A rooted-trees $q$-series lifting a one-parameter family of Lie idempotents

Frédéric Chapoton
A rooted-trees $q$-series lifting a one-parameter family of Lie idempotents

Frédéric Chapoton

We define and study a series indexed by rooted trees and with coefficients in $\mathbb{Q}(q)$. We show that it is related to a family of Lie idempotents. We prove that this series is a $q$-deformation of a more classical series and that some of its coefficients are Carlitz $q$-Bernoulli numbers.

1. Introduction

The aim of this article is to introduce and study a series $\Omega_q$ indexed by rooted trees, with coefficients that are rational functions of the indeterminate $q$.

The series $\Omega_q$ is in fact an element of the group $G_{PL}$ of formal power series indexed by rooted trees, which is associated to the pre-Lie operad by a general functorial construction of a group from an operad. As there is an injective morphism of operads from the pre-Lie operad to the dendriform operad, there is an injection of groups from $G_{PL}$ to the group $G_{Dend}$, which is a group of formal power series indexed by planar binary trees. This means that each series indexed by rooted trees can be mapped to a series indexed by planar binary trees, in a nontrivial way.

There is a conjectural description of the image of this injection of groups (see [Chapoton 2007, Corollary 5.4]). This can be stated roughly as the intersection in a bigger space (spanned by permutations) of the dendriform elements with the Lie elements. The inclusion of the image in the intersection is known, but the converse is not.

One starting point of this article was the existence of a one-parameter family of Lie idempotents belonging to the descent algebras of the symmetric groups [Duchamp et al. 1994; Krob et al. 1997]. As Lie idempotents, these are in particular Lie elements. As elements of the descent algebras, these are also dendriform elements. Therefore, according to the conjecture stated above, they should belong to the image of $G_{PL}$ in $G_{Dend}$.

Keywords: tree series, operads, Lie idempotents, Bernoulli–Carlitz numbers.
This work received support from the ANR grant BLAN06-1_136174.
Bypassing the conjecture, we prove this by exhibiting an element $\Omega_q$ of $G_{PL}$ and then showing that its image is the expected sum of Lie idempotents.

We then obtain several results on $\Omega_q$. First, we prove that the series $\Omega_q$ has only simple poles at nontrivial roots of unity and, in particular, can be evaluated at $q = 1$. Then we show that $\Omega_q$ is a $q$-deformation of a classical series $\Omega$ which is its value at $q = 1$. We also compute the value at $q = 0$ and the appropriate limit value when $q = \infty$.

We then consider the images of $\Omega_q$ in some other groups. There are two morphisms of groups from $G_{PL}$ to usual groups of formal power series in one variable, both coming by functoriality from quotient operads of pre-Lie. Looking at linear trees only, that is, using the quotient map from pre-Lie to the associative operad, one gets a map from $G_{PL}$ to the composition group of formal power series without constant term. The image of $\Omega_q$ is then a $q$-logarithm.

On the other hand, looking at corollas only, one gets a map from $G_{PL}$ to the group of formal power series with constant term 1 for multiplication. The image of $\Omega_q$ is then the generating function of the $q$-Bernoulli numbers introduced by Carlitz. These numbers appear quite naturally here.

We recall in Appendix A the functorial definition of a group $G_\mathcal{P}$ from an augmented operad $\mathcal{P}$. On this subject, the reader may also consult [Chapoton 2002a; 2007/08; van der Laan 2003; Chapoton and Livernet 2007].

In Appendix B, we give, for concreteness, the first few terms of the rooted-trees series that we consider.

Many useful computations and checks have been done using MuPAD.

### 2. General setting

We will work over the field $\mathbb{Q}$ of rational numbers and over the field $\mathbb{Q}(q)$ of fractions in the indeterminate $q$.

We have tried to avoid using operads as much as possible, but this language is necessary to define the ambient groups, and we will need it at some points in this article. The reader may consult [Loday 2001; Chapoton 2007/08] as references. The symbol $\circ_i$ will denote the (single) composition at position $i$ in an operad and the symbols $♭$ and $♮$ will serve to note positions where composition is done.

**Pre-Lie algebras.** Recall (see for instance [Chapoton and Livernet 2001]) that a *pre-Lie algebra* is a vector space $V$ endowed with a bilinear map $\circ$ from $V \otimes V$ to $V$ satisfying the axiom

$$\quad (x \circ y) \circ z - x \circ (y \circ z) = (x \circ z) \circ y - x \circ (z \circ y).$$

This is sometimes called a *right pre-Lie algebra.*
The pre-Lie product \( \bigcirc \) defines a Lie bracket on \( V \) as:
\[
[x, y] = x \bigcirc y - y \bigcirc x.
\] (2)

One can easily check that the pre-Lie axiom (1) implies the Jacobi identity for the antisymmetric bracket \([ , ]\). The Lie algebra \((V, [ , ])\) will be called \( V_{\text{Lie}} \).

The pre-Lie product \( \bigcirc \) can also be considered as a right action \( \bigcirc \) of the associated Lie algebra \( V_{\text{Lie}} \) on the vector space \( V \). Indeed, one has
\[
(x \bigcirc y) \bigcirc z - (x \bigcirc z) \bigcirc y = x \bigcirc [y, z].
\] (3)

This should not be confused with the adjoint action of a Lie algebra on itself.

**Free pre-Lie algebras and rooted trees.** The free pre-Lie algebras have a simple description using rooted trees. Let us recall briefly this description and other properties. Details and proofs can be found in [Chapoton and Livernet 2001].

A rooted tree is a finite, connected and simply connected graph, together with a distinguished vertex called the root. We will picture rooted trees with their root at the bottom and orient (implicitly) the edges towards the root. There are two distinguished kinds of rooted trees: corollas, where every vertex other than the root is linked to the root by an edge; and linear trees, where at every vertex, there is at most one incoming edge. See Figure 4 on page 620 for examples. A forest of rooted trees is a finite graph whose connected components are rooted trees.

The free pre-Lie algebra \( PL(S) \) on a set \( S \) has a basis indexed by rooted trees decorated by \( S \), that is, rooted trees together with a map from their set of vertices to \( S \).

The pre-Lie product \( T \bigcirc T' \) of a tree \( T' \) on another one \( T \) is given by the sum of all possible trees obtained from the disjoint union of \( T \) and \( T' \) by adding an edge from the root of \( T' \) to one of the vertices of \( T \) (the root of the resulting tree is the root of \( T \)). An example is depicted in Figure 1.

In particular, we will denote by \( PL \) the free pre-Lie algebra on one generator. This is the graded vector space \( PL = \oplus_{n \geq 1} PL_n \) spanned by unlabeled rooted trees, where the degree of a tree \( T \) is the number \#\( T \) of its vertices. The pre-Lie product obviously preserves this grading.
Universal enveloping algebras of free pre-Lie algebras. The Lie algebras $\mathrm{PL}(S)_{\mathrm{Lie}}$ have the curious property that their universal enveloping algebras come naturally equipped with a basis, which depends on no choice and has nothing to do with a Poincaré–Birkhoff–Witt basis. Let us explain this in the case of $\mathrm{PL}_{\mathrm{Lie}}$.

Let $U(\mathrm{PL})$ be the universal enveloping algebra of the Lie algebra $\mathrm{PL}_{\mathrm{Lie}}$. We will denote by $\star$ the associative product in $U(\mathrm{PL})$. We will freely identify right $\mathrm{PL}_{\mathrm{Lie}}$-modules with right $U(\mathrm{PL})$-modules. The crucial point is the following result [Chapoton and Livernet 2001, Theorem 3.3].

**Theorem 2.1.** There exists a unique isomorphism $\psi$ of graded right $\mathrm{PL}_{\mathrm{Lie}}$-modules between the free right $U(\mathrm{PL})$-module on one generator $g$ of degree 1 and the $\mathrm{PL}_{\mathrm{Lie}}$-module $(\mathrm{PL}, \curvearrowleft)$ such that $\psi$ maps the generator $g$ to the unique rooted tree with one vertex.

This means that there is a commutative diagram as follows:

$$
\begin{array}{ccc}
Qg \otimes U(\mathrm{PL}) \otimes \mathrm{PL}_{\mathrm{Lie}} & \xrightarrow{\psi \otimes \text{Id}} & \mathrm{PL} \otimes \mathrm{PL}_{\mathrm{Lie}} \\
\downarrow \text{Id} \otimes \star & & \downarrow \curvearrowleft \\
Qg \otimes U(\mathrm{PL}) & \xrightarrow{\psi} & \mathrm{PL}
\end{array}
$$

As $Qg$ has dimension 1, the map $\psi$ can be considered as an isomorphism of vector spaces between $U(\mathrm{PL})$ and PL. One can therefore use $\psi$ and the canonical basis of PL (indexed by rooted trees) to get a canonical basis of the enveloping algebra $U(\mathrm{PL})$. It is more convenient to index this basis by forests of rooted trees as follows. The inverse image $\psi^{-1}(T)$ in $U(\mathrm{PL})$ of a tree $T$ in PL can be seen as an element of $U(\mathrm{PL})$. This element is defined to be the basis element corresponding to the forest $F$ obtained from $T$ by removal of its root. For example, one has $\psi(\bullet) = \circ$.

By using diagram (4) for the unit element 1 in $U(\mathrm{PL})$ (that is, the empty forest), one can show that the map from $\mathrm{PL}_{\mathrm{Lie}}$ to $U(\mathrm{PL})$ given by the universal property of the enveloping algebra corresponds to the inclusion of the set of rooted trees (as a
A rooted-trees $q$-series lifting a one-parameter family of Lie idempotents

Figure 3. Product of a forest and a tree in $U(PL)$.

basis of $PL$) in the set of forests (as a basis of $U(PL)$). Indeed, for a rooted tree $T$, the top horizontal arrow maps $g \otimes 1 \otimes T$ to $\bullet \otimes T$. The right vertical arrow maps this to $\bullet \curvearrowright T$. Then the inverse of $\psi$ removes the root, which just gives $T$ (seen as a forest with just one connected component). The image of the natural inclusion of $PL_{Lie}$ in $U(PL)$ is therefore the subspace spanned by rooted trees.

Note that one can use diagram (4) to compute the $\star$ product of a forest and a rooted tree in $U(PL)$, as a sum of forests (see Figure 3 for an example, compare with Figure 1). The usual spanning set of the universal enveloping algebra $U(PL)$ is the set of noncommutative monomials in rooted trees (for the $\star$ product). By induction on the length of the monomial, one can therefore map each such noncommutative monomial to a sum of forests. Examples are given in Figures 2 and 3.

In the basis of $U(PL)$ indexed by forests, there is a nice combinatorial description of the associative product $\star$. Let $F$ and $F'$ be forests in $U(PL)$. The product $F \star F'$ is the sum of all possible forests, obtained from the disjoint union of $F$ and $F'$ by the addition of some edges (possibly none), each of these new edges going from some root of $F'$ to some vertex of $F$. Indeed, one can easily check that this operation is associative and coincide with $\star$ on rooted trees, hence the result.

There is a canonical projection $\pi$ from $U(PL)$ to $PL$, defined using the canonical basis of $U(PL)$ by projection on the subspace spanned by rooted trees, annihilating the empty forest and all forests that are not trees.

Lemma 2.2. Let $F$ be a forest in $U(PL)$ and $T$ be a rooted tree in $PL$. Then one has $\pi (F \star T) = \pi (F) \curvearrowright T$.

Proof. If $F$ is not a tree, then each term of $F \star T$ is not a tree, therefore both sides vanish. If $F = \pi (F)$ is a tree, then $F \star T$ is the sum of $\pi (F) \curvearrowright T$ with the disjoint union of $F$ and $T$. Therefore $\pi (F \star T) = \pi (F) \curvearrowright T$. \qed

The reader can check this statement on the examples of Figures 2 and 3.

Lemma 2.3. For all $n \geq 1$, the maps $T \mapsto \bullet \curvearrowright T$ and $T \mapsto T \curvearrowright \bullet$ are injective from $PL_n$ to $PL_{n+1}$.

Proof. This is obvious for the first map, which is even an injection on the set of rooted trees. For the second map, this follows from the fact that enveloping algebras are domains, by restriction of the commutative diagram (4). \qed
**Group associated to the pre-Lie operad.** In the sequel, we will always work in the completed vector space $\widehat{PL} = \prod_{n \geq 1} PL_n$ and with its completed enveloping algebra $\widehat{U}(PL)$. All the results above are still true in this setting.

There is a group associated to each operad; see Appendix A and [Chapoton 2002a; 2007/08; van der Laan 2003; Chapoton and Livernet 2007]. We will need the group $G_{PL}$ associated to the pre-Lie operad. Its elements are the elements of $\widehat{PL}$ whose homogeneous component of degree 1 is $\bullet$. The product in $G_{PL}$ is defined using the composition of the pre-Lie operad and $\bullet$ is the unit in $G_{PL}$. This group is contained in the bigger monoid $\widehat{PL}$, on which it therefore acts on the right and on the left. The right action respects all the operations on $\widehat{PL}$ induced by the product $\circlearrowleft$, including the product and the action of $\widehat{U}(PL)$.

Let us now introduce a special element of $G_{PL}$ for later use. Let $\exp^* \in G_{PL}$ be

$$\exp^* = \bullet \circlearrowleft ((\exp(\bullet) - 1)/\bullet),$$  \hspace{1cm} (5)

where the rightmost factor is an element of $\widehat{U}(PL)$ defined using the formal power series $(\exp x - 1)/x$ and the $\star$ product.

The series $\exp^*$ is very classical, related to the flow of vector fields, and its coefficients are known as the Connes–Moscovici coefficients [Chapoton 2002a].

Consider the left action of $\exp^*$ on $\widehat{PL}$. Let $T$ be an element of $\widehat{PL}$. Then $\exp^*(T)$ in $\widehat{PL}$ is defined by

$$\exp^*(T) = \sum_{n \geq 1} \frac{1}{n!} ((T \circlearrowleft T \circlearrowleft \ldots) \circlearrowleft T),$$  \hspace{1cm} (6)

where there are $n$ copies of $T$ in the $n$-th term. As $\exp^*$ belongs to the group $G_{PL}$, the map $\exp^*$ defines a bijection from $\widehat{PL}$ to itself.

Let us now relate the usual exponential map $\exp$ to the map $\exp^*$.

Let $T$ be an element of $\widehat{PL}$. Let $\exp T$ be the exponential of $T$ in $\widehat{U}(PL)$ (which is defined by the usual series and using the $\star$ product). The map $\exp$ defines a bijection from $\widehat{PL}$ to the set of group-like elements of $\widehat{U}(PL)$.

Therefore, the composite map $\exp^* \circ \exp^{-1}$ is a bijection from the set of group-like elements in $\widehat{U}(PL)$ to $\widehat{PL}$. Let us show that this composite map is just a restriction of the canonical projection $\pi$.

**Proposition 2.4.** Let $T$ be an element of $\widehat{PL}$. One has $\pi(\exp T) = \exp^*(T)$.

**Proof.** Let $F$ be in $\widehat{U}(PL)$. From Lemma 2.2 above, one knows that $\pi(F \star T)$ is exactly $\pi(F) \circlearrowleft T$. This implies that

$$\pi(T^{*n}) = ((T \circlearrowleft T \ldots) \circlearrowleft T),$$ \hspace{1cm} (7)

for all $n \geq 1$, hence the result.  \hspace{1cm} $\Box$
3. The classical case

Let us start by recalling the definition of a classical element $\Omega$ of $\hat{\mathcal{P}} \mathcal{L}$ with rational coefficients. It seems to have first appeared in [Agračev and Gamkrelidze 1980], was later considered under the name of $\log^*$ in [Chapoton 2002a] and has been since studied in [Murua 2006; Wright and Zhao 2003; Ebrahimi-Fard and Manchon 2009; Calaque et al. 2008].

**Proposition 3.1.** There is a unique solution $\Omega$ in $\hat{\mathcal{P}} \mathcal{L}_Q$ to the equation

$$\bullet \ua \left( \frac{\Omega}{\exp \Omega - 1} \right) = \Omega, \quad (8)$$

where $\Omega/(\exp \Omega - 1)$ is in the completed enveloping algebra $\hat{\mathcal{U}}(\mathcal{P} \mathcal{L})$.

**Proof.** Let us write $\Omega = \sum_{n \geq 1} \Omega_n$ where each $\Omega_n$ is homogeneous of degree $n$.

Recall the Taylor expansion

$$\frac{x}{\exp x - 1} = \sum_{k \geq 0} \frac{B_k}{k!} x^k, \quad (9)$$

where the $B_k$ are the Bernoulli numbers.

Then the homogeneous component of degree $n$ of Equation (8) is

$$\Omega_n = \sum_{k \geq 0} \frac{B_k}{k!} \sum_{m_1 \geq 1, \ldots, m_k \geq 1} ((\bullet \ua \Omega_{m_k}) \ldots) \ua \Omega_{m_1}. \quad (10)$$

This gives a recursive definition of $\Omega_n$, which implies the existence and uniqueness of $\Omega$. \hfill \Box

**Remark.** One can use Equation (10) to compute $\Omega$ up to order $n$ in a $O(n^3)$ number of pre-Lie operations.

As the element $\Omega/(\exp \Omega - 1)$ is invertible in the completed enveloping algebra, Equation (8) is also equivalent to the following equation:

$$\Omega \ua \left( \frac{\exp \Omega - 1}{\Omega} \right) = \bullet. \quad (11)$$

One can interpret Equation (11) as follows.

**Proposition 3.2.** The series $\Omega$ is the inverse of $\exp^*$ in the group $\mathcal{G}_{\mathcal{P} \mathcal{L}}$.

**Proof.** By right action by the inverse $\Omega^{-1}$ of $\Omega$ in $\mathcal{G}_{\mathcal{P} \mathcal{L}}$ on (11), one shows that $\Omega^{-1}$ satisfies the same Equation (5) as $\exp^*$. \hfill \Box

There is another equation for $\Omega$. 

Proposition 3.3. The series $\Omega$ is the unique nonzero solution in $\hat{PL}_Q$ to the equation
\begin{equation}
\Omega \cap (\exp \Omega - 1) = \bullet \cap \Omega,
\end{equation}
where $\exp \Omega - 1$ is in the completed enveloping algebra $\hat{U}(PL)$.

Proof. First, by right action on (11) by $\Omega$, one can see that the unique solution $\Omega$ of (8) is indeed a solution of (12).

Let us now prove uniqueness of a nonzero solution. Let $\Omega$ be any solution of (12). Let us write $\Omega = \sum_{n \geq 1} \Omega_n$ where each $\Omega_n$ is homogeneous of degree $n$.

Then the homogeneous component of degree $n$ of Equation (12) is
\begin{equation}
\bullet \cap \Omega_{n-1} = \sum_{k \geq 1} \frac{1}{k!} \sum_{m_1 \geq 1, \ldots, m_k \geq 1, \ell \geq 1} ((\Omega_\ell \cap \Omega_{m_k}) \ldots) \cap \Omega_{m_1}.
\end{equation}

If $n = 2$, this implies that $\Omega_1$ is either 0 or $\bullet$.

Assume now that $\Omega_1$ is not zero. Let $d$ be the degree of the first nonzero homogeneous component $\Omega_d$ of $\Omega$. Assume that $d > 1$. Then Equation (13) in degree $d + 1$, together with Lemma 2.3, gives that $\Omega_d = 0$, a contradiction. Therefore necessarily, one has $d = 1$ and $\Omega_1 = \bullet$.

Let us look at the homogeneous component (13) in degree $n + 1 \geq 2$. The only terms involving $\Omega_n$ are $\bullet \cap \Omega_n$ in the left-hand side and $\Omega_1 \cap \Omega_n$, $\Omega_n \cap \Omega_1$ in the right hand-side. As $\Omega_1 = \bullet$, two of them cancel out and one gets a recursive expression of $\Omega_n \cap \bullet$ in terms of some $\Omega_j$ for $j < n$.

Using Lemma 2.3, this provides a recursive description of $\Omega$ (that may or may not possess a solution) and proves its uniqueness. \qed

The exponential of $\Omega$ has a simple shape.

Proposition 3.4. In the enveloping algebra $\hat{U}(PL)$, one has
\begin{equation}
\exp \Omega = \sum_{n \geq 0} \frac{1}{n!} \bullet \ldots \bullet,
\end{equation}
where, in the $n$-th term, the forest has $n$ nodes.

Proof. This is an equation for the exponential $\exp \Omega$ of the element $\Omega$ in the Lie algebra $\hat{PL}$. By Proposition 2.4, it is enough to prove that
\begin{equation}
\exp^*(\Omega) = \bullet,
\end{equation}
because the image by $\pi$ of the right side of (14) is $\bullet$.

But this amounts to saying that $\exp^*$ is the inverse of $\Omega$ in the group $G_{PL}$. This is none other than Proposition 3.2. \qed
A rooted-trees $q$-series lifting a one-parameter family of Lie idempotents

It follows that

$$\Omega \cap (\exp \Omega - 1) = \sum_{n \geq 2} \frac{1}{(n-1)!} \text{Cr}_n^\natural \circ_i \Omega,$$  \hspace{1cm} (16)

where $\text{Cr}_n^\natural$ is the corolla with $n-1$ leaves and root labeled by $\natural$; see Figure 4.

**Proposition 3.5.** The series $\Omega$ is the unique nonzero solution in $\hat{\mathcal{PL}}_\mathbb{Q}$ to the equation

$$\sum_{n \geq 2} \frac{1}{(n-1)!} \text{Cr}_n^\natural \circ_i \Omega = \bullet \cap \Omega,$$  \hspace{1cm} (17)

where $\sum_{n \geq 2} \frac{1}{(n-1)!} \text{Cr}_n^\natural$ is in $\hat{\mathcal{PL}}$.

*Proof.* This follows from (16) and Proposition 3.3. \qed

### 4. The quantum case

We will introduce now an element $\Omega_q$ in $\hat{\mathcal{PL}}$ with coefficients in $\mathbb{Q}(q)$. We will show later that this is a $q$-deformation of $\Omega$.

If $A = \sum_{n \geq 1} A_n$ is an element of $\hat{\mathcal{PL}}$, let $A[q]$ be the $q$-shift of $A$ defined by

$$A[q] = \sum_{n \geq 1} q^n A_n.$$  \hspace{1cm} (18)

**Proposition 4.1.** There exists a unique solution $\Omega_q$ in $\mathcal{PL}_\mathbb{Q}(q)$ to the equation

$$\Omega_q[q] \cap (\exp \Omega - 1) + \Omega_q[q] - \Omega_q = \bullet \cap \Omega_q + (q - 1) \bullet.$$  \hspace{1cm} (19)

Moreover, the series $\Omega_q$ has coefficients in the ring of fractions with poles only at roots of unity.

*Proof.* Write $\Omega_q = \sum_{n \geq 1} \Omega_{q,n}$ where each $\Omega_{q,n}$ is homogeneous of degree $n$. The homogeneous component of degree 1 of (19) implies that $\Omega_{q,1} = \bullet$.

Then for $n \geq 2$, the homogeneous component of degree $n$ of Equation (19) is

$$(q^n - 1)\Omega_{q,n}$$

$$= \bullet \cap \Omega_{q,n-1} - \sum_{k \geq 1} \frac{1}{k!} \sum_{m_1 \geq 1, \ldots, m_k \geq 1, \ell \geq 1} q^\ell ((\Omega_{q,\ell} \cap \Omega_{m_k}) \ldots) \cap \Omega_{m_1}. $$  \hspace{1cm} (20)

This provides an explicit recursion for $\Omega_{q,n}$ in terms of $\Omega_{q,j}$ and $\Omega_j$ for $j < n$. This gives existence and uniqueness and also implies that $\Omega_q$ has coefficients with poles only at roots of unity. \qed

On can reformulate the equation for $\Omega_q$. 
Figure 4. Rooted trees: $\text{Lnr}_5^b$, $\text{Crl}_6^\natural$ and $\text{Frk}_{4,5}^\natural = \text{Lnr}_5^b \circ \text{Crl}_6^\natural$.

**Proposition 4.2.** The series $\Omega_q$ is the unique solution in $\widehat{\mathcal{PL}}_{\Omega(q)}$ to the equation

$$
\sum_{n \geq 1} \frac{1}{(n-1)!} \text{Crl}_n^\natural \circ \bigoplus \Omega_q[q] = \bigoplus \Omega_q + (q-1) \bigoplus.
$$

(21)

**Proof.** This follows from (16) and Proposition 4.1. □

Let $\text{Frk}_{\ell,n}^\natural$ be the rooted tree with a linear trunk of $\ell$ vertices, a vertex $\natural$ on top of this trunk and a corolla with $n$ leaves on top of the vertex $\natural$, see Figure 4. We will call this a fork. One has $\text{Frk}_{\ell,n}^\natural = \text{Lnr}_\ell^b \circ \text{Crl}_n^\natural$.

**Proposition 4.3.** The series $\Omega_q$ is the unique solution in $\widehat{\mathcal{PL}}_{\Omega(q)}$ to the equation

$$
\Omega_q = \sum_{\ell \geq 0} \sum_{n \geq 0} \frac{(-1)^\ell}{n!} \text{Frk}_{\ell,n}^\natural \circ \bigoplus \Omega_q[q] + (1-q) \sum_{\ell \geq 1} (-1)^{\ell-1} \text{Lnr}_\ell.
$$

(22)

**Proof.** Let us compute the right-hand side of (22), using (21) for $\Omega_q$, written as

$$
\Omega_q + \bigoplus \bigoplus + (q-1) \bigoplus = \sum_{n \geq 1} \frac{1}{(n-1)!} \text{Crl}_n^\natural \circ \bigoplus \Omega_q[q].
$$

(23)

One gets

$$
\sum_{\ell \geq 1} (-1)^{\ell-1} \text{Lnr}_\ell \circ \bigoplus \Omega_q + (q-1) \bigoplus + (1-q) \sum_{\ell \geq 1} (-1)^{\ell-1} \text{Lnr}_\ell.
$$

(24)

As $\text{Lnr}_\ell \circ \bigoplus = \text{Lnr}_\ell$ and $\text{Lnr}_\ell \circ \bigoplus (\bigoplus \bigoplus) = \text{Lnr}_\ell+1 \circ \bigoplus \Omega_q$, the two rightmost terms cancels, and the sum simplifies to

$$
\sum_{\ell \geq 1} (-1)^{\ell-1} \text{Lnr}_\ell \circ \bigoplus \Omega_q - \sum_{\ell \geq 2} (-1)^{\ell-1} \text{Lnr}_\ell \circ \bigoplus \Omega_q,
$$

(25)

which is just $\Omega_q$. This proves that $\Omega_q$ does satisfy (22).

It is then easy to see that (22) has only one solution in $\widehat{\mathcal{PL}}_{\Omega(q)}$ by rewriting it as a recursion for the homogeneous components $\Omega_{q,n}$.
5. Image in the free dendriform algebra

We describe in this section the image of $\Omega_q$ by the usual morphism from the free pre-Lie algebra to the free dendriform algebra. We show that this image is related to a family of Lie idempotents in the descent algebras of the symmetric groups. One deduces from that a nice explicit formula, that will be used later to get arithmetic information on $\Omega_q$.

Dendriform algebra. Recall that a dendriform algebra [Loday 2001] is a vector space $V$ endowed with two bilinear maps $\succ$ and $\prec$ from $V \otimes V$ to $V$ satisfying the following axioms:

\begin{align}
  x \prec (y \prec z) + x \prec (y \succ z) &= (x \prec y) \prec z, 
  &\quad (26) \\
  x \succ (y \prec z) &= (x \succ y) \prec z, 
  &\quad (27) \\
  x \succ (y \succ z) &= (x \succ y) \succ z + (x \prec y) \succ z. 
  &\quad (28)
\end{align}

Any dendriform algebra has the structure of a pre-Lie algebra given by

\begin{equation}
  x \otimes y = y \succ x - x \prec y. 
\end{equation}

Any dendriform algebra has the structure of an associative algebra given by

\begin{equation}
  x * y = x \succ y + x \prec y. 
\end{equation}

Remark. Equation (27) means that one can safely forget some parentheses. Equations (26) and (28) can be rewritten as

\begin{align}
  x \prec (y * z) &= (x \prec y) \prec z, 
  &\quad (31) \\
  x \succ (y \succ z) &= (x * y) \succ z. 
  &\quad (32)
\end{align}

Let Dend($S$) be the free dendriform algebra over a set $S$. This has an explicit basis indexed by planar binary trees with vertices decorated by $S$. For an example of a planar binary tree, see Figure 5. In particular, the free dendriform algebra on one generator, denoted by Dend, has a basis indexed by planar binary trees. This is a graded vector space, the degree $#t$ of a planar binary tree $t$ being the number of its inner vertices.

There is a unique morphism $\varphi$ of pre-Lie algebras from PL to Dend that maps the rooted tree $\bullet$ to the planar binary tree $\Upsilon$. This extends uniquely to a continuous morphism $\varphi$ from $\hat{PL}$ to the completion $\hat{\text{Dend}}$ of Dend.

Remark. With some care, one can add a unit 1 to the free dendriform algebra Dend. Then $1 * x = 1 \succ x = x = x \prec 1 = x * 1$, but one has to pay attention to never write either $1 \prec x$ or $x \succ 1$. We will use this convention in the sequel.
There are two kinds of special planar binary trees: the left combs and the right combs. They can be defined as follows. Let $L = \sum_{n \geq 1} L_n$ be the unique solution in $\hat{\text{Dend}}$ to the equation

$$L = \U + L \rightarrows \U = (1 + L) \rightarrows \U,$$  \hfill (33)

and let $R = \sum_{n \geq 1} R_n$ be the unique solution in $\hat{\text{Dend}}$ to

$$R = \U + \U \leftarrows R = \U \leftarrows (1 + R).$$ \hfill (34)

Then $L_n$ is called the left comb with $n$ vertices and $R_n$ be the right comb with $n$ vertices.

If $A = \sum_{n \geq 1} A_n$ is an element of $\hat{\text{PL}}$ or $\hat{\text{Dend}}$, the suspension of $A$ is $\tilde{A} = \sum_{n \geq 1} (-1)^{n-1} A_n$.

**Proposition 5.1.** The inverse of $1 + R$ with respect to the $\ast$ product is $1 - \tilde{L}$.

**Proof.** One has $\tilde{L} = \U - \tilde{L} \rightarrows \U$. We compute

$$(1 - \tilde{L}) \ast (1 + R) = 1 + R - \tilde{L} \ast (1 + R).$$ \hfill (35)

By the definition of $\ast$ and the convention on the unit $1$, this is

$$1 + R - \tilde{L} \leftarrows (1 + R) - \tilde{L} \rightarrows R.$$ \hfill (36)

By (33), this becomes

$$1 + R - \U \leftarrows (1 + R) + \tilde{L} \rightarrows \U \leftarrows (1 + R) - \tilde{L} \rightarrows R.$$ \hfill (37)

The last two terms cancel by (34) and one gets

$$1 + R - \U \leftarrows (1 + R),$$ \hfill (38)

which is just 1, again by (34). \hfill \Box

**Equation for the dendriform image of $\Omega_q$.** Define a series $E = \sum_{n \geq 1} n L_n$ in $\hat{\text{Dend}}$. One can easily show that

$$E = L + E \rightarrows \U.$$ \hfill (39)

**Lemma 5.2.** The series $B^\flat = \varphi (\sum_{n \geq 1} \text{Ln}^\flat_n)$ satisfies

$$B^\flat = \U^\flat + B^\flat \rightarrows \U - \U \leftarrows B^\flat.$$ \hfill (40)

**Proof.** This comes from a similar equation in $\text{PL}$. Let $\text{Ln}^\flat = \sum_{n \geq 1} \text{Ln}^\flat_n$. Then

$$\text{Ln}^\flat = \bullet^\flat + \bullet \cap \text{Ln}^\flat,$$ \hfill (41)

as one can easily check. \hfill \Box

These relations can be taken as definitions of the elements $E$ and $B^\flat$ of $\hat{\text{Dend}}$. One can forget the marking $\flat$ in $B^\flat$ to define a series $B$. 
Proposition 5.3. The series \( B = \varphi\left(\sum_{n \geq 1} \ln r_n\right) \) satisfies
\[
E = (1 + L) * B. \tag{42}
\]

Proof. One has to show that \( E = (1 + L) * B \). It is enough to prove that \( (1 + L) * B \) does satisfy the defining relation (39) of \( E \).

One computes, using (40) for \( B \),
\[
(1 + L) * B = (1 + L) * (\bigvee B \bowtie \bigvee - \bigvee < B). \tag{43}
\]

Expanding the * product, this is
\[
(1 + L) > \bigvee + L < \bigvee + (1 + L) > (\bigvee - \bigvee < B) + L < (\bigvee - \bigvee < B). \tag{44}
\]

Using (33) and the dendriform axioms, this becomes
\[
L + L < \bigvee + ((1 + L) * B) > \bigvee - (1 + L) > \bigvee < B + L < (\bigvee - \bigvee < B). \tag{45}
\]

Using (33) again, one gets
\[
L + ((1 + L) * B) > \bigvee + L < (\bigvee - B + B > \bigvee - \bigvee < B). \tag{46}
\]

This simplifies, by (40) for \( B \), to
\[
L + ((1 + L) * B) > \bigvee, \tag{47}
\]

as expected. \qed

Lemma 5.4. The image of \( \sum_{n \geq 1} \frac{1}{(n-1)!} \text{Cr}_n \bigotimes \) by \( \varphi \) is
\[
(1 + R) > \bigvee \bigotimes \bigvee < (1 - \bar{L}). \tag{48}
\]

Proof. This was proved in [Ronco 2000; 2001; Chapoton 2002b]. \qed

Proposition 5.5. The image of \( \sum_{\ell \geq 0} \sum_{n \geq 0} \frac{(-1)^{\ell}}{n!} \text{Frk}_{\ell,n} \bigotimes \) by \( \varphi \) is
\[
(1 + R) * \bigvee \bigotimes (1 - \bar{L}), \tag{49}
\]

where \( \bigvee \bigotimes \) is the planar binary tree \( \bigvee \) with vertex labeled by \( \bigotimes \).

Proof. Let \( D = (1 + R) * \bigvee (1 - \bar{L}). \) Let us first show that
\[
D = (1 + R) > \bigvee \bigotimes (1 - \bar{L}) + \bigvee < D - D > \bigvee. \tag{50}
\]

Expanding the * product, one computes
\[
D = \left((1 + R) * \bigvee\bigotimes\right) < (1 - \bar{L}) - (1 + R) * \bigvee\bigotimes > \bar{L}. \tag{51}
\]

Then one gets, by expanding again,
\[
(1 + R) > \bigvee \bigotimes < (1 - \bar{L}) + (R < \bigvee\bigotimes) < (1 - \bar{L}) - (1 + R) * \bigvee\bigotimes > \bar{L}. \tag{52}
\]
Using the dendriform axioms, this is

\[(1 + R) \succ Y^z < (1 - L) + R < (Y^z * (1 - L)) - ((1 + R) * Y^z) > L. \] (53)

Then by (33) and (34), this can be rewritten

\[(1 + R) \succ Y^z < (1 - L) + (Y < (1 + R)) < (Y^z * (1 - L))
- ((1 + R) * Y^z) > ((1 - L) > Y). \] (54)

One gets, using the dendriform axioms,

\[(1 + R) \succ Y^z < (1 - L) + Y < ((1 + R) * Y^z * (1 - L))
- ((1 + R) * Y^z * (1 - L)) > Y. \] (55)

This proves Equation (50) for \(D\).

Let us show now that \(D' = (\sum_{\ell \geq 1} (-1)^{\ell-1} \varphi(Ln r^\ell) \sum_{n \geq 1} 1/(n-1)! \varphi(\text{Cr} l^z_n))\) does satisfy the same equation as \(D\).

By Lemma 5.4, one has

\[D' = \tilde{B}^\circ \circ ((1 + R) > Y^z < (1 - L)). \] (56)

By Lemma 5.2, one has \(\tilde{B}^\circ = Y^z - \tilde{B}^\circ \succ Y + Y < \tilde{B}^\circ\), hence

\[D' = (1 + R) > Y^z < (1 - L) + Y < D' - D > Y. \] (57)

By uniqueness of the solution \(D\) of (50), one has \(D = D'\), that is,

\[(1 + R) * Y^z *(1 - L) = (\sum_{\ell \geq 1} (-1)^{\ell-1} \varphi(Ln r^\ell) \sum_{n \geq 1} 1/(n-1)! \varphi(\text{Cr} l^z_n)). \] (58)

Therefore

\[(1 + R) * Y^z * (1 - L) = \varphi \left( \left( \sum_{\ell \geq 1} (-1)^{\ell-1} \varphi(Ln r^\ell) \sum_{n \geq 1} 1/(n-1!) \varphi(\text{Cr} l^z_n) \right) \right), \] (59)

which is exactly the expected image by \(\varphi\) of a sum over forks.

One can now deduce a useful functional equation for the image of \(\Omega_q\) by \(\varphi\), using only the associative product * of Dend.

**Proposition 5.6.** The series \(\varphi(\Omega_q)\) is the unique solution in \(\widehat{\text{Dend}}\) of

\[\varphi(\Omega_q) = (1 - L)^{-1} * \varphi(\Omega_q)[q] * (1 - L) + (1 - q) \sum_{\ell \geq 1} (-1)^{\ell-1} \varphi(Ln r^\ell). \] (60)
Proof. Let us start from (22). By Proposition 5.5, we know the image by $\varphi$ of the sum over forks. One gets
\[
\varphi(\Omega_q) = ((1 + R) \ast \gamma \ast (1 - L)) \circ_2 \varphi(\Omega_q)[q] + (1 - q) \sum_{\ell \geq 1} (-1)^{\ell - 1} \varphi(\text{Lnr}_\ell). \quad (61)
\]
Then one can use Proposition 5.1 to replace $1 + R$ by the inverse of $1 - L$.

Explicit formula. We will prove in this section that the image of $\Omega_q$ by $\varphi$ coincides (in some sense) with a known family of Lie idempotents, and has an explicit description using $q$-binomial coefficients, descents and major indices of planar binary trees. To obtain this description, we use a result on noncommutative symmetric functions. We refer to [Gelfand et al. 1995; Duchamp et al. 1997; Krob et al. 1997] for background on this subject. We will use the notation of this last article.

The algebra $\text{Sym}$ of noncommutative symmetric function is the free unital associative algebra on generators $S_1, S_2, \ldots$. It is a graded algebra (with $S_i$ of degree $i$), with a basis $(S_I)_I$ indexed by compositions. There is another basis $(R_I)_I$ obtained from the basis $(S_I)_I$ by Möbius inversion on compositions ordered by refinement. By convention, $S_0$ is the unit of $\text{Sym}$.

As $\text{Sym}$ is free, there is a unique morphism of associative algebras $\theta$ from $\text{Sym}$ to $\text{Dend}$ which maps $S_i$ to the left comb $L_i$ for each $i \geq 0$, with the convention that $L_0$ is the unit of $\text{Dend}$.

One can check that $\theta$ is the usual morphism from $\text{Sym}$ to $\text{Dend}$, considered for instance in [Hivert et al. 2005, Section 4.8] and [Loday and Ronco 1998].

In $\text{Sym}$, there are elements $\Psi_i$ for $i \geq 1$, uniquely defined by the conditions
\[
nS_n = \sum_{i=0}^{n-1} S_i \ast \Psi_{n-i}, \quad (62)
\]
for all $n \geq 1$.

Proposition 5.7. The image of $\Psi_i$ by $\theta$ is $\varphi(\text{Lnr}_i)$.

Proof. This is a corollary of Proposition 5.3. Indeed, one has
\[
1 + L = \sum_{n \geq 0} \theta(S_n) \quad \text{and} \quad E = \sum_{n \geq 1} n \theta(S_n). \quad (63)
\]
Therefore
\[
B = \sum_{n \geq 1} \theta(\Psi_n). \quad \Box
\]

The leaves of a planar binary tree with $n$ vertices are labeled from 0 to $n$ from left to right. The leaves with labels different from 0 and $n$ are called inner leaves. A descent in a planar binary tree $t$ is the label of an $\backslash$-oriented inner leaf. The descent set $D(t)$ of $t$ is the set of its descents.
The number of descents of a planar binary tree \( t \) will be denoted \( d(t) \). It satisfies \( 0 \leq d(t) \leq n - 1 \) for a tree \( t \) of degree \( n \).

The major index \( \text{maj}(t) \) of \( t \) is the sum of its descents. For example, Figure 5 displays a planar binary tree with descent set \( \{2, 4\} \) and major index \( 2 + 4 = 6 \).

Let us recall that the descent set \( D(I) \) corresponding to a composition \( I = (i_1, \ldots, i_k) \) of \( n \) is the set \( \{i_1, i_1 + i_2, \ldots, i_1 + \cdots + i_k\} \).

**Proposition 5.8.** The image by \( \theta \) of \( R_I \) is the sum

\[
\sum_{\# t = n, D(t) = D(I)} t
\]

of all planar binary trees with \( n \) vertices and descent set \( D(I) \).

**Proof.** This is a well-known property of the injection of Sym in Dend. \( \square \)

In [Krob et al. 1997], elements \( \Psi_n(A/(1 - q)) \), for \( n \geq 1 \), are defined by some “change of alphabet” applied to the elements \( \Psi_n \). According to the proof of [Krob et al. 1997, Theorem 6.11], they are characterized by

\[
\sum_{n \geq 1} \Psi_n \left( \frac{A}{1-q} \right) = \left( \sum_{n \geq 0} S_n \right)^{-1} \left( \sum_{n \geq 1} q^n \Psi_n \left( \frac{A}{1-q} \right) \right) \left( \sum_{n \geq 0} S_n \right) + \sum_{n \geq 1} \Psi_n. \tag{65}
\]

There is a classical isomorphism of vector spaces \( \alpha \) from Sym to the direct sum of all descent algebras of symmetric groups. By this morphism, each \( \Psi_n(A/(1-q)) \) is mapped, up to a multiplicative constant, to a Lie idempotent with coefficients in \( \mathbb{Q}(q) \) in the descent algebra of the \( n \)-th symmetric group.

We can now state the precise relation between \( \Omega_q \) and these Lie idempotents, or rather with the elements \( \Psi_n(A/(1-q)) \).

**Proposition 5.9.** The image of \((1-q)^{\psi(A/(1-q))}\) by \( \theta \) is \( \psi(\widehat{\Omega}_q) \).

**Proof.** Indeed, by Proposition 5.6, one has

\[
\sum_{n \geq 1} \phi(\widehat{\Omega}_q) = (1 + L)^{-1} \ast (\phi(\widehat{\Omega}_q)[q]) \ast (1 + L) + (1 - q) \sum_{n \geq 1} \phi(\text{Ln}r_n). \tag{66}
\]
Then using Proposition 5.7 and (65), one gets that \( \theta((1 - q)\Psi(A/(1 - q))) \) and \( \varphi(\Omega_q) \) satisfy the same equation, hence they are equal.

Let \( \Omega_{q,n} \) be the homogeneous component of degree \( n \) of \( \Omega_q \).

**Proposition 5.10.** One has

\[
\varphi(\Omega_{q,n}) = \frac{(-1)^{n-1}}{[n]_q} \sum_{\#I = n} (-1)^d I \binom{n-1}{d}^q q^{\text{maj}(I) - \binom{d+1}{2}} t. \tag{67}
\]

**Proof.** Theorem 6.11 of [Krob et al. 1997] says that the element \( (1 - q)\Psi_n \left( \frac{A}{1-q} \right) \) is

\[
\frac{1}{[n]_q} \sum_{|I| = n} (-1)^d I \binom{n-1}{d}^q q^{\text{maj}(I) - \binom{d+1}{2}} R_I. \tag{68}
\]

By Proposition 5.9, the image under \( \theta \) of this formula is \( (-1)^{n-1} \varphi(\Omega_{q,n}) \). By Proposition 5.8, this becomes the expected formula. \( \square \)

### 6. Arithmetic properties

In this section, we obtain some properties of the denominators in \( \Omega_q \) and consider what happens when \( q \) is specialized to 1, 0 and \( \infty \).

**The case \( q = 1 \).** First note that the morphism \( \varphi \) from \( \widehat{\text{PL}} \) to the completed free dendriform algebra \( \widehat{\text{Dend}} \) is defined over \( \mathbb{Q} \) and injective. Hence one can deduce results on \( \Omega_q \) from results on its image by \( \varphi \).

**Proposition 6.1.** The series \( \Omega_q \) is regular at \( q = 1 \) and \( \Omega_{q=1} = \Omega \).

**Proof.** By Proposition 5.10, the image \( \varphi(\Omega_q) \) is regular at \( q = 1 \), as \( q \)-binomial coefficients become usual binomial coefficients when \( q = 1 \). Therefore \( \Omega_q \) itself is regular at \( q = 1 \).

At \( q = 1 \), (19) becomes (12). By uniqueness in Proposition 3.3, the value of \( \Omega_q \) at \( q = 1 \) is \( \Omega \). \( \square \)

**Remark.** Knowing that \( \Omega_{q=1} = \Omega \), one can use (20) to compute simultaneously \( \Omega_q \) and \( \Omega \) up to order \( n \) in a \( O(n^3) \) number of pre-Lie operations.

There is a lot of cancellation in the coefficients of \( \Omega_q \), leading to a reduced complexity of the denominators. Note that the expected denominator of \( \Omega_{q,n} \) (from recursion (20)) is the product \( \prod_{d=2}^n (q^d - 1) \). Let \( \Phi_d \) be the \( d \)-th cyclotomic polynomial.

**Proposition 6.2.** The common denominator of the coefficients of the element \( \Omega_{q,n} \) divides the product \( \prod_{d=2}^n \Phi_d \).
Proof. For the image of $\Omega_q$ by $\varphi$, this follows from 5.10 and a simple property of the $q$-binomial coefficients: their only roots are simple roots at roots of unity, see [Guo and Zeng 2006, Proposition 2.2]. This implies the same result for $\Omega_q$. □

 Remark. The true denominator of each individual coefficient in $\Omega_q$ is often smaller than the complete product $\prod_{d=2}^{n} \Phi_d$, see for instance the first few terms in Appendix B.

The case $q = 0$. Let us consider now what happens when $q = 0$. Then $\Omega_0$ is well-defined, $\Omega_q[q]$ vanishes and (19) becomes

$$\Omega_0 = \bullet - \bullet \wedge \Omega_0. \quad (69)$$

It follows that $\Omega_0$ is the alternating sum of linear trees.

The case $q = \infty$. Let us now consider what happens when $q = \infty$. Let $\omega_{q,T}$ be the coefficient of the rooted tree $T$ in the expansion of $\Omega_q$. We define the valuation at $q = \infty$ as the smallest exponent in the formal Laurent expansion in powers of $q^{-1}$ of an element of $Q(q)$.

Proposition 6.3. The valuation of $\omega_{q,T}$ at $q = \infty$ is at least $\#T - 1$.

Proof. This will follow from the recursion (20). This is true in degree $n = 1$. Let us assume that $n \geq 2$. Then the valuation of $\bullet \wedge \Omega_{q,n-1}$ is at least $n - 2$ by induction and the valuation of each term of the rightmost sum in (20) is at least $-1$. Hence the valuation of $\Omega_{q,n}$ is at least $n - 1$. □

Hence there exists a limit $\Omega_{\infty}$ for $\Omega_q[q]/q$ when $q$ goes to $\infty$ and the limit of $\Omega_q/q$ is zero.

Equation (19), divided by $q$, becomes, at $q = \infty$,

$$\Omega_{\infty} \wedge \exp \Omega = \bullet. \quad (70)$$

By right action by $\exp(-\Omega)$, this is equivalent to

$$\Omega_{\infty} = \bullet \wedge \exp(-\Omega). \quad (71)$$

The element $\exp(-\Omega)$ is the inverse of $\exp \Omega$ in $\hat{U}(\text{PL})$. This has been computed in [Chapoton and Livernet 2007, Section 6.4]. More precisely, the inverse of $\sum_{n \geq 1} \frac{1}{(n-1)!} \text{Cr} \tau_n$ in the group of characters of the Connes–Kreimer Hopf algebra was shown there to be

$$\sum_T \frac{(-1)^{\#T - 1}}{\text{aut}(T)} T, \quad (72)$$

where $\text{aut}(T)$ is the cardinal of the automorphism group of the rooted tree $T$. But it is known [Chapoton and Livernet 2001] that this group of characters is isomorphic to the group of group-like elements in $\hat{U}(\text{PL})$. Going through the isomorphism, one gets the following result.
Proposition 6.4. The series $\Omega_{\infty}$ is given by

$$\Omega_{\infty} = \sum_T \frac{(-1)^{|T|-1}}{\text{aut}(T)} T.$$  

(73)

7. Morphisms and images

In this section, we consider several quotients of the free pre-Lie algebra $PL$ and the images of $\Omega_q$ in some of these quotients. The first two quotients come from quotients operads of the pre-Lie operad.

As shown in [Chapoton and Livernet 2001], the pre-Lie operad can be described in terms of labeled rooted trees. We recall here briefly (see the article just cited for details) the definition of the composition of two labeled rooted trees $T$ and $S$ on the vertex sets $I$ and $J$, respectively. Let $i \in I$; the composition of $S$ at the vertex $i$ of $T$ is given by

$$T \circ_i S = \sum_f T \circ^f_i S,$$  

(74)

where the sum runs over all maps $f$ from the set of incoming edges of the vertex $i$ of $T$ to the set of vertices of $S$, and $T \circ^f_i S$ can be described as follows: replace the vertex $i$ by the tree $S$, grafting back the subtrees of $T$ previously attached to $i$, according to the map $f$.

**Morphism to the free associative algebra.**

Proposition 7.1. The subspace of pre-Lie spanned by nonlinear labeled trees is an ideal. The quotient map $\kappa$ coincides with the usual map from pre-Lie to the associative operad $As$.

Proof. Using the description above of the composition map of the operad pre-Lie, it is clear that the composition of two labeled trees, at least one of which is nonlinear, is again nonlinear. The quotient operad, spanned by labeled linear trees, has dimension $n!$ in rank $n$. Its composition can be easily identified with the associative operad $As$. The quotient map is then checked on generators of pre-Lie to be the same as the usual map. □

Proposition 7.2. The group $G_{As}$ is isomorphic to the group of invertible formal power series in $x \mathbb{Q}[\![x]\!]$ for the composition product.

Proof. It is more convenient here to work at the monoid level with $\hat{As}$ and $x \mathbb{Q}[\![x]\!]$. The vector space $As(n)_{\hat{\mathbb{C}}_n}$ is one dimensional for all $n$, with a basis element $\theta_n$. By left linearity of both monoids, it is sufficient to check the product rule for $\theta_m$ and $f = \sum_{n \geq 1} f_n \theta_n$. One finds that

$$\theta_m \times f = \sum_{n_1, \ldots, n_m \geq 1} f_{n_1} \cdots f_{n_m} \theta_{n_1 + \cdots + n_m},$$  

(75)
which proves that the linear map defined by \( x^n \mapsto \theta_n \) is an isomorphism between the monoids \( \hat{A}_n \) and \( x \mathbb{Q}[x] \). The proposition follows by taking invertible elements.

The operad morphism \( \kappa \) induces a morphism of pre-Lie algebras from \( \mathcal{PL} \) to the free (nonunital) associative algebra \( \mathbb{Q}[x]_+ \) on one generator \( x \), sending \( \bullet \) to \( x \). This extends to a morphism from \( \mathcal{PL} \) to the algebra \( \mathbb{Q}[x]_+ \) of formal power series in \( x \) without constant term. This last morphism restricts to a group morphism from \( \mathcal{G}_{\text{pre-Lie}} \) to \( \mathcal{G}_{\text{As}} \). We will denote by \( \kappa \) all these morphisms.

One can see that \( \kappa \) sends the linear trees \( \text{Lnr}_n = (\bullet \odot \bullet) \ldots \odot \bullet \) to the monomials \( (xx) \ldots x = x^n \) and maps all other trees to 0.

From (8), one obtains that \( \kappa() \) satisfies

\[
\exp(\kappa(\Omega)) - 1 = x.
\] (76)

Therefore \( \kappa(\Omega) \) is the formal power series

\[
\log(1 + x) = \sum_{n \geq 1} \frac{(-1)^{n-1}}{n} x^n.
\] (77)

One then deduces from (19) that the image of \( \Omega_q \) is the \( q \)-logarithm defined by

\[
\log_q(x) = \sum_{n \geq 1} \frac{(-1)^{n-1}}{[n]_q} x^n,
\] (78)

which is the unique solution to the functional equation

\[
x \log_q(qx) = x \log_q(x) + (q - 1) x - \log_q(qx) + \log_q(x).
\] (79)

**Morphism to corollas and point-wise multiplication.** Let the depth of a rooted tree be the maximum number of vertices in a chain of adjacent vertices between the root and a leaf. Corollas are then the rooted trees of depth at most 2.

**Proposition 7.3.** The subspace of pre-Lie spanned by labeled noncorollas is an ideal.

**Proof.** Using the description above of the composition of pre-Lie, one shows that the depth of the composition of two labeled trees is greater or equal than the maximum of the depths of these labeled trees. Therefore, if one of the labeled trees has depth greater or equal to three, so does the composition.

Let us denote by \( \text{Mu} \) the quotient operad and by \( \lambda \) the quotient map from pre-Lie to \( \text{Mu} \). One can give a simple description of \( \text{Mu} \). It has dimension \( n \) in rank \( n \) with basis given by the image of the labeled corollas with \( n \) nodes. Let us call \( \mu_i^n \) the image of the corolla with \( n \) nodes and with root labeled by \( i \) for \( i = 1, \ldots, n \).
Then $\mu^1_1$ is the unit of $\text{Mu}$ and the composition is given by

$$
\begin{align*}
\mu^n_i \circ \mu_j^\ell &= \mu^{n+\ell-1}_{i+j-1},\quad &\text{for } h \neq i \text{ and } \ell \geq 2, \\
\mu^n_i \circ h \mu_j^\ell &= 0
\end{align*}
$$

Let $G_1$ be the group of formal power series of the form $1 + x \mathbb{Q}[x]$ for the point-wise multiplication product and $G_2$ be the multiplicative group $\mathbb{Q}^*$. There is an action of $G_2$ on $G_1$ by substitution: $\lambda \cdot f(x) = f(\lambda x)$.

From the description of $\text{Mu}$ above, one deduces that

**Proposition 7.4.** The group $G_{\text{Mu}}$ is isomorphic to $G_2 \ltimes G_1$.

**Proof.** The vector space $\text{Mu}(n)$ is one-dimensional for all $n$, with basis given by the image of the corolla with $n$ nodes. Let us denote this basis element by $\nu_{n-1}$. Any element of $G_{\text{Mu}}$ can be uniquely written as the product $\lambda (\sum_{m \geq 0} f_m v_m)$ of $\lambda \in \mathbb{Q}^*$ and $f = \sum_{m \geq 0} f_m v_m$ with $f_0 = 1$. Let us compute the product of $\lambda f = \lambda (\sum_{m \geq 0} f_m v_m)$ and $\theta g = \theta (\sum_{n \geq 0} g_n v_n)$ with the conventions $f_0 = 1$ and $g_0 = 1$. One finds that

$$
\lambda f \times \theta g = \sum_{m \geq 0} \sum_{n \geq 0} \lambda f_m \theta^n (\theta g_n) v_{n+m} = \lambda \theta \sum_{m \geq 0} \sum_{n \geq 0} \theta^m f_m g_n v_{n+m}.
$$

One defines a map from $G_{\text{Mu}}$ to $G_2 \ltimes G_1$ by $\lambda (\sum_{m} f_m v_m) \mapsto (\lambda, f(x))$ with $f(x) = \sum_{m} f_m x^m$. The product in $G_2 \ltimes G_1$ is given by

$$
(\lambda, f(x))(\theta, g(x)) = (\lambda \theta, f(\theta x)g(x)).
$$

Hence the map is an isomorphism. $\square$

The quotient map $\lambda$ induces a morphism of pre-Lie algebras from $PL$ to the following pre-Lie algebra. Let us identify the image of the corolla $\mathcal{C}r_{1,n+1}$ with $n$ leaves to $x^n$ for all $n \geq 0$. In particular, the tree $\bullet$ is mapped to 1. The underlying vector space is therefore identified with $\mathbb{Q}[x]$ and the quotient pre-Lie product is

$$
x^p \triangledown x^q = \begin{cases} x^{p+q} & \text{if } q = 0, \\ 0 & \text{else}. \end{cases}
$$

One can show (using the description of the quotient $\triangledown$ product given above) that the right action by $\lambda(\Omega)$ is given by the product by $x$. Therefore, the right action of the image of $\exp(\lambda(\Omega)) - 1$ is just given by the product by $\exp x - 1$. One sees as well that the right action by $\lambda(\Omega_q)$ is also given by the product by $x$.

Then one deduces from Proposition 3.3 that the image $\lambda(\Omega)$ is the generating function $x/(\exp x - 1)$ for the Bernoulli numbers.

Next, from (19), one gets that the image $F_q(x)$ of $\Omega_q$ satisfies the equation

$$
(\exp x - 1)[q F_q(qx)] = x + q - 1 - q F_q(qx) + F_q(x).
$$
This functional equation is known (see for instance [Satoh 1989]) to describe the generating function

\[ F = \sum_{n \geq 0} \beta_n(q) \frac{x^n}{n!}, \tag{85} \]

where \( \beta_q(n) \) are the \( q \)-Bernoulli numbers of [Carlitz 1948; 1954; 1958]. Therefore the coefficients of the corollas in \( \Omega_q \) are the \( q \)-Bernoulli numbers of Carlitz. One may wonder whether it is possible to describe directly the coefficient of each rooted tree in \( \Omega_q \).

**Morphism to a pre-Lie algebra of vector fields.** There exists an interesting morphism from PL to a pre-Lie algebra of vector fields. We describe it here only as a side remark, as the image of \( \Omega_q \) seems to have no special property.

Consider the vector space \( V = \mathbb{Q}[x]_+ \), endowed with the following pre-Lie product:

\[ f \cdot g = xf \partial_x g. \tag{86} \]

Then there is a unique morphism from PL to \( V \) sending \( \bullet \) to \( x \).

This map has the following nice property: the coefficient of \( x^n \) in the image of a series \( A \) is the sum of the coefficients of the trees in the homogeneous component \( A_n \) of \( A \). The proof is just a check that this sum-of-coefficients map defines a morphism of pre-Lie algebra from PL to \( V \).

**Appendix A. A group associated to an augmented operad**

We briefly recall here the definition for each augmented operad of a group of formal power series. This can also be found in [Chapoton 2002a; 2007/08; van der Laan 2003; Chapoton and Livernet 2007]. We use in this section the definition of the notion operad by a multiple composition map \( \gamma \), which is equivalent (using the unit) to the definition using the single compositions \( \circ_i \) that we have used elsewhere in the article.

Let \( \mathcal{P} \) be an operad in the category \( \text{Vect}_\mathbb{Q} \) of vector spaces over \( \mathbb{Q} \) and assume that \( \mathcal{P}(0) = \{0\} \) and that \( \mathcal{P}(1) = \mathbb{Q}e \) where \( e \) is the unit of \( \mathcal{P} \). Such an operad is called **augmented**.

Let \( F\mathcal{P} = \bigoplus_n \mathcal{P}(n)_{\mathbb{Q}_e} \) be the direct sum of the coinvariant spaces, which can be identified with the underlying vector space of the free \( \mathcal{P} \)-algebra on one generator, and \( \widehat{\mathcal{P}} = \prod_n \mathcal{P}(n)_{\mathbb{Q}_e} \) be its completion.

Let \( x = \sum_m x_m, y = \sum_n y_n \) be two elements of \( \widehat{\mathcal{P}} \). Choose any representatives \( \tilde{x}_m \) of \( x_m \) (resp. \( \tilde{y}_n \) of \( y_n \)) in the operad \( \mathcal{P} \). Then one can check that the following formula defines a product on \( \widehat{\mathcal{P}} \):

\[ x \times y = \sum_{m \geq 1} \sum_{n_1, \ldots, n_m \geq 1} (\gamma(\tilde{x}_m, \tilde{y}_{n_1}, \ldots, \tilde{y}_{n_m})), \tag{A.1} \]
where $\langle \rangle$ is the quotient map to the coinvariants and $\gamma$ is the (multiple) composition map of the operad $\mathcal{P}$.

**Proposition A.1.** The product $\times$ defines the structure of an associative monoid on the vector space $\hat{\mathcal{P}}$. Furthermore, this product is $\mathbb{Q}$-linear on its left argument.

**Proof.** We first prove associativity. On the one hand,

$$(x \times y) \times z = \sum_m \sum_{p_1, \ldots, p_m} \langle \gamma((x \times y)_m, \bar{z}_{p_1}, \ldots, \bar{z}_{p_m}) \rangle. \quad (A.2)$$

On the other hand,

$$x \times (y \times z) = \sum_m \sum_{n_1, \ldots, n_m} \sum_{p_1, \ldots, p_{n_1} + \ldots + n_m} \langle \gamma(\gamma(\bar{x}_m, \bar{y}_{n_1}, \ldots, \bar{y}_{n_m}), \bar{z}_{p_1}, \ldots, \bar{z}_{p_{n_1} + \ldots + n_m}) \rangle. \quad (A.3)$$

Using then the "associativity" of the operad, one gets the associativity of $\times$. It is easy to check that the image of the unit $e$ of the operad $\mathcal{P}$ is a two-sided unit for the $\times$ product. The left $\mathbb{Q}$-linearity is clear from the formula (A.1). $\square$

**Proposition A.2.** An element $y$ of $\hat{\mathcal{P}}$ is invertible for $\times$ if and only if the first component $y_1$ of $y$ is nonzero.

**Proof.** The direct implication is trivial. The reverse one is proved by a very standard recursive argument. $\square$

Let us call $G_{\mathcal{P}}$ the set of invertible elements of $\hat{\mathcal{P}}$ for the $\times$ product.

**Proposition A.3.** $G$ is a functor from the category of augmented operads to the category of groups.

**Proof.** The functoriality follows from inspection of the definitions of $\hat{\mathcal{P}}$ and $\times$. $\square$

In fact, one can see $G_{\mathcal{P}}$ as the group of $\mathbb{Q}$-points of a proalgebraic group. The Lie algebra of this proalgebraic group is given by the usual linearization process on the tangent space $\hat{\mathcal{P}}$, resulting in the formula

$$[x, y] = \sum_{m \geq 1} \sum_{n \geq 1} \langle \bar{x}_m \circ \bar{y}_n - \bar{y}_n \circ \bar{x}_m \rangle, \quad (A.4)$$
where

\[ \tilde{x}_m \circ \tilde{y}_n = \sum_{i=1}^{m} \gamma(\tilde{x}_m, e, \ldots, e, \tilde{y}_n, e, \ldots, e). \tag{A.5} \]

The graded Lie algebra structure on \( F_H \) defined by the same formulas has already appeared in the work of Kapranov and Manin on the category of right modules over an operad [Kapranov and Manin 2001, Theorem 1.7.3].

**Appendix B. First terms of some expansions**

\[ \Omega = - \frac{1}{2} \odot + \frac{1}{3} \odot + \frac{1}{12} \odot - \frac{1}{4} \odot - \frac{1}{12} \odot \]

\[ + \frac{1}{5} \odot + \frac{3}{40} \odot + \frac{1}{10} \odot + \frac{1}{180} \odot + \frac{1}{60} \odot \]

\[ + \frac{1}{20} \odot + \frac{1}{120} \odot - \frac{1}{120} \odot - \frac{1}{720} \odot + \cdots \tag{B.1} \]

For \( n \geq 1 \), let \( \Phi_n \) be the \( n \)-th cyclotomic polynomial.

\[ \Omega_q = - \frac{1}{2 \Phi_2} \odot + \frac{1}{3 \Phi_3} \odot + \frac{q}{2 \Phi_2 \Phi_3} \odot \]

\[ - \frac{1}{\Phi_2 \Phi_4} \odot + \frac{q}{2 \Phi_3 \Phi_4} \odot - \frac{q^2}{\Phi_2 \Phi_3 \Phi_4} \odot - \frac{q(q-1)}{6 \Phi_2 \Phi_3 \Phi_4} \odot \]

\[ + \frac{1}{\Phi_5} \odot + \frac{q(1+q+q^2)}{2 \Phi_2 \Phi_4 \Phi_5} \odot + \frac{q^2}{\Phi_4 \Phi_5} \odot + \frac{q(q^3+q^2-1)}{6 \Phi_2 \Phi_3 \Phi_4 \Phi_5} \odot \]

\[ + \frac{q^4}{2 \Phi_3 \Phi_4 \Phi_5} \odot + \frac{q^3}{2 \Phi_2 \Phi_3 \Phi_4 \Phi_5} \odot + \frac{q^2(q^3+q^2-1)}{2 \Phi_2 \Phi_3 \Phi_4 \Phi_5} \odot \]

\[ + \frac{q^2(q^3-q-1)}{2 \Phi_2 \Phi_3 \Phi_4 \Phi_5} \odot + \frac{q(q^4-q^3-2q^2-q+1)}{24 \Phi_2 \Phi_3 \Phi_4 \Phi_5} \odot + \cdots \tag{B.2} \]

\[ \Omega_\infty = - \odot + \frac{1}{2} \odot - \frac{1}{2} \odot - \frac{1}{6} \odot + \]

\[ \frac{1}{2} \odot + \frac{1}{2} \odot + \frac{1}{6} \odot + \frac{1}{2} \odot + \frac{1}{2} \odot + \frac{1}{24} \odot + \cdots \tag{B.3} \]

\[ \Omega_0 = \odot + \odot - \odot + \cdots \tag{B.4} \]
A rooted-trees q-series lifting a one-parameter family of Lie idempotents
