Principal $W$-algebras for $\text{GL}(m|n)$

Jonathan Brown, Jonathan Brundan and Simon M. Goodwin
Principal $W$-algebras for $\text{GL}(m|n)$

Jonathan Brown, Jonathan Brundan and Simon M. Goodwin

We consider the (finite) $W$-algebra $W_{m|n}$ attached to the principal nilpotent orbit in the general linear Lie superalgebra $\mathfrak{gl}_{m|n}(\mathbb{C})$. Our main result gives an explicit description of $W_{m|n}$ as a certain truncation of a shifted version of the Yangian $Y(\mathfrak{gl}_{1|1})$. We also show that $W_{m|n}$ admits a triangular decomposition and construct its irreducible representations.

1. Introduction

A (finite) $W$-algebra is a certain filtered deformation of the Slodowy slice to a nilpotent orbit in a complex semisimple Lie algebra $\mathfrak{g}$. Although the terminology is more recent, the construction has its origins in the classic work of Kostant [1978]. In particular, Kostant showed that the principal $W$-algebra—the one associated to the principal nilpotent orbit in $\mathfrak{g}$—is isomorphic to the center of the universal enveloping algebra $U(\mathfrak{g})$. In the last few years, there has been some substantial progress in understanding $W$-algebras for other nilpotent orbits thanks to works of Premet, Losev and others; see [Losev 2011] for a survey. The story is most complete (also easiest) for $\mathfrak{sl}_n(\mathbb{C})$. In this case, the $W$-algebras are closely related to shifted Yangians; see [Brundan and Kleshchev 2006].

Analogues of $W$-algebras have also been defined for Lie superalgebras; see, for example, the work of De Sole and Kac [2006, §5.2] (where they are defined in terms of BRST cohomology) or the more recent paper of Zhao [2012] (which focuses mainly on the queer Lie superalgebra $\mathfrak{q}_n(\mathbb{C})$). In this article, we consider the easiest of all the “super” situations: the principal $W$-algebra $W_{m|n}$ for the general linear Lie superalgebra $\mathfrak{gl}_{m|n}(\mathbb{C})$. Our main result gives an explicit isomorphism between $W_{m|n}$ and a certain truncation of a shifted subalgebra of the Yangian $Y(\mathfrak{gl}_{1|1})$; see Theorem 4.5. Its proof is very similar to the proof of the analogous result for nilpotent matrices of Jordan type $(m, n)$ in $\mathfrak{gl}_{m+n}(\mathbb{C})$ from [Brundan and Kleshchev 2006].

Brown and Goodwin are supported by EPSRC grant number EP/G020809/1. Brundan is supported by NSF grant number DMS-1161094.

MSC2010: primary 17B10; secondary 17B37.

Keywords: $W$-algebras, Lie superalgebras.
The (super)algebra $W_{m|n}$ turns out to be quite close to being supercommutative. More precisely, we show that it admits a triangular decomposition

$$W_{m|n} = W_{m|n}^- W_{m|n}^0 W_{m|n}^+$$

in which $W_{m|n}^-$ and $W_{m|n}^+$ are exterior algebras of dimension $2^\min(m,n)$ and $W_{m|n}^0$ is a symmetric algebra of rank $m + n$; see Theorem 6.1. This implies that all the irreducible $W_{m|n}$-modules are finite-dimensional; see Theorem 7.2. We show further that they all arise as certain tensor products of irreducible $\mathfrak{gl}_{1|1}(\mathbb{C})$- and $\mathfrak{gl}_1(\mathbb{C})$-modules; see Theorem 8.4. In particular, all irreducible $W_{m|n}$-modules are of dimension dividing $2^\min(m,n)$. A closely related assertion is that all irreducible highest-weight representations of $Y(\mathfrak{gl}_{1|1})$ are tensor products of evaluation modules; this is similar to a well-known phenomenon for $Y(\mathfrak{gl}_2)$ going back to Tarasov 1985.

Some related results about $W_{m|n}$ have been obtained independently by Poletaeva and Serganova 2013. In fact, the connection between $W_{m|n}$ and the Yangian $Y(\mathfrak{gl}_{1|1})$ was foreseen long ago by Briot and Ragoucy 2003, who also looked at certain nonprincipal nilpotent orbits, which they assert are connected to higher-rank super Yangians although we do not understand their approach. It should be possible to combine the methods of this article with those of Brundan and Kleshchev 2006 to establish such a connection for all nilpotent orbits in $\mathfrak{gl}_{m|n}(\mathbb{C})$. However, this is not trivial and will require some new presentations for the higher-rank super Yangians adapted to arbitrary parity sequences; the ones in Gow 2007; Peng 2011 are not sufficient as they only apply to the standard parity sequence.

By analogy with the results of Kostant 1978, our expectation is that $W_{m|n}$ will play a distinguished role in the representation theory of $\mathfrak{gl}_{m|n}(\mathbb{C})$. In a forthcoming article by Brown et al., we will investigate the Whittaker coinvariants functor $H_0$, a certain exact functor from the analogue of category $\mathcal{O}$ for $\mathfrak{gl}_{m|n}(\mathbb{C})$ to the category of finite-dimensional $W_{m|n}$-modules. We view this as a replacement for the functor $\mathbb{V}$ of Soergel 1990; see also Backelin 1997. We will show that $H_0$ sends irreducible modules in $\mathcal{O}$ to irreducible $W_{m|n}$-modules or 0 and that all irreducible $W_{m|n}$-modules occur in this way; this should be compared with the analogous result for parabolic category $\mathcal{O}$ for $\mathfrak{gl}_{m+n}(\mathbb{C})$ obtained in Brundan and Kleshchev 2008, Theorem E. We will also use properties of $H_0$ to prove that the center of $W_{m|n}$ is isomorphic to the center of the universal enveloping superalgebra of $\mathfrak{gl}_{m|n}(\mathbb{C})$.

**Notation.** We denote the parity of a homogeneous vector $x$ in a $\mathbb{Z}/2$-graded vector space by $|x| \in \{0, \bar{1}\}$. A superalgebra means a $\mathbb{Z}/2$-graded algebra over $\mathbb{C}$. For homogeneous $x$ and $y$ in an associative superalgebra $A = A_0 \oplus A_1$, their supercommutator is $[x, y] := xy - (-1)^{|x||y|}yx$. We say that $A$ is supercommutative if $[x, y] = 0$ for all homogeneous $x, y \in A$. Also for homogeneous $x_1, \ldots, x_n \in A$, an ordered supermonomial in $x_1, \ldots, x_n$ means a monomial of the form $x_1^{i_1} \cdots x_n^{i_n}$ for $i_1, \ldots, i_n \geq 0$ such that $i_j \leq 1$ if $x_j$ is odd.
2. Shifted Yangians

Recall that \( \mathfrak{gl}_{m|n}(\mathbb{C}) \) is the Lie superalgebra of all \((m + n) \times (m + n)\) complex matrices under the supercommutator with \( \mathbb{Z}/2 \)-grading defined so that the matrix unit \( e_{i,j} \) is even if \( 1 \leq i, j \leq m \) or \( m + 1 \leq i, j \leq m + n \) and \( e_{i,j} \) is odd otherwise. We denote its universal enveloping superalgebra \( U(\mathfrak{gl}_{m|n}) \); it has basis given by all ordered supermonomials in the matrix units.

The Yangian \( Y(\mathfrak{gl}_{m|n}) \) was introduced originally by Nazarov [1991]; see also [Gow 2007]. We only need here the special case of \( Y = Y(\mathfrak{gl}_{1|1}) \). For its definition, we fix a choice of parity sequence

\[(|1|, |2|) \in \mathbb{Z}/2 \times \mathbb{Z}/2 \] (2-1)

with \(|1| \neq |2|\). All subsequent notation in the remainder of the article depends implicitly on this choice. Then we define \( Y \) to be the associative superalgebra on generators \( \{t_{i,j}^{(r)} \mid 1 \leq i, j \leq 2, \ r > 0\} \), with \( t_{i,j}^{(r)} \) of parity \(|i| + |j|\), subject to the relations

\[
[t_{i,j}^{(r)}, t_{p,q}^{(s)}] = (-1)^{|i||j|+|i||p|+|j||p|} \sum_{a=0}^{\min(r,s)-1} (t_{p,j}^{(a)} t_{i,q}^{(r+s-1-a)} - t_{p,j}^{(r+s-1-a)} t_{i,q}^{(a)}),
\]

adopting the convention that \( t_{i,j}^{(0)} = \delta_{i,j} \) (Kronecker delta).

**Remark 2.1.** In the literature, one typically only finds results about \( Y(\mathfrak{gl}_{1|1}) \) proved for the definition coming from the parity sequence \((|1|, |2|) = (\bar{0}, \bar{1})\). To aid in translating between this and the other possibility, we note that the map \( t_{i,j}^{(r)} \mapsto (-1)^r t_{i,j}^{(r)} \) defines an isomorphism between the realizations of \( Y(\mathfrak{gl}_{1|1}) \) arising from the two choices of parity sequence.

As in [Nazarov 1991], we introduce the generating function

\[ t_{i,j}(u) := \sum_{r \geq 0} t_{i,j}^{(r)} u^{-r} \in Y[[u^{-1}]]. \]

Then \( Y \) is a Hopf superalgebra with comultiplication \( \Delta \) and counit \( \varepsilon \) given in terms of generating functions by

\[
\Delta(t_{i,j}(u)) = \sum_{h=1}^{2} t_{i,h}(u) \otimes t_{h,j}(u), \quad (2-2)
\]

\[
\varepsilon(t_{i,j}(u)) = \delta_{i,j}. \quad (2-3)
\]

There are also algebra homomorphisms

\[
in : U(\mathfrak{gl}_{1|1}) \to Y, \quad e_{i,j} \mapsto (-1)^{|i|} t_{i,j}^{(1)}, \quad (2-4)
\]

\[
ev : Y \to U(\mathfrak{gl}_{1|1}), \quad t_{i,j}^{(r)} \mapsto \delta_{r,0} \delta_{i,j} + (-1)^{|i|} \delta_{r,1} e_{i,j}. \quad (2-5)
\]
The composite \( \ev \circ \im \) is the identity; hence, \( \im \) is injective and \( \ev \) is surjective. We call \( \ev \) the \textit{evaluation homomorphism}.

We need another set of generators for \( Y \) called \textit{Drinfeld generators}. To define these, we consider the Gauss factorization \( T(u) = F(u)D(u)E(u) \) of the matrix

\[
T(u) := \begin{pmatrix} t_{1,1}(u) & t_{1,2}(u) \\ t_{2,1}(u) & t_{2,2}(u) \end{pmatrix}.
\]

This defines power series \( d_i(u), e(u), f(u) \in Y[[u^{-1}]] \) such that

\[
D(u) = \begin{pmatrix} d_1(u) & 0 \\ 0 & d_2(u) \end{pmatrix}, \quad E(u) = \begin{pmatrix} 1 & e(u) \\ 0 & 1 \end{pmatrix}, \quad F(u) = \begin{pmatrix} 1 & 0 \\ f(u) & 1 \end{pmatrix}.
\]

Thus, we have that

\[
d_1(u) = t_{1,1}(u), \quad d_2(u) = t_{2,2}(u) - t_{2,1}(u)t_{1,1}(u)^{-1}t_{1,2}(u), \quad (2-6)
\]

\[
e(u) = t_{1,1}(u)^{-1}t_{1,2}(u), \quad f(u) = t_{2,1}(u)t_{1,1}(u)^{-1}. \quad (2-7)
\]

Equivalently,

\[
t_{1,1}(u) = d_1(u), \quad t_{2,2}(u) = d_2(u) + f(u)d_1(u)e(u), \quad (2-8)
\]

\[
t_{1,2}(u) = d_1(u)e(u), \quad t_{2,1}(u) = f(u)d_1(u). \quad (2-9)
\]

The Drinfeld generators are the elements \( d_i^{(r)}, e^{(r)} \) and \( f^{(r)} \) of \( Y \) defined from the expansions

\[
d_i(u) = \sum_{r \geq 0} d_i^{(r)} u^{-r}, \quad e(u) = \sum_{r \geq 1} e^{(r)} u^{-r} \quad \text{and} \quad f(u) = \sum_{r \geq 1} f^{(r)} u^{-r}.
\]

Also define \( \tilde{d}_i^{(r)} \in Y \) from the identity \( \tilde{d}_i(u) = \sum_{r \geq 0} \tilde{d}_i^{(r)} u^{-r} := d_i(u)^{-1} \).

\textbf{Theorem 2.2 [Gow 2007, Theorem 3].} The superalgebra \( Y \) is generated by the even elements \( \{d_i^{(r)} \mid i = 1, 2, \ r > 0\} \) and odd elements \( \{e^{(r)}, f^{(r)} \mid r > 0\} \) subject only to the following relations:

\[
[d_i^{(r)}, d_j^{(s)}] = 0, \quad [e^{(r)}, f^{(s)}] = (-1)^{|i|} \sum_{a=0}^{r+s-1} \tilde{d}_1^{(a)} d_2^{(r+s-1-a)},
\]

\[
[e^{(r)}, e^{(s)}] = 0, \quad [d_i^{(r)}, e^{(s)}] = (-1)^{|i|} \sum_{a=0}^{r-1} d_i^{(a)} e^{(r+s-1-a)},
\]

\[
[f^{(r)}, f^{(s)}] = 0, \quad [d_i^{(r)}, f^{(s)}] = -(-1)^{|i|} \sum_{a=0}^{r-1} f^{(r+s-1-a)} d_i^{(a)}.
\]

Here \( d_i^{(0)} = 1 \) and \( \tilde{d}_i^{(r)} \) is defined recursively from \( \sum_{a=0}^{r} \tilde{d}_i^{(a)} d_i^{(r-a)} = \delta_{r,0} \).

\textbf{Remark 2.3.} By [Gow 2007, Theorem 4], the coefficients \( \{e^{(r)} \mid r > 0\} \) of the power series

\[
c(u) = \sum_{r \geq 0} c^{(r)} u^{-r} := \tilde{d}_1(u)d_2(u)
\]

(2-10)
generate the center of $Y$. Moreover, $[e^{(r)}, f^{(s)}] = (-1)^{|i||r|} c^{(r+s-1)}$, so these supercommutators are central.

**Remark 2.4.** Using the relations in Theorem 2.2, one can check that $Y$ admits an algebra automorphism

$$\zeta : Y \rightarrow Y, \quad d_1^{(r)} \mapsto \tilde{d}_2^{(r)}, \quad d_2^{(r)} \mapsto \tilde{d}_1^{(r)}, \quad e^{(r)} \mapsto -f^{(r)}, \quad f^{(r)} \mapsto -e^{(r)}. \quad (2-11)$$

By [Gow 2007, Proposition 4.3], this satisfies

$$\Delta \circ \zeta = P \circ (\zeta \otimes \zeta) \circ \Delta, \quad (2-12)$$

where $P(x \otimes y) = (-1)^{|x||y|} y \otimes x$.

**Proposition 2.5.** The comultiplication $\Delta$ is given on Drinfeld generators by the following:

$$\Delta(d_1(u)) = d_1(u) \otimes d_1(u) + d_1(u)e(u) \otimes f(u)d_1(u),$$

$$\Delta(\tilde{d}_1(u)) = \sum_{n \geq 0} (-1)^{[n/2]} e(u)^n \tilde{d}_1(u) \otimes \tilde{d}_1(u)f(u)^n,$$

$$\Delta(d_2(u)) = \sum_{n \geq 0} (-1)^{[n/2]} d_2(u)e(u)^n \otimes f(u)^{n-1}d_2(u),$$

$$\Delta(\tilde{d}_2(u)) = \tilde{d}_2(u) \otimes \tilde{d}_2(u) - e(u)\tilde{d}_2(u) \otimes \tilde{d}_2(u)f(u),$$

$$\Delta(e(u)) = 1 \otimes e(u) - \sum_{n \geq 1} (-1)^{[n/2]} e(u)^n \otimes \tilde{d}_1(u)f(u)^{n-1}d_2(u),$$

$$\Delta(f(u)) = f(u) \otimes 1 - \sum_{n \geq 1} (-1)^{[n/2]} d_2(u)e(u)^{n-1}\tilde{d}_1(u) \otimes f(u)^n.$$

**Proof.** Check the formulae for $d_1(u)$, $\tilde{d}_1(u)$ and $e(u)$ directly using (2-2), (2-6) and (2-7). The other formulae then follow using (2-12). \hfill \Box

Here is the *PBW theorem* for $Y$.

**Theorem 2.6** [Gow 2007, Theorem 1]. Order the set $\{t_{i,j}^{(r)} \mid 1 \leq i, j \leq 2, \ r > 0\}$ in some way. The ordered supermonomials in these generators give a basis for $Y$.

There are two important filtrations on $Y$. First we have the *Kazhdan filtration*, which is defined by declaring that the generator $t_{i,j}^{(r)}$ is in degree $r$, i.e., the filtered degree-$r$ part $F_rY$ of $Y$ with respect to the Kazhdan filtration is the span of all monomials of the form $t_{i_1,j_1}^{(r_1)} \cdots t_{i_n,j_n}^{(r_n)}$ such that $r_1 + \cdots + r_n \leq r$. The defining relations imply that the associated graded superalgebra $\text{gr}Y$ is supercommutative. Let $gl_{1|1}[x]$ denote the current Lie superalgebra $gl_{1|1}(\mathbb{C}) \otimes \mathbb{C} \mathbb{C}[x]$ with basis $\{e_{i,j}x^r \mid 1 \leq i, j \leq 2, \ r \geq 0\}$. Then Theorem 2.6 implies that $\text{gr}Y$ can be identified with the symmetric superalgebra $S(gl_{1|1}[x])$ of the vector superspace $gl_{1|1}[x]$ so that $\text{gr}_r t_{i,j}^{(r)} = (-1)^{|i|} e_{i,j}x^{r-1}$. 

The other filtration on $Y$, which we call the Lie filtration, is defined similarly by declaring that $t_{i,j}(r)$ is in degree $r - 1$. In this case, we denote the filtered degree-$r$ part of $Y$ by $F'_r Y$ and the associated graded superalgebra by $\text{gr}' Y$. By Theorem 2.6 and the defining relations once again, $\text{gr}' Y$ can be identified with the universal enveloping superalgebra $U(\mathfrak{gl}_{1|1}[x])$ so that $\text{gr}'_{r-1} t_{i,j}(r) = (-1)^{|i|} e_{i,j} x^{r-1}$. The Drinfeld generators $d_{i}^{(r)}$, $e^{(r)}$ and $f^{(r)}$ all lie in $F'_{r-1} Y$, and we have that

$$\text{gr}'_{r-1} d_{i}^{(r)} = \text{gr}'_{r-1} t_{i,i}^{(r)}, \quad \text{gr}'_{r-1} e^{(r)} = \text{gr}'_{r-1} t_{1,2}^{(r)}, \quad \text{gr}'_{r-1} f^{(r)} = \text{gr}'_{r-1} t_{2,1}^{(r)}.$$

(The situation for the Kazhdan filtration is more complicated: although $d_{i}^{(r)}$, $e^{(r)}$ and $f^{(r)}$ do all lie in $F_r Y$, their images in $\text{gr}_r Y$ are not in general equal to the images of $t_{i,i}^{(r)}$, $t_{1,2}^{(r)}$ or $t_{2,1}^{(r)}$, but they can expressed in terms of them via (2-6) and (2-7).) Combining the preceding discussion of the Lie filtration with Theorem 2.6, we obtain the following basis for $Y$ in terms of Drinfeld generators. (One can also deduce this by working with the Kazhdan filtration and using (2-6)–(2-9).)

**Corollary 2.7.** Order the set $\{d_{i}^{(r)} | i = 1, 2, \ r > 0\} \cup \{e^{(r)}, f^{(r)} | \ r > 0\}$ in some way. The ordered supermonomials in these generators give a basis for $Y$.

Now we are ready to introduce the shifted Yangians for $\mathfrak{gl}_{1|1}(\mathbb{C})$. This parallels the definition of shifted Yangians in the purely even case from [Brundan and Kleshchev 2006, §2]. Let $\sigma = (s_{i,j})_{1 \leq i, j \leq 2}$ be a $2 \times 2$ matrix of nonnegative integers with $s_{1,1} = s_{2,2} = 0$. We refer to such a matrix as a shift matrix. Let $Y_\sigma$ be the superalgebra with even generators $\{d_{i}^{(r)} | i = 1, 2, \ r > 0\}$ and odd generators $\{e^{(r)} | \ r > s_{1,2}\} \cup \{f^{(r)} | \ r > s_{2,1}\}$ subject to all of the relations from Theorem 2.2 that make sense, bearing in mind that we no longer have available the generators $e^{(r)}$ for $0 < r \leq s_{1,2}$ or $f^{(r)}$ for $0 < r \leq s_{2,1}$. Clearly there is a homomorphism $Y_\sigma \to Y$ that sends the generators of $Y_\sigma$ to the generators with the same name in $Y$.

**Theorem 2.8.** Order the set

$$\{d_{i}^{(r)} | i = 1, 2, \ r > 0\} \cup \{e^{(r)} | \ r > s_{1,2}\} \cup \{f^{(r)} | \ r > s_{2,1}\}$$

in some way. The ordered supermonomials in these generators give a basis for $Y_\sigma$. In particular, the homomorphism $Y_\sigma \to Y$ is injective.

**Proof.** It is easy to see from the defining relations that the monomials span, and their images in $Y$ are linearly independent by Corollary 2.7. □

From now on, we will identify $Y_\sigma$ with a subalgebra of $Y$ via the injective homomorphism $Y_\sigma \hookrightarrow Y$. The Kazhdan and Lie filtrations on $Y$ induce filtrations on $Y_\sigma$ such that $\text{gr} Y_\sigma \subseteq \text{gr} Y$ and $\text{gr}' Y_\sigma \subseteq \text{gr}' Y$. Let $\mathfrak{gl}_{1|1}[x]$ be the Lie subalgebra of $\mathfrak{gl}_{1|1}[x]$ spanned by the vectors $e_{i,j} x^r$ for $1 \leq i, j \leq 2$ and $r \geq s_{i,j}$. Then we have that $\text{gr} Y_\sigma = S(\mathfrak{gl}_{1|1}[x])$ and $\text{gr}' Y_\sigma = U(\mathfrak{gl}_{1|1}[x])$. 
**Remark 2.9.** For another shift matrix $\sigma' = (s_{i,j}')_{1 \leq i, j \leq 2}$ with $s_{2,1}' + s_{1,2}' = s_{2,1} + s_{1,2}$, there is an isomorphism

$$\iota : Y_\sigma \to Y_{\sigma'}, \quad d_i^{(r)} \mapsto d_i^{(r)}, \quad e^{(r)} \mapsto e^{(s_{1,2} - s_{2,1} + r)}, \quad f^{(r)} \mapsto f^{(s_{2,1}' - s_{2,1} + r)}.$$  

This follows from the defining relations. Thus, up to isomorphism, $Y_\sigma$ depends only on the integer $s_{2,1} + s_{1,2} \geq 0$, not on $\sigma$ itself. Beware though that the isomorphism $\iota$ does not respect the Kazhdan or Lie filtrations.

For $\sigma \neq 0$, $Y_\sigma$ is not a Hopf subalgebra of $Y$. However, there are some useful comultiplication-like homomorphisms between different shifted Yangians. To start with, let $\sigma^{\text{up}}$ and $\sigma^{\text{lo}}$ be the upper and lower triangular shift matrices obtained from $\sigma$ by setting $s_{2,1}$ and $s_{1,2}$, respectively, equal to 0. Then, by Proposition 2.5, the restriction of the comultiplication $\Delta$ on $Y$ gives a homomorphism

$$\Delta : Y_{\sigma} \to Y_{\sigma^{\text{lo}}} \otimes Y_{\sigma^{\text{up}}}.$$  

The remaining comultiplication-like homomorphisms involve the universal enveloping algebra $U(\mathfrak{gl}_1) = \mathbb{C}[e_1, 1]$. Assuming that $s_{1,2} > 0$, let $\sigma_+$ be the shift matrix obtained from $\sigma$ by subtracting 1 from the entry $s_{1,2}$. Then the relations imply that there is a well-defined algebra homomorphism

$$\Delta_+ : Y_\sigma \to Y_{\sigma_+} \otimes U(\mathfrak{gl}_1),$$

$$d_1^{(r)} \mapsto d_1^{(r)} \otimes 1, \quad d_2^{(r)} \mapsto d_2^{(r)} \otimes 1 + (-1)^{2|r|}d_2^{(r-1)} \otimes e_1, \quad e^{(r)} \mapsto e^{(r)} \otimes 1 + (-1)^{2|r|}e^{(r-1)} \otimes e_1,$$

$$f^{(r)} \mapsto f^{(r)} \otimes 1.$$  

Finally, assuming that $s_{2,1} > 0$, let $\sigma_-$ be the shift matrix obtained from $\sigma$ by subtracting 1 from $s_{2,1}$. Then there is an algebra homomorphism

$$\Delta_- : Y_\sigma \to U(\mathfrak{gl}_1) \otimes Y_{\sigma_-},$$

$$d_1^{(r)} \mapsto 1 \otimes d_1^{(r)}, \quad d_2^{(r)} \mapsto 1 \otimes d_2^{(r)} + (-1)^{2|r|}e_1 \otimes d_2^{(r-1)}, \quad f^{(r)} \mapsto 1 \otimes f^{(r)} + (-1)^{2|r|}e_1 \otimes f^{(r-1)}, \quad e^{(r)} \mapsto 1 \otimes e^{(r)}.$$  

If $s_{1,2} > 0$, we denote $(\sigma^{\text{up}})_+ = (\sigma_+)^{\text{up}}$ by $\sigma_+^{\text{up}}$. If $s_{2,1} > 0$, we denote $(\sigma^{\text{lo}})_- = (\sigma_-)^{\text{lo}}$ by $\sigma_-^{\text{lo}}$. If both $s_{1,2} > 0$ and $s_{2,1} > 0$, we denote $(\sigma_+)_- = (\sigma_-)_+$ by $\sigma_{\pm}$.

**Lemma 2.10.** Assuming that $s_{1,2} > 0$ in the first diagram, $s_{2,1} > 0$ in the second diagram and both $s_{1,2} > 0$ and $s_{2,1} > 0$ in the final diagram, the following commute:

$$Y_\sigma \xrightarrow{\Delta_+} Y_{\sigma_+} \otimes U(\mathfrak{gl}_1) \xrightarrow{\Delta \otimes \text{id}} Y_{\sigma^{\text{lo}}} \otimes Y_{\sigma^{\text{up}}} \otimes U(\mathfrak{gl}_1)$$

$$Y_{\sigma^{\text{lo}}} \otimes Y_{\sigma^{\text{up}}} \xrightarrow{\text{id} \otimes \Delta_+} Y_{\sigma^{\text{lo}}} \otimes Y_{\sigma^{\text{up}}} \otimes U(\mathfrak{gl}_1)$$

where $\Delta$ is the comultiplication and $\text{id}$ is the identity map.
Proof. Check on Drinfeld generators using (2-15) and (2-16) and Proposition 2.5. □

Remark 2.11. Writing \( \varepsilon : U(\mathfrak{gl}_1) \to \mathbb{C} \) for the counit, the maps \((\text{id} \otimes \varepsilon) \circ \Delta_+ \) and \((\varepsilon \otimes \text{id}) \circ \Delta_- \) are the natural inclusions \( Y_\sigma \to Y_{\sigma+} \) and \( Y_\sigma \to Y_{\sigma-} \), respectively. Hence, the maps \( \sigma^+ \) and \( \sigma^- \) are injective.

3. Truncation

Let \( \sigma = (s_{i,j})_{1 \leq i,j \leq 2} \) be a shift matrix. Suppose also that we are given an integer \( l \geq s_{2,1} + s_{1,2} \), and set

\[
   k := l - s_{2,1} - s_{1,2} \geq 0.
\]

In view of Lemma 2.10, we can iterate \( \Delta_+ \) a total of \( s_{1,2} \) times, \( \Delta_- \) a total of \( s_{2,1} \) times and \( \Delta \) a total of \( k - 1 \) times in any order that makes sense (when \( k = 0 \), this means we apply the counit \( \varepsilon \) once at the very end) to obtain a well-defined homomorphism

\[
   \Delta^l_\sigma : Y_\sigma \to U(\mathfrak{gl}_1)^{\otimes s_{2,1}} \otimes Y^{\otimes k} \otimes U(\mathfrak{gl}_1)^{\otimes s_{1,2}}.
\]

For example, if

\[
   \sigma = \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix},
\]

then

\[
   \Delta_3^\sigma = (\text{id} \otimes \varepsilon \otimes \text{id} \otimes \text{id}) \circ (\Delta_- \otimes \text{id} \otimes \text{id}) \circ (\Delta_+ \otimes \text{id}) \circ \Delta_+, \\
   \Delta_4^\sigma = (\text{id} \otimes \Delta_+ \otimes \text{id}) \circ (\Delta_- \otimes \text{id}) \circ \Delta_+ = (\text{id} \otimes \Delta_+ \otimes \text{id}) \circ (\text{id} \otimes \Delta_+) \circ \Delta_-, \\
   \Delta_5^\sigma = (\Delta_- \otimes \text{id} \otimes \text{id} \otimes \text{id}) \circ (\text{id} \otimes \Delta_+ \otimes \text{id}) \circ (\text{id} \otimes \Delta_+) \circ \Delta \\
   = (\text{id} \otimes \Delta \otimes \text{id} \otimes \text{id}) \circ (\Delta_- \otimes \text{id} \otimes \text{id}) \circ (\text{id} \otimes \Delta_+) \circ \Delta_+.
\]

Let

\[
   U^l_\sigma := U(\mathfrak{gl}_1)^{\otimes s_{2,1}} \otimes U(\mathfrak{gl}_1|_{11})^{\otimes k} \otimes U(\mathfrak{gl}_1)^{\otimes s_{1,2}},
\]
viewed as a superalgebra using the usual sign convention. Recalling \((2-5)\), we obtain a homomorphism
\[
ev^l_\sigma := (\id^{\otimes s_{2,1}} \otimes \ev^k \otimes \id^{\otimes s_{1,2}}) \circ \Delta^l_\sigma : Y_\sigma \rightarrow U^l_\sigma.
\] (3-2)

Let
\[
Y^l_\sigma := \ev^l_\sigma(Y_\sigma) \subseteq U^l_\sigma.
\] (3-3)

This is the shifted Yangian of level \(l\).

In the special case that \(\sigma = 0\), we denote \(\ev^l_\sigma, Y^l_\sigma \) and \(U^l_\sigma\) simply by \(\ev^l, Y^l \) and \(U^l\), respectively, so that \(Y^l = \ev^l(Y) \subseteq U^l\). We call \(Y^l\) the Yangian of level \(l\). Writing \(\overline{e}_{i,j}^{[c]} := (-1)^{|i|} 1^{\otimes (c-1)} \otimes e_{i,j} \otimes 1^{\otimes (l-c)}\), we have simply that
\[
\ev^l(t_{i,j}^{(r)}) = \sum_{1 < c_1 < \ldots < c_r \leq l} \sum_{1 \leq h_1, \ldots, h_{r-1} \leq 2} \overline{e}_{i,h_1}^{[c_1]} e_{h_1,h_2}^{[c_2]} \cdots e_{h_{r-1},j}^{[c_r]}
\] (3-4)

for any \(1 \leq i, j \leq 2\) and \(r \geq 0\). In particular, \(\ev^l(t_{i,j}^{(r)}) = 0\) for \(r > l\). Gow [2007, proof of Theorem 1] shows that the kernel of \(\ev^l : Y \rightarrow Y^l\) is generated by \(\{t_{i,j}^{(r)} \mid 1 \leq i, j \leq 2, \ r > l\}\) and, moreover, the images of the ordered supermonomials in the remaining elements \(\{t_{i,j}^{(r)} \mid 1 \leq i, j \leq 2, \ 0 < r \leq l\}\) give a basis for \(Y^l\).

(Actually, she proves this for all \(Y(\sl_1)\) and not just \(Y(\sl_{1|1})\).) The goal in this section is to prove analogues of these statements for \(Y_\sigma\) with \(\sigma \neq 0\).

Let \(I^l_\sigma\) be the two-sided ideal of \(Y_\sigma\) generated by the elements \(d_1^{(r)}\) for \(r > k\).

**Lemma 3.1.** \(I^l_\sigma \subseteq \ker \ev^l_\sigma\).

**Proof.** We need to show that \(\ev^l_\sigma(d_1^{(r)}) = 0\) for all \(r > k\). We calculate this by first applying all the maps \(\Delta_+ \) and \(\Delta_-\) to deduce that
\[
\ev^l_\sigma(d_1^{(r)}) = 1^{\otimes s_{2,1}} \otimes \ev^k(d_1^{(r)}) \otimes 1^{\otimes s_{1,2}}.
\]
Since \(d_1^{(r)} = t^{(r)}_{1,1}\), it is then clear from (3-4) that \(\ev^k(d_1^{(r)}) = 0\) for \(r > k\). \(\square\)

**Proposition 3.2.** The ideal \(I^l_\sigma\) contains all of the following elements:
\[
\sum_{s_{1,2} < a \leq r} d_1^{(r-a)} e^{(a)} \quad \text{for } r > s_{1,2} + k,
\] (3-5)
\[
\sum_{s_{2,1} < b \leq r} f^{(b)} d_1^{(r-b)} \quad \text{for } r > s_{2,1} + k,
\] (3-6)
\[
d_2^{(r)} + \sum_{s_{1,2} < a \atop s_{2,1} < b \atop a+b \leq r} f^{(b)} d_1^{(r-a-b)} e^{(a)} \quad \text{for } r > l.
\] (3-7)

**Proof.** Consider the algebra \(Y_\sigma[[u^{-1}]]\) of formal Laurent series in the variable \(u^{-1}\) with coefficients in \(Y_\sigma\). For any such formal Laurent series \(p = \sum_{r \leq N} p_r u^r\), we
write \([p] \geq 0\) for its polynomial part \(\sum_{r=0}^{N} p_r u^r\). Also write \(\equiv\) for congruence modulo \(Y_\sigma[u] + u^{-1} I_\sigma [[u^{-1}]]\), so \(p \equiv 0\) means that the \(u^r\)-coefficients of \(p\) lie in \(I_\sigma\) for all \(r < 0\). Note that if \(p \equiv 0\), \(q \in Y_\sigma[u]\), then \(pq \equiv 0\). In this notation, we have by definition of \(I_\sigma\) that \(u^k d_1(u) \equiv 0\). Introduce the power series

\[
e_\sigma(u) := \sum_{r > s_{1,2}} e^{(r)} u^{-r}, \quad f_\sigma(u) := \sum_{r > s_{2,1}} f^{(r)} u^{-r}.
\]

The proposition is equivalent to the following assertions:

\[
u^{s_{1,2}+k} d_1(u) e_\sigma(u) \equiv 0, \quad (3-8)
\]

\[
u^{s_{2,1}+k} f_\sigma(u) d_1(u) \equiv 0, \quad (3-9)
\]

\[
u^l (d_2(u) + f_\sigma(u) d_1(u) e_\sigma(u)) \equiv 0. \quad (3-10)
\]

For the first two, we use the identities

\[
(-1)^{|l|} [d_1(u), e^{(s_{1,2}+1)}] = u^{s_{1,2}} d_1(u) e_\sigma(u), \quad (3-11)
\]

\[
(-1)^{|l|} [f^{(s_{2,1}+1)}, d_1(u)] = u^{s_{2,1}} f_\sigma(u) d_1(u). \quad (3-12)
\]

These are easily checked by considering the \(u^{-r}\)-coefficients on each side and using the relations in Theorem 2.2. Assertions (3-8) and (3-9) follow from (3-11) and (3-12) on multiplying by \(u^k\) as \(u^k d_1(u) \equiv 0\). For the final assertion (3-10), recall the elements \(c^{(r)}\) from (2-10). Let \(c_\sigma(u) := \sum_{r > s_{2,1}+s_{1,2}} c^{(r)} u^{-r}\). Another routine check using the relations shows that

\[
(-1)^{|l|} [f^{(s_{2,1}+1)}, e_\sigma(u)] = u^{s_{2,1}} c_\sigma(u). \quad (3-13)
\]

Using (3-8), (3-12) and (3-13), we deduce that

\[
0 \equiv (-1)^{|l|} u^{s_{1,2}+k} [f^{(s_{2,1}+1)}, d_1(u) e_\sigma(u)]
\]

\[
= u^{s_{1,2}+k} d_1(u) (-1)^{|l|} [f^{(s_{2,1}+1)}, e_\sigma(u)] + u^{s_{1,2}+k} (-1)^{|l|} [f^{(s_{2,1}+1)}, d_1(u)] e_\sigma(u)
\]

\[
= u^l d_1(u) c_\sigma(u) + u^l f_\sigma(u) d_1(u) e_\sigma(u).
\]

To complete the proof of (3-10), it remains to observe that

\[
u^{s_{2,1}+s_{1,2}} c_\sigma(u) = u^{s_{2,1}+s_{1,2}} \tilde{d}_1(u) d_2(u) - [u^{s_{2,1}+s_{1,2}} \tilde{d}_1(u) d_2(u)] \geq 0;
\]

hence, \(u^l d_1(u) c_\sigma(u) \equiv u^l d_2(u)\).

For the rest of the section, we fix some total ordering on the set

\[
\Omega := \{d_1^{(r)} \mid 0 < r \leq k\} \cup \{d_2^{(r)} \mid 0 < r \leq l\}
\]

\[
\cup \{e^{(r)} \mid s_{1,2} < r \leq s_{1,2} + k\} \cup \{f^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k\}. \quad (3-14)
\]

**Lemma 3.3.** The quotient algebra \(Y_\sigma / I_\sigma^l\) is spanned by the images of the ordered supermonomials in the elements of \(\Omega\).
**Proof.** The Kazhdan filtration on \( Y_\sigma \) induces a filtration on \( Y_\sigma / I^{l}_\sigma \) with respect to which \( \text{gr}(Y_\sigma / I^{l}_\sigma) \) is a graded quotient of \( \text{gr} Y_\sigma \). We already know that \( \text{gr} Y_\sigma \) is supercommutative, so \( \text{gr}(Y_\sigma / I^{l}_\sigma) \) is too. Let \( d^{(r)}_i := \text{gr}_r (d^{(r)}_i + I^{l}_\sigma) \), \( \varepsilon^{(r)} := \text{gr}_r (e^{(r)} + I^{l}_\sigma) \) and \( f^{(r)} := \text{gr}_r (f^{(r)} + I^{l}_\sigma) \).

To prove the lemma, it is enough to show that \( \text{gr}(Y_\sigma / I^{l}_\sigma) \) is generated by

\[
\{ d^{(r)}_1 | 0 < r \leq k \} \cup \{ d^{(r)}_2 | 0 < r \leq l \} \cup \{ \varepsilon^{(r)} | s_{1,2} < r \leq s_{1,2} + k \} \cup \{ f^{(r)} | s_{2,1} < r \leq s_{2,1} + k \}.
\]

This follows because \( d^{(r)}_1 = 0 \) for \( r > k \), and each of the elements \( d^{(r)}_2 \) for \( r > l \), \( \varepsilon^{(r)} \) for \( r > s_{1,2} + k \) and \( f^{(r)} \) for \( r > s_{2,1} + k \) can be expressed as polynomials in generators of strictly smaller degrees by Proposition 3.2.

**Lemma 3.4.** The image under \( \text{ev}^l_\sigma \) of the ordered supermonomials in the elements of \( \Omega \) are linearly independent in \( Y^{l}_\sigma \).

**Proof.** Consider the standard filtration on \( U^{l}_\sigma \) generated by declaring that all the elements of the form \( 1 \otimes \cdots \otimes 1 \otimes x \otimes 1 \otimes \cdots \otimes 1 \) for \( x \in \mathfrak{gl}_1 \) or \( \mathfrak{gl}_{|\mathfrak{l}|} \) are in degree 1. It induces a filtration on \( Y^{l}_\sigma \) so that \( \text{gr} Y^{l}_\sigma \) is a graded subalgebra of \( \text{gr} U^{l}_\sigma \). Note that \( \text{gr} U^{l}_\sigma \) is supercommutative, so the subalgebra \( \text{gr} Y^{l}_\sigma \) is too. Each of the elements \( \text{ev}^l_\sigma (d^{(r)}_i) \), \( \text{ev}^l_\sigma (e^{(r)}) \) and \( \text{ev}^l_\sigma (f^{(r)}) \) are in filtered degree \( r \) by the definition of \( \text{ev}^l_\sigma \). Let \( d^{(r)}_i := \text{gr}_r (\text{ev}^l_\sigma (d^{(r)}_i)) \), \( \varepsilon^{(r)} := \text{gr}_r (\text{ev}^l_\sigma (e^{(r)})) \) and \( f^{(r)} := \text{gr}_r (\text{ev}^l_\sigma (f^{(r)})) \).

Let \( M \) be the set of ordered supermonomials in

\[
\{ d^{(r)}_1 | 0 < r \leq k \} \cup \{ d^{(r)}_2 | 0 < r \leq l \} \cup \{ \varepsilon^{(r)} | s_{1,2} < r \leq s_{1,2} + k \} \cup \{ f^{(r)} | s_{2,1} < r \leq s_{2,1} + k \}.
\]

To prove the lemma, it suffices to show that \( M \) is linearly independent in \( \text{gr} Y^{l}_\sigma \). For this, we proceed by induction on \( s_{2,1} + s_{1,2} \).

To establish the base case \( s_{2,1} + s_{1,2} = 0 \), i.e., \( \sigma = 0 \), \( Y_\sigma = Y \) and \( Y^{l}_\sigma = Y^{l} \), let \( t^{(r)}_{i,j} \) denote \( \text{gr}_r (\text{ev}^l_\sigma (t^{(r)}_{i,j})) \). Fix a total order on \( \{ t^{(r)}_{i,j} | 1 \leq i, j \leq 2, \ 0 < r \leq l \} \), and let \( M' \) be the resulting set of ordered supermonomials. Exploiting the explicit formula (3-4), Gow [2007, proof of Theorem 1] shows that \( M' \) is linearly independent. By (2-6)–(2-9), any element of \( M \) is a linear combination of elements of \( M' \) of the same degree and vice versa. So we deduce that \( M \) is linearly independent too.

For the induction step, suppose that \( s_{2,1} + s_{1,2} > 0 \). Then we either have \( s_{2,1} > 0 \) or \( s_{1,2} > 0 \). We just explain the argument for the latter case; the proof in the former case is entirely similar replacing \( \Delta_+ \) with \( \Delta_- \). Recall that \( \sigma_+ \) denotes the shift matrix obtained from \( \sigma \) by subtracting 1 from \( s_{1,2} \). So \( U^{l}_\sigma = U^{l-1}_{\sigma_+} \otimes U (\mathfrak{gl}_1) \). By its definition, we have that \( \text{ev}^l_\sigma = (\text{ev}^{l-1}_{\sigma_+} \otimes \text{id}) \circ \Delta_+ \); hence, \( Y^{l}_\sigma \subseteq Y^{l-1}_{\sigma_+} \otimes U (\mathfrak{gl}_1) \). Let
Theorem 3.5. The notation is potentially confusing here, so we have decorated elements of \( \text{gr} \ Y_{\sigma+}^{l-1} \) with a dot. It remains to observe from the induction hypothesis applied to \( \text{gr} \ Y_{\sigma+}^{l-1} \) that ordered supermonomials in

\[ d_1^{(r)} = d_1^{(r)} \otimes 1, \quad d_2^{(r)} = d_2^{(r)} \otimes 1 + (-1)^{|2|} \tilde{d}_2^{(r-1)} \otimes x, \]

\[ \tilde{f}^{(r)} = \tilde{f}^{(r)} \otimes 1, \quad \tilde{e}^{(r)} = \tilde{e}^{(r)} \otimes 1 + (-1)^{|2|} \tilde{e}^{(r-1)} \otimes x. \]

The notation is potentially confusing here, so we have decorated elements of \( \text{gr} \ Y_{\sigma+}^{l-1} \subseteq \text{gr} \ U_{\sigma+}^{l-1} \) with a dot. It remains to observe from the induction hypothesis applied to \( \text{gr} \ Y_{\sigma+}^{l-1} \) that ordered supermonomials in

\[ \{ \tilde{d}_1^{(r)} \otimes 1 \mid 0 < r \leq k \} \cup \{ \tilde{d}_2^{(r-1)} \otimes x \mid 0 < r \leq l \} \]

\[ \cup \{ \tilde{e}^{(r-1)} \otimes x \mid s_{1,2} < r \leq s_{1,2} + k \} \cup \{ \tilde{f}^{(r)} \otimes 1 \mid 0 < r < s_{1,2} + k \} \]

are linearly independent. \( \square \)

**Theorem 3.5.** The kernel of \( \text{ev}_\sigma^j : Y_\sigma \rightarrow Y_\sigma^j \) is equal to the two-sided ideal \( I_\sigma^j \) generated by the elements \( \{ d_1^{(r)} \mid r > k \} \). Hence, \( \text{ev}_\sigma^j \) induces an algebra isomorphism between \( Y_\sigma/I_\sigma^j \) and \( Y_\sigma^j \).

**Proof.** By Lemma 3.1, \( \text{ev}_\sigma^j \) induces a surjection \( Y_\sigma/I_\sigma^j \rightarrow Y_\sigma^j \). It maps the spanning set from Lemma 3.3 onto the linearly independent set from Lemma 3.4. Hence, it is an isomorphism and both sets are actually bases. \( \square \)

Henceforth, we will identify \( Y_\sigma^j \) with the quotient \( Y_\sigma/I_\sigma^j \), and we will abuse notation by denoting the canonical images in \( Y_\sigma^j \) of the elements \( d_i^{(r)}, e^{(r)}, \ldots \) of \( Y_\sigma \) by the same symbols \( d_i^{(r)}, e^{(r)}, \ldots \). This will not cause any confusion as we will not work with \( Y_\sigma \) again.

Here is the PBW theorem for \( Y_\sigma^j \), which was noted already in the proof of Theorem 3.5.

**Corollary 3.6.** Order the set

\[ \{ d_1^{(r)} \mid 0 < r \leq k \} \cup \{ d_2^{(r)} \mid 0 < r \leq l \} \]

\[ \cup \{ e^{(r)} \mid s_{1,2} < r \leq s_{1,2} + k \} \cup \{ f^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k \} \]

in some way. The ordered supermonomials in these elements give a basis for \( Y_\sigma^j \).

**Remark 3.7.** In the arguments in this section, we have defined two filtrations on \( Y_\sigma^j \): one in the proof of Lemma 3.3 induced by the Kazhdan filtration on \( Y_\sigma \) and the other in the proof of Lemma 3.4 induced by the standard filtration on \( U_\sigma^j \). Using Corollary 3.6, one can check that these two filtrations coincide.

**Remark 3.8.** Theorem 3.5 shows that \( Y_\sigma^j \) has generators

\[ \{ d_i^{(r)} \mid i = 1, 2, \ r > 0 \} \cup \{ e^{(r)} \mid r > s_{1,2} \} \cup \{ f^{(r)} \mid r > s_{2,1} \} \]

subject only to the relations from Theorem 2.2 and the additional truncation relations \( d_1^{(r)} = 0 \) for \( r > k \). Corollary 3.6 shows that all but finitely many of the generators
are redundant. In special cases, it is possible to optimize the relations too. For example, if \( l = s_{2,1} + s_{1,2} + 1 \) and we set \( d := d_1^{(1)} \), \( e := e^{(s_{1,2}+1)} \) and \( f := f^{(s_{2,1}+1)} \), then \( Y'_\sigma \) is generated by its even central elements \( c^{(1)}, \ldots, c^{(l)} \) from (2-10), the even element \( d \) and the odd elements \( e \) and \( f \) subject only to the relations

\[
[d, e] = (-1)^{|l|} e, \quad [d, f] = -(-1)^{|l|} f, \quad [e, f] = (-1)^{|l|} c^{(l)}, \quad [c^{(r)}, c^{(s)}] = [c^{(r)}, d] = [c^{(r)}, e] = [c^{(r)}, f] = [e, e] = [f, f] = 0,
\]

for \( r, s = 1, \ldots, l \). To see this, observe that these elements generate \( Y'_\sigma \) and they satisfy the given relations; then apply Corollary 3.6.

### 4. Principal \( W \)-algebras

We turn to the \( W \)-algebra side of the story. Let \( \pi \) be a (two-rowed) pyramid, that is, a collection of boxes in the plane arranged in two connected rows such that each box in the first (top) row lies directly above a box in the second (bottom) row. For example, here are all the pyramids with two boxes in the first row and five in the second:

\[
\begin{array}{cccc}
\Box & \Box & \Box & \Box \\
\Box & \Box & \Box & \Box & \Box
\end{array}
\]

\[
\begin{array}{cccc}
\Box & \Box & \Box & \Box \\
\Box & \Box & \Box & \Box & \Box
\end{array}
\]

\[
\begin{array}{cccc}
\Box & \Box & \Box & \Box \\
\Box & \Box & \Box & \Box & \Box
\end{array}
\]

\[
\begin{array}{cccc}
\Box & \Box & \Box & \Box \\
\Box & \Box & \Box & \Box & \Box
\end{array}
\]

Let \( k \) and \( l \) denote the number of boxes in the first and second rows of \( \pi \), respectively, so that \( k \leq l \). The parity sequence fixed in (2-1) allows us to talk about the parities of the rows of \( \pi \): the \( i \)-th row is of parity \( |i| \). Let \( m \) be the number of boxes in the even row, i.e., the row with parity \( \tilde{0} \), and \( n \) be the number of boxes in the odd row, i.e., the row with parity \( \tilde{1} \). Then label the boxes in the even and odd rows from left to right by the numbers \( 1, \ldots, m \) and \( m + 1, \ldots, m + n \), respectively. For example, here is one of the above pyramids with boxes labeled in this way assuming that \( (|1|, |2|) = (\tilde{1}, \tilde{0}) \), i.e., the bottom row is even and the top row is odd:

\[
\begin{array}{cccc}
\Box & \Box & \Box & \Box \\
\Box & \Box & \Box & \Box & \Box
\end{array}
\]

Numbering the columns of \( \pi \) \( 1, \ldots, l \) in order from left to right, we write \( \text{row}(i) \) and \( \text{col}(i) \) for the row and column numbers of the \( i \)-th box in this labeling.

Now let \( \mathfrak{g} := \mathfrak{gl}_{m|n}(\mathbb{C}) \) for \( m \) and \( n \) coming from the pyramid \( \pi \) and the fixed parity sequence as in the previous paragraph. Let \( \mathfrak{t} \) be the Cartan subalgebra consisting of all diagonal matrices and \( \varepsilon_1, \ldots, \varepsilon_{m+n} \in \mathfrak{t}^* \) the basis such that \( \varepsilon_i(e_{j,j}) = \delta_{i,j} \) for each \( j = 1, \ldots, m + n \). The supertrace form \( (\cdot | \cdot) \) on \( \mathfrak{g} \) is the nondegenerate invariant supersymmetric bilinear form defined by \( (x | y) = \text{str}(xy) \), where the supertrace \( \text{str} A \) of matrix \( A = (a_{i,j})_{1 \leq i, j \leq m+n} \) means \( a_{1,1} + \cdots + a_{m,m} - a_{m+1,m+1} - \cdots - a_{m+n,m+n} \). It induces a bilinear form \( (\cdot | \cdot) \) on \( \mathfrak{t}^* \) such that \( (\varepsilon_i | \varepsilon_j) = (-1)^{|\text{row}(i)|} \delta_{i,j} \).
We have the explicit principal nilpotent element
\[ e := \sum_{i, j} e_{i, j} \in g_0 \]  (4-2)
summing over all adjacent pairs \([i/j]\) of boxes in the pyramid \(\pi\). In the example above, we have that \(e = e_{1,2} + e_{2,3} + e_{3,4} + e_{4,5} + e_{6,7}\). Let \(\chi \in g^*\) be defined by \(\chi(x) := (x|e)\). If we set
\[ \bar{e}_{i, j} := (-1)^{|\text{row}(i)|} e_{i, j}, \]  (4-3)
then we have that
\[ \chi(\bar{e}_{i, j}) = \begin{cases} 1 & \text{if } [j/i] \text{ is an adjacent pair of boxes in } \pi, \\ 0 & \text{otherwise}. \end{cases} \]  (4-4)
Introduce a \(\mathbb{Z}\)-grading \(g = \bigoplus_{r \in \mathbb{Z}} g(r)\) by declaring that \(e_{i, j}\) is of degree
\[ \deg(e_{i, j}) := \text{col}(j) - \text{col}(i). \]  (4-5)
This is a good grading for \(e\), which means that \(e \in g(1)\) and the centralizer \(g^e\) of \(e\) in \(g\) is contained in \(\bigoplus_{r \geq 0} g(r)\); see [Hoyt 2012] for more about good gradings on Lie superalgebras (one should double the degrees of our grading to agree with the terminology there). Set
\[ p := \bigoplus_{r \geq 0} g(r), \quad h := g(0), \quad m := \bigoplus_{r < 0} g(r). \]
Note that \(\chi\) restricts to a character of \(m\). Let \(m_{\chi} := \{x - \chi(x) | x \in m\}\), which is a shifted copy of \(m\) inside \(U(m)\). Then the principal \(W\)-algebra associated to the pyramid \(\pi\) is
\[ W_{\pi} := \{u \in U(p) | um_{\chi} \subseteq m_{\chi}U(g)\}. \]  (4-6)
It is straightforward to check that \(W_{\pi}\) is a subalgebra of \(U(p)\).

The first important result about \(W_{\pi}\) is its PBW theorem. This is noted already in [Zhao 2012, Remark 3.10], where it is described for arbitrary basic classical Lie superalgebras modulo a mild assumption on \(e\) (which is trivially satisfied here). To formulate the result precisely, embed \(e\) into an \(\mathfrak{sl}_2\)-triple \((e, h, f)\) in \(g_0\) such that \(h \in g(0)\) and \(f \in g(-1)\). It follows from \(\mathfrak{sl}_2\) representation theory that
\[ p = g^e \oplus [p^\perp, f], \]  (4-7)
where \(p^\perp = \bigoplus_{r > 0} g(r)\) denotes the nilradical of \(p\). Also introduce the Kazhdan filtration on \(U(p)\), which is generated by declaring for each \(r \geq 0\) that \(x \in g(r)\) is of Kazhdan degree \(r + 1\). The associated graded superalgebra \(\text{gr} U(p)\) is supercommutative and is naturally identified with the symmetric superalgebra \(S(p)\) viewed as a positively graded algebra via the analogously defined Kazhdan grading. The
Kazhdan filtration on \(U(p)\) induces a Kazhdan filtration on \(W_\pi \subseteq U(p)\) so that \(\text{gr } W_\pi \subseteq \text{gr } U(p) = S(p)\).

**Theorem 4.1.** Let \(p : S(p) \to S(g^e)\) be the homomorphism induced by the projection of \(p\) onto \(g^e\) along (4-7). The restriction of \(p\) defines an isomorphism of Kazhdan-graded superalgebras \(\text{gr } W_\pi \cong S(g^e)\).

**Proof.** Superize the arguments in [Gan and Ginzburg 2002] as suggested in [Zhao 2012, Remark 3.10]. □

In order to apply Theorem 4.1, it is helpful to have available an explicit basis for the centralizer \(g^e\). We say that a shift matrix \(\sigma = (s_{i,j})_{1 \leq i, j \leq 2}\) is compatible with \(\pi\) if either \(k > 0\) and \(\pi\) has \(s_{2,1}\) columns of height 1 on its left side and \(s_{1,2}\) columns of height 1 on its right side or if \(k = 0\) and \(l = s_{2,1} + s_{1,2}\). These conditions determine a unique shift matrix \(\sigma\) when \(k > 0\), but there is some minor ambiguity if \(k = 0\) (which should never cause any concern). For example, if \(\pi\) is as in (4-1), then

\[
\sigma = \begin{pmatrix}
0 & 2 \\
1 & 0
\end{pmatrix}
\]

is the only compatible shift matrix.

**Lemma 4.2.** Let \(\sigma = (s_{i,j})_{1 \leq i, j \leq 2}\) be a shift matrix compatible with \(\pi\). For \(r \geq 0\), let

\[
x_{i,j}^{(r)} := \sum_{\substack{1 \leq p, q \leq m+n \\
\text{row}(p) = i, \text{row}(q) = j \\
\text{deg}(e_{p,q}) = r-1}} \tilde{e}_{p,q} \in g(r-1).
\]

Then the elements

\[
\{x_{1,1}^{(r)} \mid 0 < r \leq k\} \cup \{x_{2,2}^{(r)} \mid 0 < r \leq l\} \\
\cup \{x_{1,2}^{(r)} \mid s_{1,2} < r \leq s_{1,2} + k\} \cup \{x_{2,1}^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k\}
\]

give a homogeneous basis for \(g^e\).

**Proof.** As \(e\) is even, the centralizer of \(e\) in \(g\) is just the same as a vector space as the centralizer of \(e\) viewed as an element of \(gl_{m+n}(\mathbb{C})\), so this follows as a special case of [Brundan and Kleshchev 2006, Lemma 7.3] (which is [Springer and Steinberg 1970, IV.1.6]). □

We come to the key ingredient in our approach: the explicit definition of special elements of \(U(p)\), some of which turn out to generate \(W_\pi\). Define another ordering \(\prec\) on the set \(\{1, \ldots, m+n\}\) by declaring that \(i \prec j\) if \(\text{col}(i) < \text{col}(j)\) or if \(\text{col}(i) = \text{col}(j)\) and \(\text{row}(i) < \text{row}(j)\). Let \(\tilde{\rho} \in \mathfrak{t}^*\) be the weight with

\[
(\tilde{\rho}|e_j) = \#\{i \mid i \leq j \text{ and } |\text{row}(i)| = 1\} - \#\{i \mid i < j \text{ and } |\text{row}(i)| = 0\}.
\]

(4-8)
For example, if $\pi$ is as in (4-1), then $\tilde{\rho} = -\varepsilon_4 - 2\varepsilon_5$. The weight $\tilde{\rho}$ extends to a character of $\mathfrak{p}$, so there are automorphisms
\[
S_{\pm \tilde{\rho}} : U(\mathfrak{p}) \to U(\mathfrak{p}), \quad e_{i,j} \mapsto e_{i,j} \pm \delta_{i,j} \tilde{\rho}(e_{i,i}). \tag{4-9}
\]

Finally, given $1 \leq i, j \leq 2$, $0 \leq \varsigma \leq 2$ and $r \geq 1$, we define
\[
t_{i,j;\varsigma}^{(r)} := S_{\tilde{\rho}} \left( \sum_{s=1}^{r} (-1)^{r-s} \sum_{i_1, \ldots, i_s, j_1, \ldots, j_s \leq m+n \text{ such that}} (-1)^{# \{a=1, \ldots, s-1 \mid \text{row}(j_a) \leq \varsigma \}} \varepsilon_{i_1,j_1} \cdots \varepsilon_{i_s,j_s} \right), \tag{4-10}
\]
where the sum is over all $1 \leq i_1, \ldots, i_s, j_1, \ldots, j_s \leq m+n$ such that

- row$(i_1) = i$ and row$(j_s) = j$,
- col$(i_a) \leq \text{col}(j_a)$ ($a = 1, \ldots, s$),
- row$(i_{a+1}) = \text{row}(j_a)$ ($a = 1, \ldots, s-1$),
- if row$(j_a) > \varsigma$, then col$(i_{a+1}) > \text{col}(j_a)$ ($a = 1, \ldots, s-1$),
- if row$(j_a) \leq \varsigma$, then col$(i_{a+1}) \leq \text{col}(j_a)$ ($a = 1, \ldots, s-1$) and
- deg$(e_{i_1,j_1}) + \cdots + \text{deg}(e_{i_s,j_s}) = r-s$.

It is convenient to collect these elements together into the generating function
\[
t_{i,j;\varsigma}(u) := \sum_{r \geq 0} t_{i,j;\varsigma}^{(r)} u^{-r} \in U(\mathfrak{p})[[u^{-1}]] \tag{4-11}
\]
setting $t_{i,j;\varsigma}^{(0)} := \delta_{i,j}$. The following two propositions should already convince the reader of the remarkable nature of these elements:

\textbf{Proposition 4.3.} The following identities hold in $U(\mathfrak{p})[[u^{-1}]]$:

\begin{align*}
t_{1,1;1}(u) &= t_{1,1;0}(u)^{-1}, \tag{4-12} \\
t_{2,2;2}(u) &= t_{2,2;1}(u)^{-1}, \tag{4-13} \\
t_{1,2;0}(u) &= t_{1,1;0}(u)t_{1,2;1}(u), \tag{4-14} \\
t_{2,1;0}(u) &= t_{2,1;1}(u)t_{1,1;0}(u), \tag{4-15} \\
t_{2,2;0}(u) &= t_{2,2;1}(u) + t_{2,1;1}(u)t_{1,1;0}(u)t_{1,2;1}(u). \tag{4-16}
\end{align*}

\textbf{Proof.} This is proved in [Brundan and Kleshchev 2006, Lemma 9.2]; the argument there is entirely formal and does not depend on the underlying associative algebra in which the calculations are performed. \hfill \Box

\textbf{Proposition 4.4.} Let $\sigma$ be a shift matrix compatible with $\pi$. The following elements of $U(\mathfrak{p})$ belong to $W_\pi$: all $t_{1,1;0}^{(r)}$, $t_{1,1;1}^{(r)}$, $t_{2,2;1}^{(r)}$ and $t_{2,2;2}^{(r)}$ for $r > 0$, all $t_{1,2;1}^{(r)}$ for $r > s_{1,2}$ and all $t_{2,1;1}^{(r)}$ for $r > s_{2,1}$.

\textbf{Proof.} This is postponed to Section 5. \hfill \Box
Now we can deduce our main result. For any shift matrix $\sigma$ compatible with $\pi$, we identify $U(h)$ with the algebra $U_{\sigma}^l$ from (3-1) so that

$$e_{i,j} \equiv \begin{cases} 1^{\otimes (c-1)} \otimes e_{\text{row}(i),\text{row}(j)} \otimes 1^{\otimes (l-c)} & \text{if } q_c = 2, \\ 1^{\otimes (c-1)} \otimes e_{1,1} \otimes 1^{\otimes (l-c)} & \text{if } q_c = 1 \end{cases}$$

for any $1 \leq i, j \leq m + n$ with $c := \text{col}(i) = \text{col}(j)$, where $q_c$ denotes the number of boxes in this column of $\pi$. Define the Miura transform

$$\mu : W_{\pi} \rightarrow U(h) = U_{\sigma}^l$$

(4-17)

to be the restriction to $W_{\pi}$ of the shift automorphism $S_{-\hat{h}}$ composed with the natural homomorphism $\text{pr} : U(p) \rightarrow U(h)$ induced by the projection $p \rightarrow h$.

**Theorem 4.5.** Let $\sigma$ be a shift matrix compatible with $\pi$. The Miura transform is injective, and its image is the algebra $Y_{\sigma}^l \subseteq U_{\sigma}^l$ from (3-3). Hence, it defines a superalgebra isomorphism

$$\mu : W_{\pi} \rightarrow Y_{\sigma}^l$$

(4-18)

between $W_{\pi}$ and the shifted Yangian of level $l$. Moreover, $\mu$ maps the invariants from Proposition 4.4 to the Drinfeld generators of $Y_{\sigma}^l$ as follows:

$$\mu(t_{1,1;0}^{(r)}) = d_{1}^{(r)} \quad (r > 0), \quad \mu(t_{1,1;1}^{(r)}) = \tilde{d}_{1}^{(r)} \quad (r > 0), \quad (4-19)$$

$$\mu(t_{2,2;1}^{(r)}) = d_{2}^{(r)} \quad (r > 0), \quad \mu(t_{2,2;2}^{(r)}) = \tilde{d}_{2}^{(r)} \quad (r > 0), \quad (4-20)$$

$$\mu(t_{1,2;1}^{(r)}) = e^{(r)} \quad (r > s_{1,2}), \quad \mu(t_{2,1;1}^{(r)}) = f^{(r)} \quad (r > s_{2,1}). \quad (4-21)$$

**Proof.** We first establish the identities (4-19)–(4-21). Note that the identities involving $d_{i}^{(r)}$ are consequences of the ones involving $d_{i}^{(r)}$ thanks to (4-12) and (4-13) recalling also that $\tilde{d}_{i}(u) = d_{i}(u)^{-1}$. To prove all the other identities, we proceed by induction on $s_{2,1} + s_{1,2} = l - k$.

First consider the base case $l = k$. For $1 \leq i, j \leq 2$ and $r > 0$, we know in this situation that $t_{i,j;0}^{(r)} \in W_{\pi}$ since, using (4-14)–(4-16), it can be expanded in terms of elements all of which are known to lie in $W_{\pi}$ by Proposition 4.4; see also Lemma 5.1. Moreover, we have directly from (4-10) and (3-4) that $\mu(t_{i,j;0}^{(r)}) = t_{i,j}^{(r)} \in Y_{\pi}^l$. Hence, $\mu(t_{i,j;0}(u)) = t_{i,j}(u)$. The result follows from this, (2-6), (2-7) and the analogous expressions for $t_{1,1;0}(u), t_{2,2;1}(u), t_{1,2;1}(u)$ and $t_{2,1;1}(u)$ derived from (4-14)–(4-16).

Now consider the induction step, so $s_{2,1} + s_{1,2} > 0$. There are two cases according to whether $s_{2,1} > 0$ or $s_{1,2} > 0$. We just explain the argument for the latter situation since the former is entirely similar. Let $\hat{\pi}$ be the pyramid obtained from $\pi$ by removing the rightmost column, and let $W_{\hat{\pi}}$ be the corresponding finite $W$-algebra. We denote its Miura transform by $\hat{\mu} : W_{\hat{\pi}} \rightarrow U_{\sigma_+}^{l-1}$ and similarly decorate all other notation related to $\hat{\pi}$ with a dot to avoid confusion. Now we proceed to show that $\mu(t_{1,2;1}^{(r)}) = e^{(r)}$ for each $r > s_{1,2}$. By induction, we know that $\hat{\mu}(i_{1,2;1}^{(r)}) = \hat{e}^{(r)}$ for
each $r \geq s_{1,2}$. But then it follows from the explicit form of (4-10), together with (2-15) and the definition of the evaluation homomorphism (3-2), that
\[
\mu(t_{1,2;1}^{(r)}) = \mu(t_{1,2;1}^{(r)}) \otimes 1 + (-1)^{|t_{1,2;1}^{(r-1)}}| \otimes e_{1,1} \\
= e^{(r)} \otimes 1 + (-1)^{|e^{(r-1)}|} \otimes e_{1,1} = e^{(r)}
\]
providing $r > s_{1,2}$. The other cases are similar.

Now we deduce the rest of the theorem from (4-19)–(4-21). Order the elements of
\[
\Omega := \{t_{1,1;1}^{(r)} \mid 0 < r \leq k\} \cup \{t_{2,2;1}^{(r)} \mid 0 < r \leq l\} \\
\cup \{t_{1,2;1}^{(r)} \mid s_{1,2} < r \leq s_{1,2} + k\} \cup \{t_{2,1;1}^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k\}
\]
in some way. By Proposition 4.4, each $t_{i,j;\xi}^{(r)} \in \Omega$ belongs to $W_\pi$. Moreover, from the definition (4-10), it is in filtered degree $r$ and $\text{gr}_r t_{i,j;\xi}^{(r)}$ is equal up to a sign to the element $x_{i,j}^{(r)}$ from Lemma 4.2 plus a linear combination of monomials in elements of strictly smaller Kazhdan degree. Using Theorem 4.1, we deduce that the set of all ordered supermonomials in the set $\Omega$ gives a linear basis for $W_\pi$. By (4-19)–(4-21) and Corollary 3.6, $\mu$ maps this basis onto a basis for $Y_\sigma^l \subseteq U_\sigma^l$. Hence, $\mu$ is an isomorphism.

Remark 4.6. The grading $p = \bigoplus_{r \geq 0} g(r)$ induces a grading on the superalgebra $U(p)$. However, $W_\pi$ is not a graded subalgebra. Instead, we get induced another filtration on $W_\pi$, with respect to which the associated graded superalgebra $\text{gr}' W_\pi$ is identified with a graded subalgebra of $U(p)$. From Proposition 4.4, each of the invariants $t_{i,j;\xi}^{(r)}$ belongs to filtered degree $r - 1$ and has image $(-1)^{r-1}x_{i,j}^{(r)}$ in the associated graded algebra. Combined with Lemma 4.2 and the usual PBW theorem for $g^e$, it follows that $\text{gr}' W_\pi = U(g^e)$. Moreover, this filtration on $W_\pi$ corresponds under the isomorphism $\mu$ to the filtration on $Y_\sigma^l$ induced by the Lie filtration on $Y_\sigma$.

Remark 4.7. In this section, we have worked with the “right-handed” definition (4-6) of the finite $W$-algebra. One can also consider the “left-handed” version
\[
W_\pi^\dag := \{u \in U(p) \mid m_\chi u \subseteq U(g)m_\chi\}.
\]
There is an analogue of Theorem 4.5 for $W_\pi^\dag$, via which one sees that $W_\pi \cong W_\pi^\dag$. More precisely, we define the “left-handed” Miura transform $\mu^\dag : W_\pi^\dag \to U(h)$ as above but twisting with the shift automorphism $S_{-\tilde{\rho}^\dag}$ rather than $S_{-\tilde{\rho}}$, where
\[
(\tilde{\rho}^\dag | e_j) = \#\{i \mid i \preceq j \text{ and } |\text{row}(i)| = \bar{1}\} - \#\{i \mid i \prec j \text{ and } |\text{row}(i)| = \bar{0}\} \tag{4-22}
\]
and $i \prec j$ means either $\text{col}(i) > \text{col}(j)$, or $\text{col}(i) = \text{col}(j)$ and $\text{row}(i) < \text{row}(j)$. The analogue of Theorem 4.5 asserts that $\mu^\dag$ is injective with the same image as $\mu$. Hence, $\mu^{-1} \circ \mu^\dag$, i.e., the restriction of the shift $S_{-\tilde{\rho}^\dag} : U(p) \to U(p)$, gives an isomorphism between $W_\pi^\dag$ and $W_\pi$. Noting that
\[
\tilde{\rho} - \tilde{\rho}^\dag = \sum_{1 \leq i,j \leq m+n \atop \text{col}(i) < \text{col}(j)} (-1)^{|\text{row}(i)|+|\text{row}(j)|} (\varepsilon_i - \varepsilon_j), \tag{4-23}
\]
there is a more conceptual explanation for this isomorphism along the lines of the proof given in the nonsuper case in [Brundan et al. 2008, Corollary 2.9].

**Remark 4.8.** Another consequence of Theorem 4.5 together with Remarks 2.9 and 2.1 is that up to isomorphism the algebra $W_\pi$ depends only on the set $\{m, n\}$, i.e., on the isomorphism type of $\mathfrak{g}$ and not on the particular choice of the pyramid $\pi$ or the parity sequence. As observed in [Zhao 2012, Remark 3.10], this can also be proved by mimicking [Brundan and Goodwin 2007, Theorem 2].

5. Proof of invariance

In this section, we prove Proposition 4.4. We keep all notation as in the statement of the proposition. Showing that $u \in U(\mathfrak{p})$ lies in the algebra $W_\pi$ is equivalent to showing that $[x, u] \in m_\chi U(\mathfrak{g})$ for all $x \in m$ or even just for all $x$ in a set of generators for $m$. Let

$$\Omega := \{t_{1,1;0}^{(r)} | r > 0\} \cup \{t_{1,2;1}^{(r)} | r > s_{1,2}\} \cup \{t_{2,1;1}^{(r)} | r > s_{2,1}\} \cup \{t_{2,2;1}^{(r)} | r > 0\}. \quad (5-1)$$

Our goal is to show that $[x, u] \in m_\chi U(\mathfrak{g})$ for $x$ running over a set of generators of $m$ and $u \in \Omega$. Proposition 4.4 follows from this since all the other elements listed in the statement of the proposition can be expressed in terms of elements of $\Omega$ thanks to Proposition 4.3. Also observe for the present purposes that there is some freedom in the choice of the weight $\tilde{\rho}$: it can be adjusted by adding on any multiple of “supertrace” $\epsilon_1 + \cdots + \epsilon_m - \epsilon_{m+1} - \cdots - \epsilon_{m+n}$. This just twists the elements $t_{i,j;\tilde{\rho}}^{(r)}$ by an automorphism of $U(\mathfrak{g})$ so does not have any effect on whether they belong to $W_\pi$. So sometimes in this section we will allow ourselves to change the choice of $\tilde{\rho}$.

**Lemma 5.1.** Assuming $k = l$, we have that $[x, t_{i,j;0}^{(r)}] \in m_\chi U(\mathfrak{g})$ for all $x \in m$ and $r > 0$.

**Proof.** Note when $k = l$ that $\tilde{\rho} = \epsilon_1 + \cdots + \epsilon_m - \epsilon_{m+1} - \cdots - \epsilon_{m+n}$ if $(|1|, |2|) = (\bar{1}, \bar{0})$ and $\tilde{\rho} = 0$ if $(|1|, |2|) = (\bar{0}, \bar{1})$. As noted above, it does no harm to change the choice of $\tilde{\rho}$ to assume in fact that $\tilde{\rho} = 0$ in both cases. Now we proceed to mimic the argument in [Brundan and Kleshchev 2006, §12].

Consider the tensor algebra $T(M_l)$ in the (purely even) vector space $M_l$ of $l \times l$ matrices over $\mathbb{C}$. For $1 \leq i, j \leq 2$, define a linear map $t_{i,j} : T(M_l) \to U(\mathfrak{g})$ by setting

$$t_{i,j}(1) := \delta_{i,j}, \quad t_{i,j}(e_{a,b}) := (-1)^{|i|} e_{i*a,j*b},$$

$$t_{i,j}(x_1 \otimes \cdots \otimes x_r) := \sum_{1 \leq h_1, \ldots, h_{r-1} \leq 2} t_{i,h_1}(x_1) t_{h_1,h_2}(x_2) \cdots t_{h_{r-1},j}(x_r)$$
for \( 1 \leq a, b \leq l, r \geq 1 \) and \( x_1, \ldots, x_r \in M_l \), where \( i \ast a \) denotes \( a \) if \( |i| = 0 \) and \( l + a \) if \( |i| = 1 \). It is straightforward to check for \( x, y_1, \ldots, y_r \in M_l \) that

\[
[t_{i, j}(x), t_{p, q}(y_1 \otimes \cdots \otimes y_r)]
\]

\[
= (-1)^{|i||j|+|p||j|+|p|} \sum_{s=1}^{r} (t_{p, j}(y_1 \otimes \cdots \otimes y_{s-1}) t_{i, q}(xy_s \otimes \cdots \otimes y_r)
\]

\[
- t_{p, j}(y_1 \otimes \cdots \otimes y_s x) t_{i, q}(y_{s+1} \otimes \cdots \otimes y_r),
\]

(5-2)

where the products \( xy_s \) and \( y_s x \) on the right are ordinary matrix products in \( M_l \). We extend \( t_{i, j} \) to a \( \mathbb{C}[u] \)-module homomorphism \( T(M_l)[u] \rightarrow U(\mathfrak{g})[u] \) in the obvious way. Introduce the following matrix with entries in the algebra \( T(M_l)[u] \):

\[
A(u) :=
\begin{pmatrix}
  u + e_{1,1} & e_{1,2} & e_{1,3} & \cdots & e_{1,l} \\
  1 & u + e_{2,2} & \vdots & & \vdots \\
  0 & \ddots & e_{l-2,l} & & \\
  \vdots & & \ddots & 1 & u + e_{l-1,l} \\
  0 & \cdots & 0 & 1 & u + e_{l,l}
\end{pmatrix}
\]

The point is that \( t_{i, j; 0}(u) = u^{-1}t_{i, j}(\text{cdet } A(u)) \), where the column determinant of an \( l \times l \) matrix \( A = (a_{i, j}) \) with entries in a noncommutative ring means the Laplace expansion keeping all the monomials in column order, i.e.,

\[
\text{cdet } A := \sum_{w \in S_l} \text{sgn}(w)a_{w(1), 1} \cdots a_{w(l), l}.
\]

We also write \( A_{c, d}(u) \) for the submatrix of \( A(u) \) consisting only of rows and columns numbered \( c, \ldots, d \).

Since \( \mathfrak{m} \) is generated by elements of the form \( t_{i, j}(e_{c+1, c}) \), it suffices now to show that \( [t_{i, j}(e_{c+1, c}), t_{p, q}(\text{cdet } A(u))] \in \mathfrak{m}_x U(\mathfrak{g}) \) for every \( 1 \leq i, j, p, q \leq 2 \) and \( c = 1, \ldots, l - 1 \). To do this, we compute using the identity (5-2):

\[
[t_{i, j}(e_{c+1, c}), t_{p, q}(\text{cdet } A(u))]
\]

\[
= t_{p, j}(\text{cdet } A_{1, c-1}(u)) t_{i, q} \begin{pmatrix}
 e_{c+1, c} & e_{c+1, c+1} & \cdots & e_{c+1, l} \\
 1 & u + e_{c+1, c+1} & \cdots & e_{c+1, l} \\
 \vdots & \ddots & \ddots & \vdots \\
 0 & \cdots & 1 & u + e_{l,l}
\end{pmatrix}
\]

\[
- t_{p, j} \begin{pmatrix}
 u + e_{1,1} & \cdots & e_{1,c} & e_{1,c} \\
 1 & \ddots & \vdots & \vdots \\
 \vdots & u + e_{c,c} & e_{c,c} & \\
 0 & \cdots & 1 & e_{c+1,c}
\end{pmatrix}
\]

\[
\text{cdet } \begin{pmatrix}
 u + e_{1,1} & \cdots & e_{1,c} & e_{1,c} \\
 1 & \ddots & \vdots & \vdots \\
 \vdots & u + e_{c,c} & e_{c,c} & \\
 0 & \cdots & 1 & e_{c+1,c}
\end{pmatrix}
\]

\[
t_{i, q}(\text{cdet } A_{c+2, l}(u)).
\]
In order to simplify the second term on the right-hand side, we observe crucially for \( h = 1, 2 \) that \( t_{h,j}((u + e_{c,c})e_{c+1,c}) \equiv t_{h,j}(u + e_{c,c}) \pmod{m_\chi U(g)} \). Hence, we get that

\[
[t_{i,j}(e_{c+1,c}), t_{p,q}(\text{cdet } A(u))] \equiv t_{p,j}(\text{cdet } A_{1,c-1}(u))t_{i,q} \begin{pmatrix}
1 & e_{c+1,c+1} & \cdots & e_{c+1,l} \\
1 & u + e_{c+1,c+1} & \cdots & e_{c+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & u + e_{l,l}
\end{pmatrix}
\]

modulo \( m_\chi U(g) \). Making the obvious row and column operations gives that

\[
\begin{pmatrix}
1 & e_{c+1,c+1} & \cdots & e_{c+1,l} \\
1 & u + e_{c+1,c+1} & \cdots & e_{c+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & u + e_{l,l}
\end{pmatrix} = u \begin{pmatrix}
1 & e_{c+1,c+1} & \cdots & e_{c+1,l} \\
1 & u + e_{c+1,c+1} & \cdots & e_{c+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & u + e_{l,l}
\end{pmatrix}
\]

It remains to substitute these into the preceding formula. \( \square \)

**Proof of Proposition 4.4.** Our argument goes by induction on \( s_{2,1} + s_{1,2} = l - k \). For the base case \( k = l \), we use Proposition 4.3 to rewrite the elements of \( \Omega \) in terms of the elements \( t_{i,j;0}^{(r)} \). The latter lie in \( W_\pi \) by Lemma 5.1. Hence, so do the former.

Now assume that \( s_{2,1} + s_{1,2} > 0 \). There are two cases according to whether \( s_{1,2} \geq s_{2,1} \) or \( s_{2,1} > s_{1,2} \). Suppose first that \( s_{1,2} \geq s_{2,1} \) and hence that \( s_{1,2} > 0 \). We may as well assume in addition that \( l \geq 2 \): the result is trivial for \( l \leq 1 \) as \( m = \{0\} \).

Let \( \hat{\pi} \) be the pyramid obtained from \( \pi \) by removing the rightmost column. We will decorate all notation related to \( \hat{\pi} \) with a dot to avoid any confusion. In particular, \( W_{\hat{\pi}} \) is a subalgebra of \( U(\hat{\varnothing}) \subseteq U(\hat{g}) \). Let

\[
\theta : U(\hat{\varnothing}) \hookrightarrow U(g)
\]

be the embedding sending \( e_{i,j} \in \hat{\varnothing} \) to \( e'_{i,j} \in g \) if the \( i \)-th and \( j \)-th boxes of \( \hat{\pi} \) correspond to the \( i' \)-th and \( j' \)-th boxes of \( \pi \), respectively. Let \( b \) be the label of
the box at the end of the second row of \( \pi \), i.e., the box that gets removed when passing from \( \pi \) to \( \hat{\pi} \). Also in the case that \( s_{1,2} = 1 \), let \( c \) be the label of the box at the end of the first row of \( \pi \).

**Lemma 5.2.** In the above notation, the following hold:

(i) \( t_{1,1;0}^{(r)} = \theta(t_{1,1;0}^{(r)}) \) for all \( r > 0 \),

(ii) \( t_{2,1;1}^{(r)} = \theta(t_{2,1;1}^{(r)}) \) for all \( r > s_{2,1} \),

(iii) \( t_{1,2;1}^{(r)} = \theta(t_{1,2;1}^{(r)}) + \theta(t_{1,2;1}^{(r-1)})S_{\hat{\rho}}(\tilde{e}_{b,b}) - [\theta(t_{1,2;1}^{(r-1)}), e_{b-1,b}] \) for all \( r > s_{1,2} \)

(iv) \( t_{2,2;1}^{(r)} = \theta(t_{2,2;1}^{(r)}) + \theta(t_{2,2;1}^{(r-1)})S_{\hat{\rho}}(\tilde{e}_{b,b}) - [\theta(t_{2,2;1}^{(r-1)}), e_{b-1,b}] \) for all \( r > 0 \).

**Proof.** This follows directly from the definition of these elements using also that \( \theta \circ S_{\hat{\rho}} = S_{\hat{\rho}} \circ \theta \) on elements of \( U(\hat{\mathfrak{p}}) \). \( \square \)

Observe next that \( m \) is generated by \( \theta(m) \cup J \), where

\[
J := \begin{cases} 
\{e_{b,c}, e_{b,b-1}\} & \text{if } s_{1,2} = 1, \\
\{e_{b,b-1}\} & \text{if } s_{1,2} > 1. 
\end{cases} \tag{5-3}
\]

We know by induction that the following elements of \( U(\hat{\mathfrak{p}}) \) belong to \( W_{\hat{\pi}} \): all \( t_{1,1;0}^{(r)} \) and \( t_{2,2;1}^{(r)} \) for \( r \geq 0 \), all \( t_{1,2;1}^{(r)} \) for \( r \geq s_{1,2} \) and all \( t_{2,2;1}^{(r)} \) for \( r > s_{2,1} \). Also note that the elements of \( \theta(m) \) commute with \( e_{b-1,b} \) and \( S_{\hat{\rho}}(\tilde{e}_{b,b}) \). Combined with Lemma 5.2, we deduce that \( [\theta(x), u] \in \theta(m_{\hat{\chi}})U(g) \subseteq m_{\hat{\chi}}U(g) \) for any \( x \in m \) and \( u \in \Omega \). It remains to show that \( [x, u] \in m_{\hat{\chi}}U(g) \) for each \( x \in J \) and \( u \in \Omega \). This is done in Lemmas 5.3, 5.4 and 5.6 below.

**Lemma 5.3.** For \( x \in J \) and \( u \in \{t_{1,1;0}^{(r)} \mid r > 0\} \cup \{t_{2,2;1}^{(r)} \mid r > s_{2,1}\} \), we have that \( [x, u] \in m_{\hat{\chi}}U(g) \).

**Proof.** Take \( e_{b,d} \in J \). Consider a monomial \( S_{\hat{\rho}}(\tilde{e}_{i_1,j_1} \cdots \tilde{e}_{i_h,j_h}) \) in the expansion of \( u \) from (4-10). The only way it could fail to supercommute with \( e_{b,d} \) is if it involves some \( \tilde{e}_{i_h,j_h} \) with \( j_h = b \) or \( i_h = d \). Since \( \text{row}(j_h) = 1 \) and \( \text{col}(i_h+1) > \text{col}(j_h) \) when \( \text{row}(j_h) = 2 \), this situation arises only if \( s_{1,2} = 1 \), \( i_h = d \) and \( j_h = c \). Then the supercommutator \( [e_{b,d}, \tilde{e}_{i_h,j_h}] \) equals \( \pm e_{b,c} \). It remains to repeat this argument to see that we can move the resulting \( e_{b,c} \in m_{\hat{\chi}} \) to the beginning. \( \square \)

It is harder to deal with the remaining elements \( t_{1,2;1}^{(r)} \) and \( t_{2,2;1}^{(r)} \) of \( \Omega \). We follow different approaches according to whether \( s_{1,2} > 1 \) or \( s_{1,2} = 1 \).

**Lemma 5.4.** Assume that \( s_{1,2} > 1 \). We have that \( [e_{b,b-1}, u] \in m_{\hat{\chi}}U(g) \) for all \( u \in \{t_{1,2;1}^{(r)} \mid r > s_{1,2}\} \cup \{t_{2,2;1}^{(r)} \mid r > 0\} \).

**Proof.** We just explain in detail for \( u = t_{1,2;1}^{(r)} \); the other case follows the same pattern. Let \( \check{\pi} \) be the pyramid obtained from \( \pi \) by removing its rightmost two columns. We
We combine this with Lemma 5.2(iii) to deduce for $r$ that

$$\phi : U(\mathfrak{g}) \hookrightarrow U(\mathfrak{g})$$

be the embedding sending $e_{i,j} \in \mathfrak{g}$ to $e_{i',j'} \in \mathfrak{g}$, where the $i$-th and $j$-th boxes of $\mathfrak{g}$ are labeled by $i$ and $j$ in $\pi$, respectively. For $r \geq s_{1,2}$, we have by analogy with Lemma 5.2(iii) that

$$\theta(i_{1,2;1}^{(r)}) = \phi(i_{1,2;1}^{(r)}) + \phi(i_{1,2;1}^{(r-1)})S_\tilde{\rho}(\tilde{e}_{b-1,b-1}) - [\phi(i_{1,2;1}^{(r-1)}), e_{b-2,b-1}]$$

We combine this with Lemma 5.2(iii) to deduce for $r > s_{1,2}$ that

$$t_{1,2;1}^{(r)} = \phi(i_{1,2;1}^{(r)}) + \phi(i_{1,2;1}^{(r-1)})S_\tilde{\rho}(\tilde{e}_{b-1,b-1}) - [\phi(i_{1,2;1}^{(r-1)}), e_{b-2,b-1}]
+ \phi(i_{1,2;1}^{(r-1)})S_\tilde{\rho}(\tilde{e}_{b,b}) + \phi(i_{1,2;1}^{(r-2)})S_\tilde{\rho}(\tilde{e}_{b-1,b-1})S_\tilde{\rho}(\tilde{e}_{b,b})
- [\phi(i_{1,2;1}^{(r-2)}), e_{b-2,b-1}]S_\tilde{\rho}(\tilde{e}_{b,b}) - \phi(i_{1,2;1}^{(r-2)})\tilde{e}_{b-1,b} + [\phi(i_{1,2;1}^{(r-2)}), e_{b-2,b}]$$

We deduce that

$$[e_{b,b-1}, t_{1,2;1}^{(r)}] = \phi(i_{1,2;1}^{(r-2)})\tilde{e}_{b,b-1}S_\tilde{\rho}(\tilde{e}_{b,b}) - \tilde{e}_{b,b-1}S_\tilde{\rho}(\tilde{e}_{b-1,b-1}) + (-1)^{|2|}\tilde{e}_{b,b-1}
+ [\phi(i_{1,2;1}^{(r-2)}), e_{b-2,b-1}]\tilde{e}_{b,b-1} - \phi(i_{1,2;1}^{(r-2)})(\tilde{e}_{b,b} - \tilde{e}_{b-1,b-1}) - [\phi(i_{1,2;1}^{(r-2)}), e_{b-2,b-1}]$$

Working modulo $m_{\chi}U(\mathfrak{g})$, we can replace all $\tilde{e}_{b,b-1}$ by 1. Then we are reduced just to checking that

$$S_\tilde{\rho}(\tilde{e}_{b,b}) - S_\tilde{\rho}(\tilde{e}_{b-1,b-1}) + (-1)^{|2|} = \tilde{e}_{b,b} - \tilde{e}_{b-1,b-1}.$$  

This follows because $(\tilde{\rho}|_{\mathfrak{e}_{b}}) - (\tilde{\rho}|_{\mathfrak{e}_{b-1}}) + (-1)^{|2|} = 0$ by the definition (4-8). \qed

**Lemma 5.5.** Assume that $s_{1,2} = 1$. For $r > 2$, we have that

$$t_{1,2;1}^{(r)} = (-1)^{|1|}[t_{1,1;0}^{(2)}, t_{1,2;1}^{(r-1)}] - t_{1,1;0}^{(1)}t_{1,2;1}^{(r-1)}, \quad (5-4)$$

$$t_{2,2;1}^{(r)} = (-1)^{|1|}[t_{1,2;1}^{(2)}, t_{2,2;1}^{(r-1)}] - \sum_{a=0}^{r} t_{1,1;1}^{(a)}t_{2,2;1}^{(r-a)} \quad (5-5)$$

**Proof.** We prove (5-4). The induction hypothesis means that we can appeal to Theorem 4.5 for the algebra $W_{\tilde{\chi}}$. Hence, using the relations from Theorem 2.2, we know that the following holds in the algebra $W_{\tilde{\chi}}$ for all $r \geq 2$:

$$i_{1,2;1}^{(r)} = (-1)^{|1|}[i_{1,1;0}^{(2)}, i_{1,2;1}^{(r-1)}] - t_{1,1;0}^{(1)}i_{1,2;1}^{(r-1)}.$$
Using Lemma 5.2, we deduce for \( r > 2 \) that
\[
\begin{align*}
t_{1,2;1}^{(r)} &= \theta(i_{1,2;1}^{(r)}) + \theta(i_{1,2;1}^{(r-1)}) S_{\tilde{\rho}}(\tilde{e}_{b,b}) - [\theta(i_{1,2;1}^{(r-1)}), e_{b-1,b}] \\
&= (-1)^{1\varepsilon} \left[ t_{1,1;0}^{(2)}, \theta(i_{1,2;1}^{(r-1)}) \right] - t_{1,1;0}^{(1)} \theta(i_{1,2;1}^{(r-1)}) \\
&\quad + (-1)^{1\varepsilon} \left[ t_{1,1;0}, \theta(i_{1,2;1}^{(r-2)}) \right] S_{\tilde{\rho}}(\tilde{e}_{b,b}) - t_{1,1;0}^{(1)} \theta(i_{1,2;1}^{(r-2)}) S_{\tilde{\rho}}(\tilde{e}_{b,b}) \\
&\quad - (-1)^{1\varepsilon} \left[ t_{1,1;0}, \theta(i_{1,2;1}^{(r-2)}) \right] S_{\tilde{\rho}}(\tilde{e}_{b,b}) - t_{1,1;0}^{(1)} \theta(i_{1,2;1}^{(r-2)}) S_{\tilde{\rho}}(\tilde{e}_{b,b})
\end{align*}
\]

The other equation (5-5) follows by a similar trick. \( \square \)

**Lemma 5.6.** Assume that \( s_{1,2} = 1 \). We have that \([x, u] \in m_{\chi} U(g)\) for all \( x \in J \) and \( u \in \{ t_{1,2;1}^{(r)} \mid r > s_{1,2} \} \cup \{ t_{1,2;1}^{(r)} \mid r > 0 \} \).

**Proof.** Proceed by induction on \( r \). The base cases when \( r \leq 2 \) are small enough that they can be checked directly from the definitions. Then for \( r > 2 \), use Lemma 5.5, noting by the induction hypothesis and Lemma 5.3 that all the terms on the right-hand side of (5-4) and (5-5) are already known to lie in \( m_{\chi} U(g) \). \( \square \)

We have now verified the induction step in the case that \( s_{1,2} \geq s_{2,1} \). It remains to establish the induction step when \( s_{2,1} > s_{1,2} \). The strategy for this is sufficiently similar to the case just done (based on removing columns from the left of the pyramid \( \pi \)) that we leave the details to the reader. We just note one minor difference: in the proof of the analogue of Lemma 5.2, it is no longer the case that \( \theta \circ S_{\tilde{\rho}} = S_{\tilde{\rho}} \circ \theta \), but this can be fixed by allowing the choice of \( \tilde{\rho} \) to change by a multiple of \( \varepsilon_1 + \cdots + \varepsilon_m - \varepsilon_{m+1} - \cdots - \varepsilon_{m+n} \).

This completes the proof of Proposition 4.4. \( \square \)

### 6. Triangular decomposition

Let \( W_{\pi} \) be the principal \( W \)-algebra in \( g = gl_{m|n}(\mathbb{C}) \) associated to pyramid \( \pi \). We adopt all the notation from §4. So

- \( (|1|, |2|) \) is a parity sequence chosen so that \( (|1|, |2|) = (\tilde{\varepsilon}, \tilde{I}) \) if \( m < n \) and \( (|1|, |2|) = (\tilde{I}, \tilde{\varepsilon}) \) if \( m > n \),
- \( \pi \) has \( k = \min(m, n) \) boxes in its first row and \( l = \max(m, n) \) boxes in its second row and
- \( \sigma = (s_{i,j})_{1 \leq i, j \leq 2} \) is a shift matrix compatible with \( \pi \).

We identify \( W_{\pi} \) with \( Y_{\sigma}^l \), the shifted Yangian of level \( l \), via the isomorphism \( \mu \) from (4-18). Thus, we have available a set of Drinfeld generators for \( W_{\pi} \) satisfying
the relations from Theorem 2.2 plus the additional truncation relations $d_{i}^{(r)} = 0$ for $r > k$. In view of (4-19)–(4-21) and (4-10), we even have available explicit formulae for these generators as elements of $U(p)$ although we seldom need to use these (but see the proof of Lemma 8.3 below).

By the relations, $W_{\pi}$ admits a $\mathbb{Z}$-grading

$$W_{\pi} = \bigoplus_{g \in \mathbb{Z}} W_{\pi;g}$$

such that the generators $d_{i}^{(r)}$ are of degree 0, the generators $e^{(r)}$ are of degree 1 and the generators $f^{(r)}$ are of degree $-1$. Moreover, the PBW theorem (Corollary 3.6) implies that $W_{\pi;g} = 0$ for $|g| > k$.

More surprisingly, the algebra $W_{\pi}$ admits a triangular decomposition. To introduce this, let $W_{\pi}^{0}$, $W_{\pi}^{+}$ and $W_{\pi}^{-}$ be the subalgebras of $W_{\pi}$ generated by the elements $\Omega_{0} := \{d_{i}^{(r)}, d_{2}^{(s)} \mid 0 < r \leq k, 0 < s \leq l\}$, $\Omega_{+} := \{e^{(r)} \mid s_{1,2} < r \leq s_{1,2} + k\}$ and $\Omega_{-} := \{f^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k\}$, respectively. Let $W_{\pi}^{=} \text{ and } W_{\pi}^{\flat}$ be the subalgebras of $W_{\pi}$ generated by $\Omega_{0} \cup \Omega_{+}$ and $\Omega_{-} \cup \Omega_{0}$, respectively. We warn the reader that the elements $e^{(r)}$ ($r > s_{1,2} + k$) do not necessarily lie in $W_{\pi}^{+}$ (but they do lie in $W_{\pi}^{\flat}$ by (3-5)). Similarly, the elements $f^{(r)}$ for $r > s_{2,1} + k$ do not necessarily lie in $W_{\pi}^{-}$ (but they do lie in $W_{\pi}^{\flat}$), and the elements $d_{2}^{(r)}$ for $r > l$ do not necessarily lie in any of $W_{\pi}^{0}$, $W_{\pi}^{=} \text{ or } W_{\pi}^{\flat}$.

**Theorem 6.1.** The algebras $W_{\pi}^{0}$, $W_{\pi}^{+}$ and $W_{\pi}^{-}$ are free supercommutative superalgebras on generators $\Omega_{0}$, $\Omega_{+}$ and $\Omega_{-}$, respectively. Multiplication defines vector space isomorphisms

$$W_{\pi}^{-} \otimes W_{\pi}^{0} \otimes W_{\pi}^{+} \sim W_{\pi}, \quad W_{\pi}^{0} \otimes W_{\pi}^{+} \sim W_{\pi}^{=}, \quad W_{\pi}^{-} \otimes W_{\pi}^{0} \sim W_{\pi}^{\flat}.$$

Moreover, there are unique surjective homomorphisms

$$W_{\pi}^{=} \rightarrow W_{\pi}^{0}, \quad W_{\pi}^{\flat} \rightarrow W_{\pi}^{0}$$

sending $e^{(r)} \mapsto 0$ for all $r > s_{1,2}$ or $f^{(r)} \mapsto 0$ for all $r > s_{2,1}$, respectively, such that the restriction of these maps to the subalgebra $W_{\pi}^{0}$ is the identity.

**Proof.** Throughout the proof, we repeatedly apply the PBW theorem (Corollary 3.6), choosing the order of generators so that $\Omega_{-} < \Omega_{0} < \Omega_{+}$.

To start with, note by the left-hand relations in Theorem 2.2 that each of $W_{\pi}^{0}$, $W_{\pi}^{+}$ and $W_{\pi}^{-}$ is supercommutative. Combined with the PBW theorem, we deduce that they are free supercommutative on the given generators. Moreover, the PBW theorem implies that the multiplication map $W_{\pi}^{-} \otimes W_{\pi}^{0} \otimes W_{\pi}^{+} \rightarrow W_{\pi}$ is a vector space isomorphism.

Next we observe that $W_{\pi}^{=}$ contains all the elements $e^{(r)}$ for $r > s_{1,2}$. This follows from (3-5) by induction on $r$. Moreover, it is spanned as a vector space by the ordered supernomials in the generators $\Omega_{0} \cup \Omega_{+}$. This follows from (3-5), the relation for $[d_{i}^{(r)}, e^{(s)}]$ in Theorem 2.2 and induction on Kazhdan degree. Hence,
the multiplication map $W^0_\pi \otimes W^+_\pi \rightarrow W^0_\pi$ is surjective. It is injective by the PBW theorem, so it is an isomorphism. Similarly, $W^-_\pi \otimes W^0_\pi \rightarrow W^0_\pi$ is an isomorphism.

Finally, let $J^\pi$ be the two-sided ideal of $W^\pi$ that is the sum of all of the graded components $W^\pi_{g}:={W^\pi_1 \cap W^\pi_2}$ for $g > 0$. By the PBW theorem, the natural quotient map $W^0_\pi \rightarrow W^\pi_0 / J^\pi$ is an isomorphism. Hence, there is a surjection $W^\pi_0 \rightarrow W^\pi_0$ as in the statement of the theorem. A similar argument yields the desired surjection $W^0_\pi \rightarrow W^0_\pi$. \qed

7. Irreducible representations

Continue with the notation of Section 6. Using the triangular decomposition, we can classify irreducible $W_\pi$-modules by highest weight theory. Define a $\pi$-tableau to be a filling of the boxes of the pyramid $\pi$ by arbitrary complex numbers. Let $\text{Tab}_\pi$ denote the set of all such $\pi$-tableaux. We represent the $\pi$-tableau with entries $a_1, \ldots, a_k$ along its first row and $b_1, \ldots, b_l$ along its second row simply by the array $(a_1, \ldots, a_k, b_1, \ldots, b_l)$. We say that $A, B \in \text{Tab}_\pi$ are row equivalent, denoted $A \sim B$, if $B$ can be obtained from $A$ by permuting entries within each row.

Recall from Theorem 6.1 that $W^0_\pi$ is the polynomial algebra on

$$\{d^{(r)}_1, d^{(s)}_2 \mid 0 < r \leq k, \ 0 < s \leq l\}.$$ 

For $A = (a_1, \ldots, a_k) \in \text{Tab}_\pi$, let $C_A$ be the one-dimensional $W^0_\pi$-module on basis $1_A$ such that

$$u^k d^{(r)}_1 (u) 1_A = (u + a_1) \cdots (u + a_k) 1_A, \quad (7-1)$$

$$u^l d^{(s)}_2 (u) 1_A = (u + b_1) \cdots (u + b_l) 1_A. \quad (7-2)$$

Thus, $d^{(r)}_1 1_A = e_r (a_1, \ldots, a_k) 1_A$ and $d^{(r)}_2 1_A = e_r (b_1, \ldots, b_l) 1_A$, where $e_r$ denotes the $r$-th elementary symmetric polynomial. Every irreducible $W^0_\pi$-module is isomorphic to $C_A$ for some $A \in \text{Tab}_\pi$, and $C_A \cong C_B$ if and only if $A \sim B$.

Given $A \in \text{Tab}_\pi$, we view $C_A$ as a $W^\pi_0$-module via the surjection $W^\pi_0 \rightarrow W^0_\pi$ from Theorem 6.1, i.e., $e^{(r)} 1_A = 0$ for all $r > s_{1,2}$. Then we induce to form the Verma module

$$\overline{M}(A) := W_\pi \otimes_{W^\pi_0} C_A.$$ \quad (7-3)

Sometimes we need to view this as a supermodule, which we do by declaring that its cyclic generator $1 \otimes 1_A$ is even. By Theorem 6.1, $W_\pi$ is a free right $W^\pi_0$-module with basis given by the ordered supermonomials in the odd elements $\{f^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k\}$. Hence, $\overline{M}(A)$ has basis given by the vectors $x \otimes 1_A$ as $x$ runs over this set of supermonomials. In particular, $\dim \overline{M}(A) = 2^k$.

The following lemma shows that $\overline{M}(A)$ has a unique irreducible quotient, which we denote by $\overline{L}(A)$; we write $v_+$ for the image of $1 \otimes 1_A$ in $\overline{M}(A)$ in $\overline{L}(A)$. 

Lemma 7.1. For $A = \sum_{i=1}^{k} a_i b_i \in \text{Tab}_\pi$, the Verma module $\overline{M}(A)$ has a unique irreducible quotient $\overline{L}(A)$. The image $v_+$ of $1 \otimes 1_A$ is the unique (up to scalars) nonzero vector in $\overline{L}(A)$ such that $e^r v_+ = 0$ for all $r > s_{1,2}$. Moreover, we have that $d_1^{(r)} v_+ = e_i(a_1, \ldots, a_k) v_+$ and $d_2^{(r)} v_+ = e_r(b_1, \ldots, b_l) v_+$ for all $r \geq 0$.

Proof. Let $\lambda := (-1)^{|1|}(a_1 + \cdots + a_k)$. For any $\mu \in \mathbb{C}$, let $\overline{M}(A)_\mu$ be the $\mu$-eigenspace of the endomorphism of $\overline{M}(A)$ defined by $d := (-1)^{|1|}d_1^{(1)} \in W_\pi$. Note by (7-1) and the relations that $d 1_A = \lambda 1_A$ and $[d, f^{(r)}] = -f^{(r)}$ for each $r > s_{2,1}$. Using the PBW basis for $\overline{M}(A)$, it follows that

$$\overline{M}(A) = \bigoplus_{i=0}^{k} \overline{M}(A)_{\lambda - i}$$

and $\dim \overline{M}(A)_{\lambda - i} = (k)$ for each $0 \leq i \leq k$. In particular, $\overline{M}(A)_\lambda$ is one-dimensional, and it generates $\overline{M}(A)$ as a $W_\pi^\circ$-module. This is all that is needed to deduce that $\overline{M}(A)$ has a unique irreducible quotient $\overline{L}(A)$ following the standard argument of highest weight theory.

The vector $v_+$ is a nonzero vector annihilated by $e^r$ for $r > s_{1,2}$, and $d_1^{(r)} v_+$ and $d_2^{(r)} v_+$ are as stated thanks to (7-1) and (7-2). It just remains to show that any vector $v \in \overline{L}(A)$ annihilated by all $e^r$ is a multiple of $v_+$. The decomposition (7-4) induces an analogous decomposition

$$\overline{L}(A) = \bigoplus_{i=0}^{k} \overline{L}(A)_{\lambda - i}$$

although for $0 < i \leq k$ the eigenspace $\overline{L}(A)_{\lambda - i}$ may now be 0. Write $v = \sum_{i=0}^{k} v_i$ with $v_i \in \overline{L}(A)_{\lambda - i}$. Then we need to show that $v_i = 0$ for $i > 0$. We have that $e^{(r)} v = \sum_{i=1}^{k} e^{(r)} v_i = 0$; hence, $e^{(r)} v_i = 0$ for each $i$. But this means for $i > 0$ that the submodule $W_\pi v_i = W_\pi v_i$ has trivial intersection with $\overline{L}(A)_\lambda$, so it must be 0. □

Here is the classification of irreducible $W_\pi$-modules.

Theorem 7.2. Every irreducible $W_\pi$-module is finite-dimensional and is isomorphic to one of the modules $\overline{L}(A)$ from Lemma 7.1 for some $A \in \text{Tab}_\pi$. Moreover, $\overline{L}(A) \cong \overline{L}(B)$ if and only if $A \sim B$. Hence, fixing a set $\text{Tab}_\pi / \sim$ of representatives for the $\sim$-equivalence classes in $\text{Tab}_\pi$, the modules

$$\{\overline{L}(A) \mid A \in \text{Tab}_\pi / \sim\}$$

give a complete set of pairwise inequivalent irreducible $W_\pi$-modules.

Proof. We note, to start with, for $A, B \in \text{Tab}_\pi$ that $\overline{L}(A) \cong \overline{L}(B)$ if and only if $A \sim B$. This is clear from Lemma 7.1.
Now take an arbitrary (conceivably infinite-dimensional) irreducible \( W_\pi \)-module \( L \). We want to show that \( L \cong \overline{L}(A) \) for some \( A \in \text{Tab}_\pi \). For \( i \geq 0 \), let

\[ L[i] := \{ v \in L \mid W_\pi; g v = 0 \text{ if } g > 0 \text{ or } g \leq -i \}. \]

We claim initially that \( L[k + 1] \neq \{0\} \). To see this, recall that \( W_\pi; g = \{0\} \) for \( g \leq -k - 1 \), so by the PBW theorem, \( L[k + 1] \) is simply the set of all vectors \( v \in L \) such that \( e^{(r)} v = 0 \) for all \( s_{1,2} < r \leq s_{1,2} + k \). Now take any nonzero vector \( v \in L \) such that \( \#\{r = s_{1,2} + 1, \ldots, s_{1,2} + k \mid e^{(r)} v = 0 \} \) is maximal. If \( e^{(r)} v \neq 0 \) for some \( s_{1,2} < r \leq s_{1,2} + k \), we can replace \( v \) by \( e^{(r)} v \) to get a nonzero vector annihilated by more \( e^{(r)} \)'s. Hence, \( v \in L[k + 1] \) by the maximality of the choice of \( v \), and we have shown that \( L[k + 1] \neq \{0\} \).

Since \( L[k + 1] \neq \{0\} \), it makes sense to define \( i \geq 0 \) to be minimal such that \( L[i] \neq \{0\} \). Since \( L[0] = \{0\} \), we actually have that \( i > 0 \). Pick \( 0 \neq v \in L[i] \), and let \( L' := W_\pi^0 v \). Actually, by the PBW theorem, we have that \( L' = W_\pi^0 v \) and \( L' \subseteq L[i] \).

Suppose first that \( L' \) is irreducible as a \( W_\pi^0 \)-module. Then \( L' \cong C_A \) for some \( A \in \text{Tab}_\pi \). The inclusion \( L' \hookrightarrow L \) induces a nonzero \( W_\pi \)-module homomorphism

\[ \overline{M}(A) \cong W_\pi \otimes_{W_\pi^0} L' \to L, \]

which is surjective as \( L \) is irreducible. Hence, \( L \cong \overline{L}(A) \).

It remains to rule out the possibility that \( L' \) is reducible. Suppose for a contradiction that \( L' \) possesses a nonzero proper \( W_\pi^0 \)-submodule \( L'' \). As \( L = W_\pi L'' \) and \( W_\pi^0 L'' = L'' \), the PBW theorem implies that we can write

\[ v = w + \sum_{h=1}^{k} \sum_{s_{2,1} < r_1 < \cdots < r_h \leq s_{2,1} + k} f^{(r_1)} \cdots f^{(r_h)} v_{r_1, \ldots, r_h} \]

for some vectors \( v_{r_1, \ldots, r_h}, w \in L'' \). Then we have that

\[ 0 \neq v - w \in L[i] \cap \left( \sum_{g \leq -1} W_\pi; g L[i] \right) \subseteq L[i - 1]. \]

This shows \( L[i - 1] \neq \{0\} \), contradicting the minimality of the choice of \( i \).

The final theorem of the section gives an explicit monomial basis for \( \overline{L}(A) \). We only prove linear independence here; the spanning part of the argument will be given in Section 8.

**Theorem 7.3.** Suppose \( A = a_1 b_1 \cdots a_h b_h \in \text{Tab}_\pi \). Let \( h \geq 0 \) be maximal such that there exist distinct \( 1 \leq i_1, \ldots, i_h \leq k \) and distinct \( 1 \leq j_1, \ldots, j_h \leq l \) with \( a_{i_1} = b_{j_1}, \ldots, a_{i_h} = b_{j_h} \).

Then the irreducible module \( \overline{L}(A) \) has basis given by the vectors \( xv_+ \) as \( x \) runs over all ordered supermonomials in the odd elements \( \{ f^{(r)} \mid s_{2,1} < r \leq s_{2,1} + k - h \} \).
We proceed to show that the vectors \( x v_+ \) for all ordered supermonomials \( x \) in \( \{ f(r) \mid s_{2,1} < r \leq s_{2,1} + \bar{k} \} \) are linearly independent in \( \bar{L}(A) \). In fact, it is enough for this to show just that
\[
f^{(s_{2,1}+1)} f^{(s_{2,1}+2)} \cdots f^{(s_{2,1}+\bar{k})} v_+ \neq 0. \tag{7-6}
\]
Indeed, assuming (7-6), we can prove the linear independence in general by taking any nontrivial linear relation of the form
\[
\sum_{a=0}^{\bar{k}} \sum_{s_{2,1}<r_1<\cdots<r_a \leq s_{2,1}+\bar{k}} \lambda_{r_1,\ldots,r_a} f^{(r_1)} \cdots f^{(r_a)} v_+ = 0.
\]
Let \( a \) be minimal such that \( \lambda_{r_1,\ldots,r_a} \neq 0 \) for some \( r_1, \ldots, r_a \). Apply \( f^{(s_1)} \cdots f^{(s_{\bar{k}-a})} \), where \( s_{2,1} < s_1 < \cdots < s_{\bar{k}-a} \leq s_{2,1} + \bar{k} \) are different from \( r_1 < \cdots < r_a \). All but one term of the summation becomes 0, and using (7-6), we can deduce that \( \lambda_{r_1,\ldots,r_a} = 0 \), a contradiction.

In this paragraph, we prove (7-6) by showing that
\[
e^{(s_{1,2}+1)} e^{(s_{1,2}+2)} \cdots e^{(s_{1,2}+\bar{k})} f^{(s_{2,1}+1)} f^{(s_{2,1}+2)} \cdots f^{(s_{2,1}+\bar{k})} v_+ \neq 0. \tag{7-7}
\]
The left-hand side of (7-7) equals
\[
\sum_{w \in S_{\bar{k}}} \text{sgn}(w)[ e^{(\bar{k}+1+s_{1,2}-1)} f^{(s_{2,1}+w(1))} ] \cdots [ e^{(\bar{k}+1+s_{1,2}-\bar{k})} f^{(s_{2,1}+w(\bar{k}))} ] v_+.
\]
By Remark 2.3, up to a sign, this is \( \det(e^{(j-i+i)})_{1 \leq i, j \leq \bar{k}} v_+ \). It is easy to see from Lemma 7.1 that \( e^{(r)} v_+ = e_r(b_1, \ldots, b_l/a_1, \ldots, a_{\bar{k}}) v_+ \), where
\[
e_r(b_1, \ldots, b_l/a_1, \ldots, a_{\bar{k}}) := \sum_{s+t=r} (-1)^t e_s(b_1, \ldots, b_l) h_t(a_1, \ldots, a_{\bar{k}})
\]
is the \( r \)-th elementary supersymmetric function from [Macdonald 1995, Exercise I.3.23]. Thus, we need to show that \( \det(e_{i-i+j}(b_1, \ldots, b_l/a_1, \ldots, a_{\bar{k}}))_{1 \leq i, j \leq \bar{k}} \neq 0 \). But this determinant is the supersymmetric Schur function \( s_\lambda(b_1, \ldots, b_l/a_1, \ldots, a_{\bar{k}}) \) for the partition \( \lambda = (\bar{k}) \) defined in [Macdonald 1995, Exercise I.3.23]. Hence, by the factorization property described there, it is equal to \( \prod_{1 \leq i \leq l} \prod_{1 \leq j \leq \bar{k}} (b_i - a_j) \), which is indeed nonzero.

We have now proved the linear independence of the vectors \( x v_+ \) as \( x \) runs over all ordered supermonomials in \( \{ f(r) \mid s_{2,1} < r \leq s_{2,1} + \bar{k} \} \). It remains to show that these vectors also span \( \bar{L}(A) \). For this, it is enough to show that \( \dim \bar{L}(A) \leq 2^{\bar{k}} \). This will be established in the next section by means of an explicit construction of a module of dimension \( 2^{\bar{k}} \) containing \( \bar{L}(A) \) as a subquotient. \( \square \)
In this section, we define some more general comultiplications between the algebras $W_\pi$, allowing certain tensor products to be defined. We apply this to construct so-called standard modules $\overline{V}(A)$ for each $A \in \text{Tab}_\pi$. Then we complete the proof of Theorem 7.3 by showing that every irreducible $W_\pi$-module is isomorphic to one of the modules $\overline{V}(A)$ for suitable $A$.

Recall that the pyramid $\pi$ has $l$ boxes on its second row. Suppose we are given $l_1, \ldots, l_d \geq 0$ such that $l_1 + \cdots + l_d = l$. For each $c = 1, \ldots, d$, let $\pi_c$ be the pyramid consisting of columns $l_1 + \cdots + l_{c-1} + 1, \ldots, l_1 + \cdots + l_c$ of $\pi$. Thus, $\pi$ is the “concatenation” of the pyramids $\pi_1, \ldots, \pi_d$. Let $W_\pi$ be the principal $W$-algebra defined from $\pi_c$. Let $\sigma_1, \ldots, \sigma_d$ be the unique shift matrices such that each $\sigma_c$ is compatible with $\pi_c$ and $\sigma_c$ is lower or upper triangular if $s_{2,1} \geq l_1 + \cdots + l_c$ or $s_{1,2} \geq l_1 + \cdots + l_d$, respectively. We denote the Miura transform for $W_\pi$ by $\mu_c : W_\pi \hookrightarrow U_{\sigma_c}^{l_c}$.

**Lemma 8.1.** With the above notation, there is a unique injective algebra homomorphism

$$\Delta_{l_1, \ldots, l_d} : W_\pi \hookrightarrow W_{\pi_1} \otimes \cdots \otimes W_{\pi_d}$$

such that $(\mu_1 \otimes \cdots \otimes \mu_d) \circ \Delta_{l_1, \ldots, l_d} = \mu$.

**Proof.** Let us add the suffix $c$ to all notation arising from the definition of $W_\pi$ so that $W_{\pi_c}$ is a subalgebra of $U(\mathfrak{p}_c)$, we have that $\mathfrak{g}_c = \mathfrak{m}_c \oplus \mathfrak{h}_c \oplus \mathfrak{p}_c^\perp$ and so on. We identify $\mathfrak{g}_1 \oplus \cdots \oplus \mathfrak{g}_d$ with a subalgebra $\mathfrak{g}'$ of $\mathfrak{g}$ so that $e_{i,j} \in \mathfrak{g}_c$ is identified with $e_{i',j'} \in \mathfrak{g}'$, where $i'$ and $j'$ are the labels of the boxes of $\pi$ corresponding to the $i$-th and $j$-th boxes of $\pi_c$, respectively. Similarly, we identify $\mathfrak{m}_1 \oplus \cdots \oplus \mathfrak{m}_d$ with $\mathfrak{m}' \subseteq \mathfrak{m}$, $\mathfrak{p}_1 \oplus \cdots \oplus \mathfrak{p}_d$ with $\mathfrak{p}' \subseteq \mathfrak{p}$ and $\mathfrak{h}_1 \oplus \cdots \oplus \mathfrak{h}_d$ with $\mathfrak{h}' = \mathfrak{h}$. Also let $\tilde{\rho}' := \tilde{\rho}_1 + \cdots + \tilde{\rho}_d$, a character of $\mathfrak{p}'$. In this way, $W_{\pi_1} \otimes \cdots \otimes W_{\pi_d}$ is identified with $W'_{\pi} := \{u \in U(\mathfrak{p}') \mid um'_{\chi} \subseteq m'_{\chi} U(\mathfrak{g}')\}$, where $m'_{\chi} = \{x - \chi(x) \mid x \in m'\}$.

Let $q$ be the unique parabolic subalgebra of $\mathfrak{g}$ with Levi factor $\mathfrak{g}'$ such that $p \subseteq q$. Let $\psi : U(q) \twoheadrightarrow U(q')$ be the homomorphism induced by the natural projection of $q \twoheadrightarrow \mathfrak{g}'$. The following diagram commutes:

$$\begin{array}{ccc}
U(\mathfrak{p}) & \xrightarrow{S_{-\tilde{\rho}'(\psi \circ S_{\tilde{\rho}})}} & U(\mathfrak{p}') \\
pr \circ S_{\tilde{\rho}} & & pr' \circ S_{\tilde{\rho}'} \\
U(\mathfrak{h}) & \xrightarrow{U(\tilde{\rho}'(\psi \circ S_{\tilde{\rho}}))} & U(\mathfrak{h}')
\end{array}$$

We claim that $S_{-\tilde{\rho}'(\psi \circ S_{\tilde{\rho}})}$ maps $W_\pi$ into $W'_{\pi}$. The claim implies the lemma, for then it makes sense to define $\Delta_{l_1, \ldots, l_d}$ to be the restriction of this map to $W_\pi$, and we are done by the commutativity of the above diagram and injectivity of the Miura transform.
To prove the claim, observe that $\tilde{\rho} - \tilde{\rho}'$ extends to a character of $\frak{q}$; hence, there is a corresponding shift automorphism $S_{\tilde{\rho} - \tilde{\rho}'} : U(q) \to U(q)$ that preserves $W'_\pi$. Moreover, $S_{\tilde{\rho} - \tilde{\rho}'} \circ \psi \circ S_{\tilde{\rho}} = S_{\tilde{\rho} - \tilde{\rho}'} \circ \psi$. Therefore, it enough to check just that $\psi(W_\pi) \subseteq W'_\pi$. To see this, take $u \in W_\pi$ so that $um_{\chi} \subseteq m_\chi U(q)$. This implies that $um_{\chi}' \subseteq m_\chi U(g) \cap U(q)$; hence, applying $\psi$ we get that $\psi(u)m_{\chi}' \subseteq m_\chi U(g')$. This shows that $\psi(u) \in W'_\pi$ as required. \qed

**Remark 8.2.** Special cases of the maps (8-1) with $d = 2$ are related to the comultiplications $\Delta$, $\Delta_+$ and $\Delta_-$ from (2-14)–(2-16). Indeed, if $l = l_1 + l_2$ for $l_1 \geq s_{2,1}$ and $l_2 \geq s_{1,2}$, the shift matrices $\sigma_1$ and $\sigma_2$ above are equal to $\sigma^{lo}$ and $\sigma^{up}$, respectively. Both squares in the following diagram commute:

\[
\begin{array}{ccc}
Y_\sigma & \xrightarrow{\Delta} & Y_{\sigma_1} \otimes Y_{\sigma_2} \\
\downarrow{\text{ev}_\sigma} & & \downarrow{\text{ev}_{\sigma_1} \otimes \text{ev}_{\sigma_2}} \\
U_\sigma & \xrightarrow{U} & U_{\sigma_1} \otimes U_{\sigma_2} \\
\uparrow{\mu} & & \uparrow{\mu_1 \otimes \mu_2} \\
W_\pi & \xrightarrow{\Delta_{l_1,l_2}} & W_{\pi_1} \otimes W_{\pi_2}
\end{array}
\]

Indeed, the top square commutes by the definition of the evaluation homomorphisms from (3-2) while the bottom square commutes by Lemma 8.1. Hence, under our isomorphism between principal $W$-algebras and truncated shifted Yangians, $\Delta_{l_1,l_2} : W_\pi \to W_{\pi_1} \otimes W_{\pi_2}$ corresponds exactly to the map $Y_{\sigma} \to Y_{\sigma_1} \otimes Y_{\sigma_2}$ induced by the comultiplication $\Delta : Y_\sigma \to Y_{\sigma_1} \otimes Y_{\sigma_2}$.

Instead, if $l_1 = l - 1$, $l_2 = 1$ and the rightmost column of $\pi$ consists of a single box, the map $\Delta_{l-1,1} : W_\pi \to W_{\pi_1} \otimes U(\frak{gl}_1)$ corresponds exactly to the map $Y_\sigma \to Y_{\sigma_{l-1}} \otimes U(\frak{gl}_1)$ induced by $\Delta_+ : Y_\sigma \to Y_{\sigma_+} \otimes U(\frak{gl}_1)$. Similarly, if $l_1 = 1$, $l_2 = l - 1$ and the leftmost column of $\pi$ consists of a single box, $\Delta_{l-1,l} : W_\pi \to U(\frak{gl}_1) \otimes W_{\pi_2}$ corresponds exactly to the map $Y_{\sigma_{l-1}} \otimes Y_{\sigma_1} \to U(\frak{gl}_1) \otimes Y_{\sigma_-}$ induced by $\Delta_- : Y_\sigma \to U(\frak{gl}_1) \otimes Y_{\sigma_-}$.

Using (8-1), we can make sense of tensor products: if we are given $W_{\pi_c}$-modules $V_c$ for each $c = 1, \ldots, d$, then we obtain a well-defined $W_\pi$-module

\[
V_1 \otimes \cdots \otimes V_d := \Delta^*_{l_1,\ldots,l_d}(V_1 \boxtimes \cdots \boxtimes V_d),
\]

(8-2) i.e., we take the pull-back of their outer tensor product (viewed as a module via the usual sign convention).

Now specialize to the situation that $d = l$ and $l_1 = \cdots = l_d = 1$. Then each pyramid $\pi_c$ is a single column of height 1 or 2. In the former case, $W_{\pi_c} = U(\frak{gl}_1)$, and in the latter, $W_{\pi_c} = U(\frak{gl}_{1|1})$. So we have that $W_{\pi_1} \otimes \cdots \otimes W_{\pi_l} = U_{\sigma}$, and the map $\Delta_{1,\ldots,1}$ coincides with the Miura transform $\mu$. 
Given \( A \in \text{Tab}_\pi \), let \( A_c \in \text{Tab}_{\pi_c} \) be its \( c \)-th column and \( \overline{L}(A_c) \) be the corresponding irreducible \( W_{\pi_c} \)-module. Let us decode this notation a little. If \( W_{\pi_c} = U(\mathfrak{gl}_1) \), then \( A_c \) has just a single entry \( b \) and \( \overline{L}(A_c) \) is the one-dimensional module with an even basis vector \( v_+ \) such that \( e_{1,1}v_+ = (-1)^{2|b|}bv_+ \). If \( W_{\pi_c} = U(\mathfrak{gl}_{1|1}) \), then \( A_c \) has two entries, \( a \) in the first row and \( b \) in the second row, and \( \overline{L}(A_c) \) is one- or two-dimensional according to whether \( a = b \); in both cases \( \overline{L}(A_c) \) is generated by an even vector \( v_+ \) such that \( e_{1,1}v_+ = (-1)^{|a|}av_+, e_{2,2}v_+ = (-1)^{|2|}bv_+ \) and \( e_{1,2}v_+ = 0 \). Let \( \overline{V}(A) := \overline{L}(A_1) \otimes \cdots \otimes \overline{L}(A_l) \).  

Note that \( \dim \overline{V}(A) = 2^{k-h} \), where \( h \) is the number of \( c = 1, \ldots, l \) such that \( A_c \) has two equal entries.

**Lemma 8.3.** For any \( A \in \text{Tab}_\pi \), there is a nonzero homomorphism

\[
\overline{M}(A) \to \overline{V}(A)
\]

sending the cyclic vector \( 1 \otimes 1 \in \overline{M}(A) \) to \( v_+ \otimes \cdots \otimes v_+ \in \overline{V}(A) \). In particular, \( \overline{V}(A) \) contains a subquotient isomorphic to \( \overline{L}(A) \).

**Proof.** Suppose that \( A = a_{b_1 \ldots b_l} \). By the definition of \( \overline{M}(A) \) as an induced module, it suffices to show that \( v := v_+ \otimes \cdots \otimes v_+ \in \overline{V}(A) \) is annihilated by all \( e^{(r)} \) for \( r > s_{1,2} \) and that \( d_1^{(r)}v = e_r(a_1, \ldots, a_k)v \) and \( d_2^{(r)}v = e_r(b_1, \ldots, b_l)v \) for all \( r > 0 \). For this, we calculate from the explicit formulae for the invariants \( d_1^{(r)} \), \( d_2^{(r)} \) and \( e^{(r)} \) given by (4-10) and (4-19)–(4-21), remembering that their action on \( v \) is defined via the Miura transform \( \mu = \Delta_{1,\ldots,1} \). It is convenient in this proof to set

\[
e_i^{[c]} := \begin{cases} (-1)^{|i|}1 \otimes (c-1) \otimes e_i \otimes 1 \otimes (l-c) & \text{if } q_c = 2, \\ (-1)^21 \otimes (c-1) \otimes e_1 \otimes 1 \otimes (l-c) & \text{if } q_c = 1 \text{ and } i = j = 2, \\ 0 & \text{otherwise} \end{cases}
\]

for any \( 1 \leq i, j \leq 2 \) and \( 1 \leq c \leq l \), where \( q_c \) is the number of boxes in the \( c \)-th column of \( \pi \). First we have that

\[
d_1^{(r)}v = \sum_{1 \leq c_1, \ldots, c_r \leq l} \sum_{1 \leq h_1, \ldots, h_{r-1} \leq 2} \varepsilon^{[c_1]}_{1,h_1} \varepsilon^{[c_2]}_{1,h_2} \cdots \varepsilon^{[c_r]}_{h_{r-1},l} v
\]

summing only over terms with \( c_1 < \cdots < c_r \). The elements on the right commute (up to sign) because the \( c_i \) are all distinct, so any \( \varepsilon^{[c_i]}_{1,1} \) produces 0 as \( e_{1,2}v_+ = 0 \). Thus, the summation reduces just to

\[
\sum_{1 \leq c_1 < \cdots < c_r \leq l} \varepsilon^{[c_1]}_{1,1} \cdots \varepsilon^{[c_r]}_{1,1} v = e_r(a_1, \ldots, a_k)v
\]

as required. Next we have that

\[
d_2^{(r)}v = \sum_{1 \leq c_1, \ldots, c_r \leq l} \sum_{1 \leq h_1, \ldots, h_{r-1} \leq 2} (-1)^{|i|+1,\ldots,r-1|\text{row}(h_i)|=1} \varepsilon^{[c_1]}_{2,h_1} \varepsilon^{[c_2]}_{h_1,h_2} \cdots \varepsilon^{[c_r]}_{h_{r-1},l} v
\]
summing only over terms with $c_i \geq c_{i+1}$ if row$(h_i) = 1$ and $c_i < c_{i+1}$ if row$(h_i) = 2$. Here, if any monomial $\bar{e}_{1,2}^{[c_i]}$ appears, the rightmost such can be commuted to the end when it acts as 0. Thus, the summation reduces just to the terms with $h_1 = \cdots = h_{r-1} = 2$, and again we get the required elementary symmetric function $e_r(b_1, \ldots, b_l)$. Finally, we have that

$$e^{(r)}_v = \sum_{1 \leq c_1, \ldots, c_r \leq l} \sum_{1 \leq h_1, \ldots, h_{r-1} \leq 2} (-1)^{\#\{i=1, \ldots, r-1|\text{row}(h_i)=1\}} \bar{e}_{1,h_1}^{[c_1]} \bar{e}_{h_1,h_2}^{[c_2]} \cdots \bar{e}_{h_{r-1},2}^{[c_r]} v$$

summing only over terms with $c_i \geq c_{i+1}$ if row$(h_i) = 1$ and $c_i < c_{i+1}$ if row$(h_i) = 2$. As before, this is 0 because the rightmost $\bar{e}_{1,2}^{[c_i]}$ can be commuted to the end.

**Theorem 8.4.** Take any $A = \frac{a_1^{i_1} \cdots a_k^{i_k}}{b_1^{j_1} \cdots b_l^{j_l}} \in \text{Tab}_\pi$, and let $h \geq 0$ be maximal such that distinct $1 \leq i_1, \ldots, i_k \leq k$ and $1 \leq j_1, \ldots, j_l \leq l$ with $a_{i_1} = b_{j_1}, \ldots, a_{i_k} = b_{j_l}$ exist. Choose $B \sim A$ so that $B$ has $h$ columns of height 2 containing equal entries. Then

$$\bar{L}(A) \cong \bar{V}(B). \quad (8-4)$$

In particular, $\text{dim } \bar{L}(A) = 2^{k-h}$.

**Proof.** By Lemma 8.3, $\bar{V}(B)$ has a subquotient isomorphic to $\bar{L}(B) \cong \bar{L}(A)$, which implies that $\text{dim } \bar{L}(A) \leq \text{dim } \bar{V}(B) = 2^{k-h}$. Also by the linear independence established in the partial proof of Theorem 7.3 given in Section 7, we know that $\text{dim } \bar{L}(A) \geq 2^{k-h}$.

Theorem 8.4 also establishes the fact about dimension needed to complete the proof of Theorem 7.3 in Section 7.
