c^* v_i \mod \text{im}(\delta), \]

and one of the following conditions is satisfied:

(i) \( i \) and \( n, m, \ldots \) are even integers.

(ii) \( i = n = m = \cdots \) are odd and there exists \( v_{i+1} \in \tilde{Z}^{i+1}(E_{i+1} \times E_{i+1} \times \cdots; V) \) with

\[ v_i = \int (\varepsilon_t E \times E \times \cdots)^* v_{i+1}. \]

**Proof** Given (i), \( \delta v_i = 0 \) and (15) shows that \( v_i \) is a coboundary. If (ii) is satisfied, then \( v_{i+1} \) is a coboundary by (i) and (5) implies that \( v_i = \int \varepsilon_t^* v_{i+1} \) is also a coboundary. In each case, the cochain (22) is a coboundary. Hence

\[ [H_0 \circ c, \omega, h] = [H_1 \circ c, \omega, h - c^* \int' H^* t_i] \quad \text{by (8), (21)} \]
\[ = [H_1 \circ c, \omega, h'] \quad \text{by (20)}. \]

**Theorem 2.1** There is an explicit abelian group structure on \( \hat{E}^n(M, N) \) (described in Section 3A) for which \( I, R, a \) and induced maps (11) are linear.

**Proof** Expressing that \( E \)-cohomology is abelian group-valued in terms of representing maps leads to homotopies (chosen only for even degrees \( n \))

\[ H_n^{\text{ass.}}: \alpha_n(\alpha_n \times \text{id}) \simeq \alpha_n(\text{id} \times \alpha_n); \quad H_n^{\text{neg.}}: \alpha_n(\text{id}, v_n) \simeq \text{const}, \]
\[ H_n^{\text{zer.}}: \alpha_n(\text{id}, \text{const}) \simeq \text{id}; \quad H_n^{\text{com.}}: \alpha_n \circ \text{flip} \simeq \alpha_n. \]
In view of (16), corresponding homotopies in degree \( n - 1 \) may be defined by

\[
H_{n-1}^{\text{ass}} = \int H_n^{\text{ass}} \circ (\text{id}_I \times \varepsilon_{n-1}^{E \times E}), \quad H_{n-1}^{\text{neg}} = \int H_n^{\text{neg}} \circ (\text{id}_I \times \varepsilon_{n-1}),
\]

(23)

\[
H_{n-1}^{\text{zer}} = \int H_n^{\text{zer}} \circ (\text{id}_I \times \varepsilon_{n-1}), \quad H_{n-1}^{\text{com}} = \int H_n^{\text{com}} \circ (\text{id}_I \times \varepsilon_{n-1}^{E \times E}).
\]

For \( x_j = [c_j, \omega_j, h_j] \) in \( \hat{E}^j(M, N) \), \( j = 1, 2, 3 \), we must show

\[
(x_1 + x_2 + x_3) = x_1 + (x_2 + x_3), \quad x_1 + (-x_1) = 0, \quad x_1 + 0 = x_1, \quad x_2 + x_1 = x_1 + x_2.
\]

Unwinding Definition 3.1 leads in each case to differential cocycles \( x, y \) we wish to prove are equivalent; eg unwinding the commutativity axiom leads to

\[
x = (\alpha_i(c_2, c_1), \omega_2 + \omega_1, h_2 + h_1 + (c_2, c_1)^* A_k),
\]

\[
y = (\alpha_i(c_1, c_2), \omega_1 + \omega_2, h_1 + h_2 + (c_1, c_2)^* A_k).
\]

Each of these axioms holds for differential forms and is exhibited in differential cohomology by a respective application of Lemma 3.3 to the cochains

\[
v_k^{\text{ass}} = \text{pr}_{12}^* A_k + (\alpha_k \times \text{id})^* A_k - \text{pr}_{23}^* A_k - \int' (H_k^{\text{ass}})^* i_k,
\]

\[
v_k^{\text{com}} = \text{flip}^* A_k - A_k - \int' (H_k^{\text{com}})^* i_k,
\]

\[
v_k^{\text{neg}} = N_k + (\text{id}, v_k)^* A_k - \int' (H_k^{\text{neg}})^* i_k,
\]

\[
v_k^{\text{zer}} = (\text{id}, \text{const})^* A_k - \int' (H_k^{\text{zer}})^* i_k,
\]

the maps \( c^{\text{ass}} = (c_1, c_2, c_3), c^{\text{com}} = c^{\text{neg}} = (c_1, c_2), c^{\text{zer}} = c_1 \), and homotopies \( H = H_i^{\text{ass}}, H_i^{\text{com}}, H_i^{\text{neg}}, H_i^{\text{zer}} \). Our choice (17) and (8) ensure \( \delta v_k = 0 \) in each case. If \( i \) is odd, condition (ii) of Lemma 3.3 holds by (9), (18), and (23).

Assuming the coefficients \( E^* \)(pt) are countably generated, [4, Theorem 3.10] implies that \( \hat{E}^* \), with the above abelian group structure and the integration maps from Section 5, is isomorphic to the construction in [11].

### 4 Long exact sequence of pairs

**Proof of Theorem 2.2** At every place except \( \hat{E}^n(M) \) the exactness follows by combining the exactness of (2) with the exact pair sequences for \( E, \hat{E}^{\text{flat}} \). Suppose therefore that \( (c, \omega, h) \) is a cocycle on \( M \) with an equivalence \( (C, H) \) from \( (c, \omega, h)|_N \)

*Algebraic & Geometric Topology, Volume 15 (2015)*
to \((\text{const}, 0, 0)\). Let \(\phi: I \to I\) be smooth strictly increasing with \(\phi|_{[0, 1/4]} = 0, \phi(1) = 1\). Pulling \(C, H\) back along \(\phi\), we may suppose

\[
C|_{[0, 1/4] \times N} = c|_N \circ \text{pr}_2, \quad H|_{[0, 1/4] \times N} = \text{pr}_2^* h|_N.
\]

Applying Lemma A.3 to \(A = 0 \times M \cup [0, 1/4] \times N, \ B = \{0, 1\} \times N\) and \(\text{pr}_2^* h|_A, \ H\), we find \(G \in C_{s-1}^n(0 \times M \cup I \times N; V)\) with \(G|_A = \text{pr}_2^* h|_A, \ G|_B = H\).

The maps \(c\) and \(C\) can be glued to a map \(D\) on \(0 \times M \cup I \times N\). In view of (35), cocycles are invariant under \(\text{sd}\). Hence, to prove \(\delta G = \text{pr}^* \omega - D^* t_n\), it suffices to consider chains contained entirely in \(A\) or in \(B\), which reduces to the corresponding facts for \(h\) and \(H\). Since \(N \subset M\) is a cofibration, we find a retraction \(r: I \times M \to 0 \times M \cup I \times N\). Deforming \(r\) relative to the closed subset \(M \times 0 \cup I \times N\), we may suppose that \(r\) is smooth. The pullback of \((G, D)\) along \(r\) satisfies \(\delta r^* G = \text{pr}^* \omega - (Dr)^* t_n\) and therefore represents an equivalence \((c, \omega, h) \sim (D \circ r|_{M \times 1}, \omega, r^* G|_{M \times 1})\) to an element of \(\hat{E}^n(M, N)\).

\[\blacksquare\]

## 5 Integration maps

Combining (5), (7), and (9) shows that \((\int c, \int \omega, \int h)\) from (13) is indeed a differential cocycle. If \((C, H)\) is an equivalence \(x_0 \sim x_1\), then we have \(\delta \int H = \text{pr}^* \omega - (\int C)^* t_n\) and so \(\int x_0 \sim \int x_1\). Hence (13) is well defined.

**Theorem 2.3** The maps from Section 1A3 define linear natural transformations

\[
(13) \quad \int: \hat{E}^{n+1}(M, N) \times (S^1, 1) \to \hat{E}^n(M, N), \quad [c, \omega, h] \mapsto \left[\int c, \int \omega, \int h\right].
\]

These commute with \(I, R, a\) (using (i) and (iii) from Section 1A on forms and \(E\)-cohomology).

**Proof** Naturality for smooth \(f: M_1 \to M_2\) means

\[
\hat{E}^n(f)\left(\int [c, \omega, h]\right) = \int \hat{E}^{n+1}(f \times \text{id}_{S^1})[c, \omega, h],
\]

and follows from (5). Linearity of (13) asserts an equality

\[
(24) \quad \int [\alpha_i(c_1, c_2), \omega_1 + \omega_2, h_1 + h_2 + (c_1, c_2)^* A_i] = [\alpha_{i-1}(\int c_1, \int c_2), \int \omega_1 + \int \omega_2, \int h_1 + \int h_2 + (\int c_1, \int c_2)^* A_{i-1}].
\]
If $i = n$ is even, (7), (18) imply $\int (c_1, c_2)^* A_n = (\int c_1, \int c_2)^* A_{n-1}$ and by (16) we have $\int \alpha_i (c_1, c_2) = \alpha_{i-1} (\int c_1, \int c_2)$, so (24) holds. Addition in $E$–cohomology may be performed using either loop coordinate, so we may select a homotopy

$$H: \alpha_{i-1} \circ (\varepsilon_{i-1}^{\text{adj}} \times \varepsilon_{i-1}^{\text{adj}})^{-1} \simeq (\varepsilon_{i-1}^{\text{adj}})^{-1} \circ \Omega \alpha_i.$$  

If $i = n - 1$ is odd, applying (21) with $H \circ (c_1^{\text{adj}}, c_2^{\text{adj}})$ reduces us by (20) to showing that the following is a coboundary (which follows from (15)):

$$A_i - (\varepsilon_{i-1}^{\text{adj}} \times \varepsilon_{i-1}^{\text{adj}})^* \int H^* l_i + \int \varepsilon_{i}^* A_{i+1}.$$  

\[\square\]

**Corollary 5.1** From (13) we obtain unique linear natural transformations

(25)

$$\int: \widehat{E}^{n+1}(M \times S^1) \to \widehat{E}^n(M)$$

satisfying the following two conditions:

(i) The map (13) is the composition of (25) with $\widehat{E}^{n+1}(j)$.

(ii) $\int \text{pr}_1^* = 0$ for the projection $\text{pr}_1: M \times S^1 \to M$.

Here, $j: M \times S^1 \to M \times (S^1, 1)$. Moreover, (25) commutes with $I, R, a$.

**Proof** Write $i: M \times 1 \to M \times S^1$ and let $x \in \widehat{E}^{n+1}(M \times S^1)$. By exactness of (12), we have $x - \text{pr}_1^* i^* x = j^* y$ for some class $y \in \widehat{E}^{n+1}(M \times S^1, M \times 1)$. Then

(26)

$$\int x = (ii) \int (x - \text{pr}_1^* i^* x) = (i) \int y$$

shows uniqueness and gives a formula for existence. To check that (26) is well defined, assume $j^* y = 0$. Since $i$ is a section of $\text{pr}_1$, the exact sequence of pairs in $E$–cohomology implies that $E^{n+1}(j)$ is injective, so $I(y) = 0$. By (2), write $y = a(\theta)$. Since $0 = j^* y = a(j^* \theta)$, write $j^* \theta = \text{ch}(t)$ for some $t \in E^n(M \times S^1)$. Using that (1) is compatible with suspension, we have

$$\int y = \int a(\theta) = a\left(\int \theta\right) = a\left(\int j^* \theta\right) = a\left(\int \text{ch}(t)\right) = a\left(\text{ch}\left(\int t\right)\right) = 0,$$

where the second equality follows from Theorem 2.3, and the last from (2). This proves well definedness. Linearity and compatibility of (25) with $I, R, a$ is inherited from the corresponding properties in Theorem 2.3.  

\[\square\]
5A Integration from the left

Define left integration $\int' = \int \tau^*$ using the flip $\tau$ of the two circles in $M \times S^1 \times S^1$.

**Lemma 5.2** $\int \int \tau^* = - \int \int : \bar{E}^{n+2}(M \times (S^1, 1) \times (S^1, 1)) \to \bar{E}^n(M)$ (n even).

**Proof** The respective assertion is true for differential forms (graded commutativity), cochains (by the symmetry properties of EZ), and maps (if $t: E_n \approx \Omega^2 E_{n+2} \to \Omega^2 E_{n+2} \approx E_n$ flips the two loop coordinates, we have $t \circ \int c = \int c \circ \tau$). Hence, selecting a homotopy $H: v_n \simeq t$, we may apply Lemma 3.3(i) with $v_k = \int' H^* \iota_k - (v_k)^* N_k^1$, $H$, $\int c$, to prove equality of

$$x = \left[ t \int c, \int \tau^* \omega, \int \tau^* h \right], \quad y = \left[ v_n \int c, - \int \omega, - \int h + \left( \int c \right)^* N_n \right],$$

provided we have $\delta v_k = 0$, which follows from (8), (17), and the observation

$$t^* \iota_k = t^* \int (\varepsilon_k \times \text{id}_{S^1})^* \varepsilon_{k+1}^* \iota_{k+2} = \int \tau^* (\varepsilon_k \times \text{id}_{S^1})^* \varepsilon_{k+1}^* \iota_{k+2}$$

$$= - \int (\varepsilon_k \times \text{id}_{S^1})^* \varepsilon_{k+1}^* \iota_{k+2} = - \iota_k,$$

where we have used (9) and the assertion $\int \int = - \int \tau^*$ for cochains. $\square$

**Corollary 5.3** $\int \int \tau^* = - \int \int : \bar{E}^{n+2}(M \times S^1 \times S^1) \to \bar{E}^n(M)$ (n even).

6 Products

6A Construction in even degrees

The unit and the multiplication in $E$–cohomology may be represented by pointed maps

$$\mu_{nm}: E_n \wedge E_m \to E_{n+m}, \quad u: pt \to E_0.$$

Since (1) is multiplicative, $\text{ch}[\text{id}_{E_n}] \times \text{ch}[\text{id}_{E_m}] = \text{ch}[\text{id}_{E_{n+m}}], \text{ch}[u] = 1$. Hence we find cochains $M_{n,m} \in \tilde{C}^{n+m-1}(E_n \wedge E_m; V)$ and $U \in \tilde{C}^{-1}(pt; V)$ with

$$\delta M_{n,m} = \iota_n \times \iota_m - \iota_{n+m}, \quad \delta U = \omega_{pt} - u^* \iota_0,$$

where $\omega_{pt} = 1 \in \Omega^0(pt)$. The definition of corepresentable functor on $M$ is rather technical, so we will not recall it here (see [1] or [13, Section 7]); an example is the smooth cochain functor $(M, N, \ldots) \mapsto C^k_\delta(M \times N \times \cdots; W)$ on manifolds with corners $C = \text{Man} \times \text{Man} \times \cdots$ with models $(\Delta^n, \Delta^m, \cdots)$.
Theorem  (Acyclic models)  Let $F, G$ be contravariant functors from a category $C$ equipped with a full subcategory of models $M$ to non-negative real cochain complexes. Suppose $G$ is corepresentable with respect to the models and that $H^{*+1}(F(M)) = 0$ for all $M \in M$. Then any two natural chain maps $f^*, g^* : F^* \to G^*$ with $H^0(f) = H^0(g)$ are naturally chain homotopic. Moreover, any two natural chain homotopies between natural chain maps are naturally chain homotopic.

Taking $F(M, N) = \Omega(M; V^i) \otimes \Omega(N; V^j), G(M, N) = C_*(M \times N; V^i \otimes V^j)$ and the chain maps $\wedge$ and $\cup$ gives natural chain homotopies $B_{ij}$ satisfying

$$\delta B_{ij}(\omega_1 \otimes \omega_2) + B_{ij} d(\omega_1 \otimes \omega_2) = \omega_1 \bar{\omega}_2 - \omega_1 \wedge \omega_2, \quad \omega_1 \in \Omega(M; V^i), \omega_2 \in \Omega(N; V^j).$$

Combining these as $B(\sum_i \omega_i \otimes \sum_j \omega_j) = \sum_{i,j} B_{ij}(\omega_i \otimes \omega_j)$, we get a natural chain homotopy $B$ for the case of graded coefficients satisfying

$$\delta B(\omega_1, \omega_2) + B d(\omega_1 \otimes \omega_2) = \omega_1 \bar{\omega}_2 - \omega_1 \wedge \omega_2.$$  

Similarly, using $F(M, N) = C_*(N \times M; V), G$ above, and the chain maps $\times$ and $\tau^* \times$, the acyclic models theorem proves that the product of cochains is graded commutative up to natural chain homotopy $D$

$$\delta D(\omega \otimes v) + D \delta(\omega \otimes v) = \omega \times v - (-1)^{|\omega| |v|} \tau^* (v \times u).$$

Since the external product $\bar{\omega}$ is graded commutative, both $(-1)^{|\omega_0| |\omega_1|} \tau^* B(\omega_0, \omega_1) - D(\omega_1, \omega_0)$ and $B(\omega_1, \omega_0)$ define natural chain homotopies between

$$\Omega(M; V) \otimes \Omega(N; V) \to C_*(N \times M; V), \quad (\omega_0, \omega_1) \mapsto \omega_1 \bar{\omega}_0, \quad \omega_1 \wedge \omega_0,$$

and are so themselves chain homotopic. In particular, for closed forms $\omega_0, \omega_1$

$$B(\omega_1, \omega_0) \equiv (-1)^{|\omega_0| |\omega_1|} \tau^* B(\omega_0, \omega_1) - D(\omega_1, \omega_0) \mod \text{im}(\delta).$$

Since $B(\omega_{pt}, -)$ and 0 are both natural chain homotopies $\id \simeq \id$, the acyclic models theorem implies that they are themselves chain homotopic. Hence

$$B(\omega_{pt}, \omega) \in \text{im}(\delta) \quad \text{for all forms } \omega \text{ with } d\omega = 0.$$

Definition 6.1  The unit 1 $\in \hat{E}^0(\text{pt})$ is defined by $[u, \omega_{pt}, U]$. The product $x_1 \times x_2$ of the differential cocycles $x_1 = (c_1, \omega_1, h_1), x_2 = (c_2, \omega_2, h_2)$ is

$$\left(\mu_{nm}(c_1 \times c_2), \omega_1 \bar{\omega}_2, B(\omega_1, \omega_2) + h_1 \wedge \omega_2 + \omega_1 \wedge h_2 - h_1 \wedge \delta h_2 + (c_1 \times c_2)^* M_{n,m}\right).$$

Naturality of the products follows from the naturality of $B, \bar{\omega}, \delta, \text{ and } \times$. Clearly $R$ and $I$ preserve the external product. (28), (29) ensure that the unit and $x_1 \times x_2$ are
indeed differential cocycles. Suppose we have equivalences \((C_1, H_1): x_1 \sim x_1'\) and \((C_2, H_2): x_2 \sim x_2'\). Then \(C = \mu_{n,m}(C_1 \times C_2)\) and the cochain

\[
H = B(\text{pr}^* \omega_1 \otimes \text{pr}^* \omega_2) + H_1 \times \text{pr}^* \omega_2 + \text{pr}^* \omega_1 \times H_2 - H_1 \times \delta H_2 + (C_1 \times C_2)^* M_{n,m}
\]

show \(x_1 \times x_2 \sim x_1' \times x_2'\). Hence the product descends to a map (3) on differential cohomology.

### 6B Verification of axioms

Let \(\pi(x, y, z) = (x, y, z)\).

**Theorem 2.4** We have a multiplicative structure in even degrees. This product structure is compatible with integration maps (14).

**Proof** Let \(x_j = [c_j, \omega_j, h_j]\) for classes \(x_1 \in \hat{E}^n(N), x_2 \in \hat{E}^m(M), x_3 \in \hat{E}^l(L)\) and even integers \(n, m, l\).

**(i) Bilinearity** Let \(x = x_1 \times (x_2 + x_3), y = x_1 \times x_2 + x_1 \times x_3\). Unwinding Definitions 3.1 and 6.1, we see that we must compare the maps

\[
\mu_{nm}(\text{id} \times \alpha_m) \circ c, \quad \alpha_{n+m} \circ (\mu_{nm} \times \mu_{nm}) \circ \pi \circ c, \quad \text{where } c = c_1 \times c_2 \times c_3,
\]

differential forms \(\omega = \omega_1 \wedge (\omega_2 + \omega_3) = \omega' = \omega_1 \wedge \omega_2 + \omega_1 \wedge \omega_3\), and cochains

\[
h = B(\omega_1, \omega_2 + \omega_3) + h_1 \times (\omega_2 + \omega_3) + \omega_1 \times (h_2 + h_3 + (c_2, c_3)^* A_m)
\]

\[
- h_1 \times \delta(h_2 + h_3 + (c_2, c_3)^* A_m) + (c_1 \times \alpha(c_2, c_3))^* M_{nm},
\]

\[
h' = B(\omega_1, \omega_2 + \omega_3) + h_1 \times \omega_2 + h_1 \times \omega_3 + \omega_1 \times (h_2 + h_3) - h_1 \times \delta(h_2 + h_3)
\]

\[
+ (c_1 \times c_2)^* M_{nm} + (c_1 \times c_3)^* M_{nm} + (\mu(c_1 \times c_2), \mu(c_1 \times c_3))^* A_{n+m}.
\]

Expressing that the product in \(E\)–cohomology is bilinear leads to a homotopy

\[
H: \mu_{nm}(\text{id} \times \alpha_m) \simeq \alpha_{n+m}(\mu_{nm} \times \mu_{nm}) \pi.
\]

Using bilinearity of \(B\) and of \(\times\) for cochains shows that \(h - h' - \epsilon^* \int H^* t_{n+m}\) is the pullback along \(c\) of the cochain \(v\) on \(E_n \times E_m \times E_m\) given by

\[
t_n \times A_m + ((\text{id} \times \alpha_m)^* - \text{pr}_{12}^* - \text{pr}_{13}^*) M_{nm} - \pi^* (\mu_{nm} \times \mu_{nm}) A_{n+m} - \int H^* t_{n+m}.
\]

The cochain \(v\) is closed by (8), (17), and (28). We conclude \(x = y\) by an application of Lemma 3.3(i) to \(H, c, \) and \(v\).

*Algebraic & Geometric Topology, Volume 15 (2015)*
(ii) **Commutativity**  We have $\omega_1 \wedge \omega_2 = \tau^*(\omega_2 \wedge \omega_1)$. Combining (30), (31) with (20) shows that $y = \tau^*(x_2 \times x_1) = [\mu_{mn}(c_2, c_1) \circ \tau, \omega_1 \wedge \omega_2, \theta']$, where

$$h' = B(\omega_1, \omega_2) + h_1 \wedge \omega_2 + \omega_1 \wedge h_2 - h_1 \wedge \delta h_2 + (c_2 \wedge c_1) * \tau^* M_{mn} + (c_2 \wedge c_1) * D(t_m, t_n).$$

Then $y = x_1 \times x_2$ by Lemma 3.3(i), applied to a homotopy $H: \mu_{mn} \circ \tau \simeq \mu_{nm}$, $c = c_1 \times c_2$, and the following closed (by (8), (28), and (30)) cochain:

$$v = \tau^* D(t_m, t_n) + \tau^* M_{mn} - M_{nm} - \int H^* t_{n+m}.$$  

(iii) **Unitality**  Equation (32) and Lemma 3.3(i) applied to $H: \mu_{0n} (u \times \text{id}) \simeq \text{id}$, the cochain $v_n = U \times t_n + (u \times \text{id}) M_{0n} - \int H^* t_n$, and $c = c_1$ show $1 \times x_1 = x_1$.

(iv) **Associativity**  This property follows from Lemma 3.3(i) applied to $c = c_1 \times c_2 \times c_3$, a homotopy $H: \mu_{n, m+l} (\text{id} \times \mu_{ml}) \simeq \mu_{n+m, l} (\mu_{nm} \times \text{id})$, and $v$ given by

$$M_{n, m+l} - \mu_{n, m+l}^* (t_n \times M_{ml}) - M_{n+m, l} - \mu_{n+m, l}^* (M_{nm} \times t_l) - \int H^* t_{n+m+l}.$$  

(v) **Compatibility with $a$**  Let $\theta \in \Omega^{n-1}(N; V)$. Applying (20) to $B(d\theta, \omega_2) \equiv \theta \wedge \omega_2 - \theta \wedge \omega_2$ and $d\theta \wedge h \equiv \theta \wedge \delta h$ (Leibniz’ rule) modulo coboundaries gives

$$a(\theta) \times x_2 = [\mu_{nm}(\text{const} \times c_2), d\theta \wedge \omega_2, \theta \wedge \omega_2 + (\text{const} \times c_2) * M_{nm}].$$

Then $a(\theta) \times x_2 = a(\theta \wedge \omega_2)$ by Lemma 3.3(i) applied to $c = \text{const} \times c_2$, a homotopy $H: \mu_{nm}(\text{const}, \text{id}) \simeq \text{const}$, and the cocycle

$$v = (\text{const} \times \text{id})^* M_{nm} - \int H^* t_{n+m}.$$  

(vi) **Compatibility with integration** (14)  Let $[c_1, \omega_1, h_1] \in \hat{E}^n(N)$ and $[c_2, \omega_2, h_2] \in \hat{E}^m(M \times S^1 \times S^1)$ for $n, m$ even. Unwinding the definitions, we see that we need to compare

$$x = \left[ \iint \mu(c_1 \times c_2), \iint (\omega_1 \wedge \omega_2), \theta \right], \quad y = \left[ \mu(c_1 \times \iint c_2), \omega_1 \wedge \left( \iint \omega_2 \right), \theta' \right]$$

for the cochains $h$ and $h'$ given by

$$
\iint (B(\omega_1, \omega_2) + \omega_1 \times h_2 + h_1 \times \omega_2 - h_1 \times \delta h_2 + (c_1 \times c_2) * M_{n,m}),
$$

$$
B(\omega_1, \iint \omega_2) + h_1 \times \left( \iint \omega_2 \right) + \omega_1 \times \left( \iint h_2 \right) - h_1 \times \delta \left( \iint h_2 \right) + (c_1 \times \iint c_2) * M_{n,m-2}.
$$

Both $\iint B(-, -)$ and $B(-, \iint -)$ define natural chain homotopies between the same chain maps. By acyclic models, they are themselves chain-homotopic and hence
differ on closed forms only by coboundary. Integration of forms is compatible with $\wedge$ and integration of cochains is compatible with $\times$ (since the Eilenberg–Zilber map is a section of the Alexander–Whitney map, which is used to define the product of cochains), so

$$h - h' = \int \left( c_1 \times c_2 \right)^* M_{n,m} - (c_1 \times \int c_2)^* M_{n,m-2} \mod \text{im}(\delta).$$

Since products in $E$–cohomology are compatible with suspension we may select a homotopy $H: \mu_{nm}(\text{id} \times \varepsilon_{m-1} \Sigma \varepsilon_{m-2}) \simeq \varepsilon_{n+m-1} \Sigma \varepsilon_{n+m-2} \Sigma^2 \mu_{n,m-2}$. Applying Lemma 3.3(i) with $c = c_1 \times \int c_2$, $\int \int H$, and the cochain

$$v = \int \left( \text{id} \times \varepsilon_{m-1} \circ \Sigma \varepsilon_{m-2} \right)^* M_{nm} - M_{n,m-2} - \int \left( \int \int H \right)^* t_{n+m-2}$$

proves $x = y$. Here, $\delta v = 0$ follows from (5), (8), and (28). \hfill $\Box$

6C Extension to odd degrees

Theorem 2.5 is obtained from Theorem 2.4 by the following general principle.

**Theorem 6.2** Suppose $\hat{E}$ is a differential extension of $E$ such that we have:

(i) Long exact sequences (12) for every closed submanifold $N \subset M$.

(ii) Integration maps as in Theorem 2.3. By (i), these induce an absolute integration (25) for which we assume Corollary 5.3.

(iii) A multiplicative structure on $\hat{E}$ in even degrees satisfying (14).

Then there is a unique extension of the multiplicative structure to all degrees, compatible with integration:

$$\int (x \times y) = x \times \left( \int y \right) \quad \text{for all } x \in \hat{E}^n(N), \ y \in \hat{E}^m(M \times S^1).$$

**Lemma 6.3** Integration $f: \hat{E}^{n+1}(M \times S^1, M \times 1) \to \hat{E}^n(M)$ is surjective. The kernel consists of all $a(\theta), \ \theta \in \Omega^0_{cl}(M \times S^1, M \times 1; V), \text{with } [\int \theta] \in \text{im}(c^n)$.

**Proof** Let $x \in \hat{E}^n(M)$. The isomorphism $I: E^{n+1}(M \times S^1, M \times 1) \cong E^n(M)$ and the surjectivity of $I$ show that there is $X \in \hat{E}^{n+1}(M \times S^1, M \times 1)$ with

$$\int I(X) = I(x).$$
According to the lemma, every $y$ (The last equality is by Corollary 5.3).

(14) implies (33). Combined with Lemma 6.3, the verification of bilinearity, unitality, associativity, and graded commutativity (note our choice of sign in (34)) may therefore be reduced to the even-degree case. It remains to check

$$a(\theta) \times x = a(\theta \wedge R x) \quad \text{for } \theta \in \Omega^{n-1}(N; V), \ x \in \hat{E}^m(M).$$

Proof of Theorem 6.2 Considering the definition (34) case by case, we see that (14) implies (33). Combined with Lemma 6.3, the verification of bilinearity, unitality, associativity, and graded commutativity (note our choice of sign in (34)) may therefore be reduced to the even-degree case. It remains to check

$$a(\theta) \times x = a(\theta \wedge R x) \quad \text{for } \theta \in \Omega^{n-1}(N; V), \ x \in \hat{E}^m(M).$$
in case $n$ or $m$ are odd. For $\theta \in \Omega^{n-1}(N; V)$ we find $\kappa \in \Omega^n(N \times S^1; V)$ with $\int \kappa = \theta$. The verification reduces to even degrees; e.g. for $n$ odd and $m$ even

$$a(\theta) \times x = \int (a(\kappa) \times x) = \int a(\kappa \times Rx) = a\left(\int \kappa \times Rx\right) = a(\theta \times Rx).$$

\section*{Appendix: Technical lemmas}

\begin{lemma}
For every smooth cochain $v \in C^n(M, N)$ there exists $E \in Z^n(I \times (M, N))$ with restrictions $E|_0 = 0$ and $E|_1 = \delta v$. Hence, if $(c, \omega, h)$ is a differential cocycle and $h - h'$ is a coboundary, we have $(c, \omega, h) \sim (c, \omega, h')$.
\end{lemma}

\begin{proof}
For the zeroth vertex $e_1 \in \Delta^n$ and $\sigma = (\sigma_1, \sigma_2): \Delta^n \rightarrow I \times M$ we define $E(\sigma) = \sigma_1(e_1)v(\partial \sigma_2)$. Since $\sigma_1d^i(e_1)$ is independent of $i$, $E$ is a cocycle:

$$E(\partial \sigma) = \sum (-1)^i(\sigma_1d^i)(e_1)v(\partial(\sigma_2 \circ d^i)) = \sigma_1(e_1)v(\partial \partial \sigma_2) = 0.$$

Applying this to each factor, we deduce a version with graded coefficients. In (20) it suffices for $h - h'$ to bound a singular cochain (since $H^i(M, N; V) \cong H^i_s(M, N; V)$ it follows that $h - h'$ also bounds a smooth cochain then).

\end{proof}

\begin{lemma}
For a homotopy $C: c_0 \simeq c_1$ (rel $N$) and $[c_0, \omega, h] \in \hat{E}^n(M, N)$ we have $[c_0, \omega, h] \sim [c_1, \omega, h']$ for $h' = h - \int C^*t_n$.
\end{lemma}

\begin{proof}
Define a homotopy $K: C \simeq c_1 \circ pr_2$ by $K(s, t, m) = C(t, m)$ for $s \leq t$ and $K(s, t, m) = C(s, m)$ for $s \geq t$ and let $H = pr_2^* h' + \int K^*t_n$. Using (8) and $\delta h' = \omega - c_1^*t_n$, we have $\delta H = pr_2^* \omega - C^*t_n$ and $H|_0 = h' + \int C^*t_n = h$, so the pair $(C, H)$ shows $[c_0, \omega, h] = [c_1, \omega, H|_1]$. Since $\int \delta h' \equiv 0$ for forms, we get

$$H|_1 = h' + \int pr_2^* c_1^*t_n = h' + \int pr_2^* (\omega - \delta h') = h' - \delta \int pr_2^* h'.$$

Hence (20) implies $[c_1, \omega, H|_1] = [c_1, \omega, h']$. \qed

\begin{lemma}
Let $M = A \cup B$ for open $A, B \subset M$. Any $u \in C^n_s(A; V)$, $v \in C^n_s(B; V)$ with common restriction to $A \cap B$ may be extended to $C^n_s(A \cup B; V)$.
\end{lemma}

\begin{proof}
We begin with the ungraded case, so $V$ is just a vector space and $u, v$ are $V$–valued cochains. Define a subdivision operator on smooth $n$–chains by

$$sd(\sigma_{n+1}) = (-1)^n \partial \sigma + \sigma_{n+1} . \quad \sigma_{n+1}: \Delta^n \rightarrow M,$$
where $\sigma = \sigma_{n+1} \circ \pi$ for $\pi(t_0, \ldots, t_{n+1}) \mapsto \left(t_0 + \frac{t_{n+1}}{n+1}, \ldots, t_n + \frac{t_{n+1}}{n+1}\right)$. Since the diameters tend to zero, after a finite minimal number $m(\sigma)$ of subdivisions any simplex $\sigma$ becomes a chain $\sum n_k \tau_k$ with every $\tau_k$ entirely in $A$ or in $B$. Define a $V$–valued cochain $w$ by

$$w(\sigma) = \sum n_k \begin{cases} u(\tau_k) & \text{if } \tau_k(\Delta^n) \subset A, \\ v(\tau_k) & \text{if } \tau_k(\Delta^n) \subset B. \end{cases}$$

By the minimality assumption, $w$ restricts to $u$ and $v$. This concludes the proof in the ungraded case. For the graded case, suppose $u = (u^i)_{i \in \mathbb{Z}}$ and $v = (v^i)_{i \in \mathbb{Z}}$ where $u^i \in C^i_s(A; V^{n-i})$ and $v^i \in C^i_s(B; V^{n-i})$. By assumption, $u^i$ and $v^i$ agree on $A \cap B$, hence by the already proven case we find $w^i \in C^i_s(A \cup B; V^{n-i})$, extending $u^i$ and $v^i$. The family $w = (w^i)_{i \in \mathbb{Z}}$ is then the sought-for cochain. \hfill $\square$
