Pair correlation of angles between reciprocal geodesics on the modular surface

Florin P. Boca, Vicențiu Pașol, Alexandru A. Popa and Alexandru Zaharescu

The existence of the limiting pair correlation for angles between reciprocal geodesics on the modular surface is established. An explicit formula is provided, which captures geometric information about the length of reciprocal geodesics, as well as arithmetic information about the associated reciprocal classes of binary quadratic forms. One striking feature is the absence of a gap beyond zero in the limiting distribution, contrasting with the analog Euclidean situation.

1. Introduction

Let $\mathbb{H}$ denote the upper half-plane and $\Gamma = \text{PSL}_2(\mathbb{Z})$ the modular group. Consider the modular surface $X = \Gamma \backslash \mathbb{H}$, and let $\Pi : \mathbb{H} \to X$ be the natural projection. The angles on the upper half-plane $\mathbb{H}$ considered in this paper are the same as the angles on $X$ between the closed geodesics passing through $\Pi(i)$ and the image of the imaginary axis. These geodesics were first introduced in connection with the associated “self-inverse classes” of binary quadratic forms in the classical work of Fricke and Klein [1892, p. 164], and the primitive geodesics among them were studied recently and called reciprocal geodesics by Sarnak [2007]. The aim of this paper is to establish the existence of the pair correlation measure of their angles and to explicitly express it.

For $g \in \Gamma$, denote by $\theta_g \in [-\pi, \pi]$ the angle between the vertical geodesic $[i, 0]$ and the geodesic ray $[i, gi]$. For $z_1, z_2 \in \mathbb{H}$, let $d(z_1, z_2)$ denote the hyperbolic distance, and set

$$\|g\|^2 = 2 \cosh d(i, gi) = a^2 + b^2 + c^2 + d^2 \quad \text{for} \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{R}).$$

Keywords: modular surface, reciprocal geodesics, pair correlation, hyperbolic lattice points, hyperbolic lattice angles.
It was proved by Nicholls [1983] (see also [Nicholls 1989, Theorem 10.7.6]) that for any discrete subgroup $\Gamma$ of finite covolume in $\text{PSL}_2(\mathbb{R})$, the angles $\theta_\gamma$ are uniformly distributed, in the sense that for any fixed interval $I \subseteq [-\pi, \pi]$,\[
\lim_{R \to \infty} \frac{\#\{\gamma \in \Gamma : \theta_\gamma \in I, d(i, \gamma i) \leq R\}}{\#\{\gamma \in \Gamma : d(i, \gamma i) \leq R\}} = |I| \frac{2}{2\pi}.
\]

Effective estimates for the rate of convergence that allow one to take $|I| \asymp e^{-cR}$ as $R \to \infty$ for some constant $c = c_\Gamma > 0$ were proved for $\Gamma = \Gamma(N)$ by one of us [Boca 2007], and in general situations by Risager and Truelsen [2010] and by Gorodnik and Nevo [2012]. Other related results concerning the uniform distribution of real parts of orbits in hyperbolic spaces were proved by Good [1983], and more recently by Risager and Rudnick [2009].

The statistics of spacings, such as the pair correlation or the nearest neighbor distribution (also known as the gap distribution) measure the fine structure of sequences of real numbers in a more subtle way than the classical Weyl uniform distribution. Very little is known about the spacing statistics of closed geodesics. In fact, the only result that we are aware of, due to Pollicott and Sharp [2006], concerns the correlation of differences of lengths of pairs of closed geodesics on a compact surface of negative curvature, ordered with respect to the word length on the fundamental group.

This paper investigates the pair correlation of angles $\theta_\gamma$ with $d(i, \gamma i) \leq R$, or equivalently with $\|\gamma\|^2 \leq Q^2 = e^R \sim 2 \cosh R$ as $Q \to \infty$. As explained in Section 2, these are exactly the angles between reciprocal geodesics on the modular surface.

The Euclidean analog of this problem considers the angles between the line segments connecting the origin $(0, 0)$ with all integer points $(m, n)$ satisfying $m^2 + n^2 \leq Q^2$ as $Q \to \infty$. When only primitive lattice points are being considered (rays are counted with multiplicity one), the problem reduces to the study of the pair correlation of the sequence of Farey fractions with the $L^2$ norm $\|m/n\|^2_2 = m^2 + n^2$. Its pair correlation function is plotted on the left of Figure 1. When Farey fractions are ordered by their denominator, the pair correlation is shown to exist and it is explicitly computed in [Boca and Zaharescu 2005]. A common important feature is the existence of a gap beyond zero for the pair correlation function. This is an ultimate reflection of the fact that the area of a nondegenerate triangle with integer vertices is at least $\frac{1}{2}$, which corresponds to the familiar inequality $|b/d - a/c| \geq 1/cd$ satisfied by two lattice points $P = (a, b)$ and $Q = (c, d)$ with $\text{Area}(\triangle O P Q) > 0$.

For the hyperbolic lattice centered at $i$, it is convenient to start with the (nonuniformly distributed) numbers $\tan(\theta_\gamma/2)$ with multiplicities, rather than the angles $\theta_\gamma$ themselves. Employing obvious symmetries explained in Section 3, it is further convenient to restrict to a set of representatives $\Gamma_1$ consisting of matrices $\gamma$ with nonnegative entries such that the point $\gamma i$ is in the first quadrant in Figure 2. The
pair correlation measures of the finite set $\mathcal{A}_Q$ of elements $\theta_\gamma$ with $\gamma \in \Gamma_1$ and $\|\gamma\| \leq Q$ (counted with multiplicities) is defined as

$$R^3_Q(\xi) = \frac{1}{B_Q} \# \{ (\gamma, \gamma') \in \Gamma^2_1 : \|\gamma\|, \|\gamma'\| \leq Q, \gamma' \neq \gamma, 0 \leq \frac{2}{\pi} (\theta_{\gamma'} - \theta_\gamma) \leq \frac{\xi}{B_Q} \},$$

where $B_Q \sim \frac{3}{8} Q^2$ denotes the number of elements $\gamma \in \Gamma_1$ with $\|\gamma\| \leq Q$. As it will be used in the proof, we similarly define the pair correlation measure $R^5_Q(\xi)$ of the set $\Sigma_Q$ of elements $\tan(\theta_\gamma/2)$ with $\gamma \in \Gamma_1$ and $\|\gamma\| \leq Q$.

One striking feature, illustrated by the numerical calculations in Figure 1, points to the absence of a gap beyond zero in the limiting distribution, in contrast with the analog Euclidean situation.

The main result of this paper is the proof of existence and explicit computation of the pair correlation measure $R^3_A$ given by

$$R^3_A(\xi) = R^3(0, \xi] := \lim_{Q \to \infty} R^3_Q(\xi),$$

and similarly for $R^5_A$, thus answering a question raised in [Boca 2007].

To give a precise statement, consider $\mathcal{G}$, the free semigroup on two generators $L = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ and $R = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. Repeated application of the Euclidean algorithm shows that $\mathcal{G} \cup \{ I \}$ coincides with the set of matrices in $SL_2(\mathbb{Z})$ with nonnegative entries. The explicit formula for $R^3_2(\xi)$ is given as a series of volumes summed over $\mathcal{G}$, plus a finite sum of volumes, and it is stated in Theorem 2 (Section 7). The formula for $R^5_2(\xi)$ leads to an explicit formula for $R^3_A(\xi)$, which we state here, partly because the pair correlation function for the angles $\theta_\gamma$ is more interesting, being equidistributed, and partly because the formula we obtain is simpler.

**Theorem 1.** The pair correlation measure $R^3_A$ on $[0, \infty)$ exists and is given by

$$R^3_A(\frac{3}{4\pi} \xi) = \frac{8}{3\xi(2)} \left( \sum_{M \in \mathcal{G}} B_M(\xi) + \sum_{\ell \in [0, \xi/2)} \sum_{K \in [1, \xi/2)} A_{K, \ell}(\xi) \right),$$

(1-2)

For $M \in \mathcal{G}$, letting $U_M = \|M\|^2/\sqrt{\|M\|^4 - 4}$, $\theta_M$ as above, and $f_+ = \max\{f, 0\}$, we have

$$B_M(\xi) = \frac{\pi}{4} \int_0^{\pi/2} \frac{\left( 1/\sqrt{\|M\|^4 - 4} - \sin(2\theta - \theta_M)/\xi \right)_+}{U_M + \cos(2\theta - \theta_M)} d\theta.$$

For integers $\ell \in [0, \xi/2)$, $K \in [1, \xi/2)$, we have

$$A_{K, \ell}(\xi) = \int_0^{\pi/4} A_{K, \ell}(\frac{\xi}{2\cos^2 t}, t) \frac{dt}{\cos^2 t},$$

where $A_{K, \ell}(\frac{\xi}{2\cos^2 t}, t) = \int_0^{\pi/4} A_{K, \ell}(\frac{\xi}{2\cos^2 t}, t) \frac{dt}{\cos^2 t},$
where $A_{K,\ell}(\xi, t)$ is the area of the region defined by those $re^{i\theta} \in [0, 1]^2$ such that
\[
L_{\ell+1}(e^{i\theta}) > 0, \quad \frac{F_{K,\ell}(\theta)}{\xi} \leq r^2 \leq \frac{\cos^2 t}{\max\{1, L_{\ell}^2(e^{i\theta}) + L_{\ell+1}^2(e^{i\theta})\}},
\]
with $e^{i\theta} = (\cos \theta, \sin \theta)$, the piecewise linear functions $L_i$ as defined in (5-5), and
\[
F_{K,\ell}(\theta) := \cot \theta + \sum_{i=1}^{\ell} \frac{1}{L_{i-1}(e^{i\theta})L_i(e^{i\theta})} + \frac{L_{\ell+1}(e^{i\theta})}{L_{\ell}(e^{i\theta})(L_{\ell}^2(e^{i\theta}) + L_{\ell+1}^2(e^{i\theta}))}.
\]
Rates of convergence in (1-1) are effectively described in the proof of Theorem 2 and in Proposition 15.

When $\xi \leq 2$, the second sum in (1-2) disappears and the derivative $B'_M(\xi)$ is explicitly computed in Lemma 17, yielding an explicit formula for the pair correlation density function $g_{A_2}(\xi) = dR_{A_2}(\xi)/d\xi$, which matches the graph in Figure 1.

**Corollary 1.** For $0 < \xi \leq 2$ we have
\[
g_{A_2}^q\left(\frac{3}{4\pi}\xi\right) = \frac{16}{3\xi^2} \sum_{M \in \mathcal{G}} \ln\left(\frac{\|M\|^2 + \sqrt{\|M\|^4 - 4}}{\|M\|^2 + \sqrt{\|M\|^4 - 4} - \xi^2}\right).
\]
A formula valid for $0 < \xi \leq 4$ is given in (8-11) after computing $A'_{0,K}(\xi)$.

![Figure 1.](image-url) The pair correlation functions $g_{A_2}^q$ (left) and $g_{A_2}^q$ (right), plotted in gray, compared with the pair correlation function of Farey fractions with $L^2$ norm (left), and of the angles (with multiplicities) of lattice points in Euclidean balls (right). The graphs are obtained by counting the pairs in their definition, using $Q = 4000$, for which $B_Q = 6000203$. We used Magma [Bosma et al. 1997] for the numerical computations, and SAGE [Stein et al. 2012] for plotting the graphs.
The computation is performed in Section 8.2, and it identifies the first spike in the graph of $g_2^\mathfrak{ai}(x)$ at $x = (3/4\pi)\sqrt{5}$. A proof of an explicit formula for the pair correlation density $g_2^\mathfrak{ai}(x)$ valid for all $x$, and working also when the point $i$ is replaced by the other elliptic point $\rho = e^{\pi i/3}$, will be given in [Boca et al. 2013].

Since the series in Corollary 1 is dominated by the absolutely convergent sum $\sum M \xi^2 \|M\|^{-4}$, we can take the limit as $\xi \to 0$:

$$g_2^\mathfrak{ai}(0) = \frac{2}{3} \sum_{M \in \mathfrak{S}} \left( \frac{\|M\|^2}{\sqrt{\|M\|^4 - 4}} - 1 \right) = 0.7015 \ldots$$

Remarkably, the previous two formulas, as well as (1-2) for $\xi \leq 2$, can be written geometrically as a sum over the primitive closed geodesics $\mathfrak{c}$ on $X$ which pass through the point $\Pi(i)$, where the summand depends only on the length $\ell(\mathfrak{c})$:

$$g_2^\mathfrak{ai}(0) = \frac{8}{3} \sum_{\mathfrak{c}} \sum_{n \geq 1} \frac{1}{e^{n\ell(\mathfrak{c})} - 1}.$$

This is proved in Section 2, where we also give an arithmetic version based on an explicit description of the reciprocal geodesics $\mathfrak{c}$ due to Sarnak [2007].

For the rest of the introduction we sketch the main ideas behind the proof, describing also the organization of the article. After reducing to angles in the first quadrant in Section 3, we show that the pair correlation of the quantities $9(\gamma) = \tan(\theta_\gamma/2)$ is identical to that of $8(\gamma) = \text{Re}(\gamma i)$. We are led to estimating the cardinality of the set

$$\{(\gamma, \gamma') \in \Gamma_1^2 : \|\gamma\|, \|\gamma'\| \leq Q, \gamma' \neq \gamma, 0 \leq Q^2(\Phi(\gamma') - \Phi(\gamma)) \leq \xi\}.$$

For a matrix $\gamma = \begin{pmatrix} p' & p \\ q' & q \end{pmatrix}$ with nonnegative entries, $\|\gamma\| \leq Q$, and $q, q' > 0$, consider the associated Farey interval $[p/q, p'/q']$, which contains $\Phi(\gamma)$. In Section 4, we break the set of pairs $(\gamma, \gamma')$ above in two parts, depending on whether one of the associated Farey intervals contains the other, or the two intervals intersect at most at one endpoint. In the first case we have $\gamma = \gamma' M$ or $\gamma' = \gamma M$ with $M \in \mathfrak{S}$, while in the second we have a similar relation depending on the number $\ell$ of consecutive Farey fractions there are between the two intervals. The first case contributes to the series over $\mathfrak{S}$ in (1-2), while the second case contributes to the sum over $K, \ell$. The triangle map $T$ whose iterates define the piecewise linear functions $L_i(x, y)$, first introduced in [Boca et al. 2001], makes its appearance in the second case, being related to the denominator of the successor function for Farey fractions.

To estimate the number of pairs $(\gamma, \gamma M)$ in the first case, a key observation is that for each $M \in \Gamma$ there exists an explicit elementary function $\Xi_M(x, y)$, given by (5-1), such that

$$\Phi(\gamma) - \Phi(\gamma M) = \Xi_M(q', q).$$
for γ as above. Together with estimates for the number of points in two dimensional regions based on bounds on Kloosterman sums (Lemma 7), this allows us to estimate the number of pairs (γ, γM) with fixed M ∈ S, in terms of the volume of a three dimensional body SM,ξ given in (7-14). The absence of a gap beyond zero in the pair correlation measure arises as a result of this estimate. The details of the calculation are given in Section 7, leading to an explicit formula for R2 (Theorem 2).

Finally in Section 8 we pass to the pair correlation of the angles θγ, obtaining the formulas of Theorem 1 and Corollary 1.

In this paper we focus on the full modular lattice centered at i, both because of the arithmetic connection with reciprocal geodesics, and because in this case the connection between unimodular matrices and Farey intervals is most transparent. It is this connection and the intuition provided by the repulsion of Farey fractions that guides our argument, and leads to the explicit formula for the pair correlation function, which is the first of this kind for hyperbolic lattices.

In a subsequent paper [Boca et al. 2013], we abstract some of this intuition and propose a different conjectural formula for the pair correlation function of an arbitrary lattice in PSL2(ℝ), centered at a point on the upper half plane, which we prove for the full level lattice centered at elliptic points. While the formula in that paper is more general, the method of proof, and the combinatorial-geometric intuition behind it, is reflected more accurately in the formula of Theorem 1: the infinite sum in the formula corresponds to pairs of matrices where there is no repulsion between their Farey intervals, while the finite sum corresponds to pairs of matrices where there is repulsion. The approach used in [Boca et al. 2013] builds on the estimates and method of the present paper.

A proof of that paper’s conjecture by spectral methods has been proposed in a preprint by Kelmer and Kontorovich [2013]. By comparison, our approach is entirely elementary (using only standard bounds on Kloosterman sums), and via the repulsion argument it provides a natural way of approximating the pair correlation function. A key insight in the present paper, which is also the starting point of [Boca et al. 2013] and [Kelmer and Kontorovich 2013], is that instead of counting pairs (γ, γ′) ∈ Γ × Γ in the definition of the pair correlation measure, we fix a matrix M, count pairs (γ, γM), and sum over M. The same approach may prove useful for the pair correlation problem for lattices in other groups as well.

## 2. Reciprocal geodesics on the modular surface

In this section we recall the definition of reciprocal geodesics and explain how the pair correlation of the angles they make with the imaginary axis is related to the pair correlation considered in the introduction. We also show that the sums over the semigroup S appearing in the introduction can be expressed geometrically in
Angles between reciprocal geodesics. A description of the trajectory of reciprocal geodesics on the fundamental domain seems to have first appeared in the classical work of Fricke and Klein [1892, p.164], where it is shown that they consist of two closed loops, one the reverse of the other. There the terminology “sich selbst inverse Classe” is used for the equivalence classes of quadratic forms corresponding to reciprocal conjugacy classes of hyperbolic matrices.

Oriented closed geodesics on $X$ are in one-to-one correspondence with conjugacy classes $\{\gamma\}$ of hyperbolic elements $\gamma \in \Gamma$. To a hyperbolic element $\gamma \in \Gamma$ one attaches its axis $a_\gamma$ on $\mathbb{H}$, namely the semicircle whose endpoints are the fixed points of $\gamma$ on the real axis. The part of the semicircle between $z_0$ and $\gamma z_0$, for any $z_0 \in a_\gamma$, projects to a closed geodesic on $X$, with multiplicity one if and only if $\gamma$ is a primitive matrix (not a power of another hyperbolic element of $\Gamma$). The group that fixes the semicircle $a_\gamma$ (or equivalently its endpoints on the real axis) is generated by one primitive element $\gamma_0$.

We are concerned with (oriented) closed geodesics passing through $\Pi(i)$ on $X$. Since the axis of a hyperbolic element $A$ passes through $i$ if and only if $A$ is symmetric, the closed geodesics passing through $\Pi(i)$ correspond to the set $R$ of hyperbolic conjugacy classes $\{\gamma\}$ which contain a symmetric matrix. The latter are exactly the reciprocal geodesics considered in [Sarnak 2007], where only primitive geodesics are considered.

The reciprocal geodesics can be parametrized in a two-to-one manner by the set $\mathcal{G} \subset \Gamma$, defined in the introduction, which consists of matrices distinct from the identity with nonnegative entries. To describe this correspondence, let $\mathcal{A} \subset \Gamma$ be the set of symmetric hyperbolic matrices with positive entries. Then we have maps

$$\mathcal{G} \to \mathcal{A} \to R$$

(2.1)

where the first map takes $\gamma \in \mathcal{G}$ to $A = \gamma \gamma^t$, and the second takes the hyperbolic symmetric $A$ to its conjugacy class $\{A\}$. The first map is bijective, while the second is two-to-one and onto, as follows from [Sarnak 2007]. More precisely, if $A = \gamma \gamma^t \in \mathcal{A}$ is a primitive matrix, then $B = \gamma' \gamma \neq A$ is the only other matrix in $\mathcal{A}$ conjugate to $A$, and $\{A^n\} = \{B^n\}$ for all $n \geq 0$.

Note also that $\|\gamma\|^2 = \text{Tr}(\gamma \gamma^t)$, and if $A$ is hyperbolic with $\text{Tr}(A) = T$, then the length of the geodesic associated to $\{A\}$ is $2 \ln N(A)$ with $N(A) = \frac{1}{2} (T + \sqrt{T^2 - 4})$.

**Lemma 2.** Let $A \in \Gamma$ be a hyperbolic symmetric matrix and let $\gamma \in \Gamma$ such that $A = \gamma \gamma^t$. Then the point $\gamma i$ is halfway (in hyperbolic distance) between $i$ and $Ai$ on the axis of $A$.

**Proof.** We have $d(i, \gamma i) = d(i, \gamma' i) = d(\gamma i, Ai)$ where the first equality follows from the hyperbolic distance formula and the second since $\Gamma$ acts by isometries
on \( \mathbb{H} \). Using formula (3-3), one checks that the angles of \( i, \gamma i \) and \( i, A_i \) are equal, hence \( \gamma i \) is indeed on the axis of \( A \).

We can now explain the connection between the angles \( \theta_\gamma \) in the first and second quadrant in Figure 2, and the angles made by the reciprocal geodesics with the image \( \Pi(i \to i\infty) = \Pi(i \to 0) \). Namely, points in the first and second quadrant are parametrized by \( \gamma i \) with \( \gamma \in \mathcal{S} \), and by the lemma the reciprocal geodesic corresponding to \( A = \gamma \gamma^t \in \mathcal{A} \) consists of the loop \( \Pi(i \to \gamma i) \), followed by \( \Pi(i \to \gamma^t i) \) (which is the same as the reverse of the first loop). Therefore to each reciprocal geodesic corresponding to \( A = \gamma \gamma^t \in \mathcal{A} \) correspond two angles, those attached to \( \gamma i \) and \( \gamma^t i \) in Figure 2, measured in the first or second quadrant so that all angles are between 0 and \( \pi/2 \).

In conclusion, the angles made by the reciprocal geodesics on \( X \) with the fixed direction \( \Pi(i \to i\infty) \) consist of the angles in the first quadrant considered before, each appearing twice. Ordering the points \( \gamma i \) in the first quadrant by \( \| \gamma \| \) corresponds to ordering the geodesics by their length. Therefore the pair correlation measure of the angles of reciprocal geodesics is \( 2R_A^2(\xi/2) \), where \( R_A^2 \) was defined in the introduction.

The parametrization (2-1) of reciprocal geodesics allows one to rewrite the series appearing in the formula for \( g_A^2(0) \) in the introduction, as a series over the primitive reciprocal classes \( \mathcal{R}_{\text{prim}} \):

\[
\sum_{M \in \mathcal{S}} \left( \frac{\|M\|^2}{\sqrt{\|M\|^4 - 4}} - 1 \right) = \sum_{A \in \mathcal{A}} \frac{2}{N(A)^2 - 1} = 4 \sum_{\{\gamma\} \in \mathcal{R}_{\text{prim}}} \sum_{n \geq 1} \frac{1}{N(\gamma)^{2n} - 1},
\]

where we have used the fact that for a hyperbolic matrix \( A \) of trace \( T \) we have

\[
\sqrt{T^2 - 4} = N(A) - N(A)^{-1} \quad \text{and} \quad N(A^n) = N(A)^n.
\]

One can rewrite the sum further using the arithmetic description of primitive reciprocal geodesics given in [Sarnak 2007]. Namely, let \( \mathcal{D}_{\mathbb{R}} \) be the set of nonsquare positive discriminants \( 2^\alpha D' \) with \( \alpha \in \{0, 2, 3\} \) and \( D' \) odd divisible only by primes \( p \equiv 1 \pmod{4} \). Then the set of primitive reciprocal classes \( \mathcal{R}_{\text{prim}} \) decomposes as a disjoint union of finite sets:

\[
\mathcal{R}_{\text{prim}} = \bigcup_{d \in \mathcal{D}_{\mathbb{R}}} \mathcal{R}_{d}^{\text{prim}},
\]

with \( |\mathcal{R}_{d}^{\text{prim}}| = v(d) \), the number of genera of binary quadratic forms of discriminant \( d \). If \( d \in \mathcal{D}_{\mathbb{R}} \) has exactly \( \lambda \) odd prime factors, \( v(d) \) equals \( 2^\lambda \) if 8 divides \( d \) and \( 2^{\lambda-1} \) otherwise. Each class \( \{\gamma\} \in \mathcal{R}_{d}^{\text{prim}} \) has

\[
N(\gamma) = \alpha_d = \frac{1}{2}(u_0 + v_0 \sqrt{d}),
\]
with \((u_0, v_0)\) the minimal positive solution to Pell’s equation \(u^2 - dv^2 = 4\). We then have
\[
\sum_{\gamma \in \mathcal{P}_{\text{prim}}} \sum_{n \geq 1} \frac{1}{N(\gamma)^{2n} - 1} = \sum_{d \in \mathcal{D}} \sum_{n \geq 1} \frac{v(d)}{\alpha_d^{2n} - 1}.
\]

In the same way, by Lemma 13 the pair correlation measure \(R_T^\xi(\xi)\) in Theorem 1 can be written for \(\xi \leq 1\) as a sum over classes \(\{\gamma\} \in \mathcal{P}_{\text{prim}}\), where each summand depends only on \(\xi\) and \(N(\gamma)\).

### 3. Reduction to the first quadrant

In this section we establish notation in use throughout the paper, and we reduce the pair correlation problem to angles in the first quadrant. A similar reduction can be found in [Chamizo 2006], in the context of visibility problems for the hyperbolic lattice centered at \(i\).

For each matrix \(g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \SL_2(\mathbb{R})\), define the quantities
\[
X_g = a^2 + b^2, \quad Y_g = c^2 + d^2, \quad Z_g = ac + bd, \quad T_g = X_g + Y_g = \|g\|^2, \quad \Phi(g) = \Re(gi) = \frac{Z_g}{Y_g}, \quad \epsilon_g = \epsilon_T = \frac{1}{2}(T_g - \sqrt{T_g^2 - 4}).
\]

The upper half-plane \(\mathbb{H}\) is partitioned into four quadrants:
\[
\mathcal{I} = \{z \in \mathbb{H} : \Re z > 0, |z| < 1\}, \quad \mathcal{II} = \{z \in \mathbb{H} : \Re z > 0, |z| > 1\}, \quad \mathcal{III} = \{z \in \mathbb{H} : \Re z < 0, |z| > 1\}, \quad \mathcal{IV} = \{z \in \mathbb{H} : \Re z < 0, |z| < 1\}.
\]

Note that all the points \(gi\) for \(g \in \Gamma\) lie in one of the four open quadrants, with the exception of \(i\) itself. This follows from the relation
\[
X_gY_g - Z_g^2 = 1,
\]
which will be often used.

In this section, simply take \(X = X_g, Y = Y_g, Z = Z_g, \theta = \theta_g\). A direct calculation shows that the center of the circle through \(i\) and \(gi\) is \(\alpha = (X - Y)/(2Z)\), leading to
\[
\tan \theta_g = -\frac{1}{\alpha} = \frac{2Z_g}{Y_g - X_g} \quad \text{for all } \theta_g \in [-\pi, \pi].
\]

Plugging this into
\[
\tan \frac{\theta}{2} = \frac{\tan \theta}{1 + \sqrt{1 + \tan^2 \theta}} \quad \text{if } |\theta| < \frac{\pi}{2} \quad \text{or} \quad \tan \frac{\theta}{2} = -\frac{1 + \sqrt{1 + \tan^2 \theta}}{\tan \theta} \quad \text{if } \frac{\pi}{2} < |\theta| < \pi,
\]
and employing (3-2) and the equivalences \(|gi| < 1 \iff X < Y\) and \(\text{Re}(\gamma i) > 0 \iff Z > 0\), we find the useful formulas
\[
\Psi(g) := \tan \frac{\theta_g}{2} = \frac{\sqrt{T_g^2 - 4 + X_g - Y_g}}{2Z_g} = \frac{X_g - \epsilon_g}{Z_g} = \frac{Z_g}{Y_g - \epsilon_g}
\]  
(3-3)
for all \( \theta_g \in [-\pi, \pi] \).

We set \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \), \( \tilde{\gamma} = \begin{pmatrix} d & b \\ c & a \end{pmatrix} \), \( s = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \). Let \( \gamma \in \Gamma, \gamma \neq I, s \). For \( \gamma i \) to be in the right half-plane we need \( \text{Re}(\gamma i) > 0 \). This is equivalent to \( ac + bd > 0 \), and implies that \( ac \geq 0 \) and \( bd \geq 0 \) because \( abcd = bc + (bc)^2 \geq 0 \). Since \( ac \geq 0 \), without loss of generality we will assume that \( a \geq 0 \) and \( c \geq 0 \) (otherwise consider \(-\gamma \) instead). Without loss of generality, we will assume that \( b \geq 0 \), \( d \geq 0 \) as well (otherwise, we consider \(-\gamma s = \begin{pmatrix} -b & a \\ -d & c \end{pmatrix} \) instead, since \( \gamma i = \gamma si \)). Thus \( \gamma \) has only nonnegative entries.

If \( a, b, c, d \geq 0 \) and \( ad - bc = 1 \), then \( c/a \) and \( d/b \) are both \( \leq 1 \) or both \( \geq 1 \) (since open intervals between consecutive Farey fractions are either nonintersecting or one contains the other). Since \( \gamma i \in I \iff a^2 + b^2 < c^2 + d^2 \), it follows that both \( a/c \) and \( b/d \) are \( \leq 1 \) for \( \gamma i \in I \). We conclude that among the eight matrices \( \pm \gamma, \pm \gamma s, \pm \tilde{\gamma}, \pm \tilde{\gamma} s \), which have symmetric angles (see Figure 2), the one for which \( \gamma i \) is in quadrant \( I \) can be chosen such that

\[
a, b, c, d \geq 0 \quad \text{and} \quad 0 \leq \frac{b}{d} < \frac{a}{c} \leq 1.
\]

The set of such matrices \( \gamma \) is denoted \( \Gamma_I \).

Consider the subset \( \mathcal{R}_Q \) of \( \Gamma_I \) consisting of matrices with entries at most \( Q \):

\[
\mathcal{R}_Q := \left\{ \begin{pmatrix} p' & p \\ q' & q \end{pmatrix} \in \Gamma : 0 \leq p, p', q, q' \leq Q, \frac{p}{q} < \frac{p'}{q'} \leq 1 \right\},
\]
and its subset \( \tilde{\mathcal{R}}_Q \) consisting of those \( \gamma \) with \( \|\gamma\| \leq Q \). The cardinality \( B_Q \) of \( \tilde{\mathcal{R}}_Q \) is estimated in Corollary 8 as \( B_Q \sim 3Q^2/8 \), in agreement with formula (58) in [Sarnak 2007] for the number of reciprocal geodesics of length at most \( x = Q^2 \).

Let \( \mathcal{F}_Q \) be the set of Farey fractions \( p/q \) with \( 0 \leq p \leq q \leq Q \) and \( (p, q) = 1 \). The Farey tessellation (Figure 3) consists of semicircles on the upper half-plane.

\begin{figure}
\centering
\includegraphics{figure2}
\caption{Two symmetric geodesics through \( i \).}
\end{figure}
connecting Farey fractions $0 \leq p/q < p'/q' \leq 1$ with $p'q - pq' = 1$. We associate to matrices $\gamma \in \mathcal{R}_Q$, with entries as above the arc in the Farey tessellation connecting $p/q$ and $p'/q'$, and conclude that

$$\# \mathcal{R}_Q = 2\# \mathcal{F}_Q - 3 = \frac{Q^2}{\zeta(2)} + O(Q \ln Q).$$

4. The coincidence of the pair correlations of $\Phi$ and $\Psi$

In this section we show that the limiting pair correlations of the sets $\{\Psi(\gamma)\}$ and $\{\Phi(\gamma)\}$ ordered by $\|\gamma\| \to \infty$ do coincide. The proof uses properties of the Farey tessellation, via the correspondence between elements of $\mathcal{R}_Q$ and arcs in the Farey tessellation defined at the end of Section 3.

For $\gamma = \left(\frac{p'}{q'}, \frac{p}{q}\right)$, set $\gamma_- = p/q$, $\gamma_+ = p'/q'$. From (3-1), (3-3), and the inequalities $X_\gamma < Z_\gamma < Y_\gamma$, $2Y_\gamma > T_\gamma$ and $\epsilon_\gamma < 1/T_\gamma$, we have:

$$\Psi(\gamma) - \Phi(\gamma) = \frac{Z_\gamma}{Y_\gamma(\epsilon_\gamma^{-1}Y_\gamma - 1)} \ll \frac{1}{\|\gamma\|^4},$$

$$(4-1)$$

$$\gamma_- < \Phi(\gamma) < \Psi(\gamma) < \gamma_+. \quad (4-2)$$

Denote by $\mathcal{R}_Q^\Psi(\xi)$ (resp. $\mathcal{R}_Q^\Phi(\xi)$) the number of pairs $(\gamma, \gamma') \in \tilde{\mathcal{R}}_Q^2$, $\gamma \neq \gamma'$, such that $0 \leq \Psi(\gamma) - \Psi(\gamma') \leq \xi/Q^2$ (resp. $0 \leq \Phi(\gamma) - \Phi(\gamma') \leq \xi/Q^2$). For fixed $\beta \in \left(\frac{2}{3}, 1\right)$, consider also

$$\mathcal{N}_{Q, \xi, \beta}^\Psi := \#\{(\gamma, \gamma') \in \tilde{\mathcal{R}}_Q^2 : Q^2|\Psi(\gamma) - \Psi(\gamma')| \leq \xi, \|\gamma\| \leq Q^\beta\},$$

and the similarly defined $\mathcal{N}_{Q, \xi, \beta}^\Phi$. The trivial inequality

$$\mathcal{R}_Q^\Phi(\xi) \leq 2\mathcal{N}_{Q, \xi, \beta}^\Phi$$

$$+ \#\{(\gamma, \gamma') \in \tilde{\mathcal{R}}_Q^2 : \gamma \neq \gamma', Q^2|\Phi(\gamma) - \Phi(\gamma')| \leq \xi, \|\gamma\|, \|\gamma'\| \geq Q^\beta\}$$
and the estimate in (4-1) show that there exists a universal constant \( \kappa > 0 \) such that

\[
\mathcal{R}_Q^\psi(\xi) \leq 2N_{Q,\xi,\beta}^\Phi + \# \{ (\gamma, \gamma') \in \hat{\mathcal{R}}_Q^2 : \gamma \neq \gamma', \ -2\kappa Q^{-\beta} \leq \Psi(\gamma) - \Psi(\gamma') \leq \xi Q^{-2} + 2\kappa Q^{-\beta} \},
\]

showing that

\[
\mathcal{R}_Q^\psi(\xi) \leq 2N_{Q,\xi,\beta}^\Phi + \mathcal{R}_Q^\psi(2\kappa Q^{-\beta}) + \mathcal{R}_Q^\psi(\xi + 2\kappa Q^{-\beta}).
\]  

(4-3)

In a similar way we show that

\[
\mathcal{R}_Q^\psi(\xi) \leq 2N_{Q,\xi,\beta}^\Phi + \mathcal{R}_Q^\psi(2\kappa Q^{-\beta}) + \mathcal{R}_Q^\psi(\xi + 2\kappa Q^{-\beta}).
\]  

(4-4)

We first prove that \( N_{Q,\xi,\beta}^\Phi \) and \( N_{Q,\xi,\beta}^\Psi \) are much smaller than \( Q^2 \). For this goal and for later use, it is important to divide pairs \( (\gamma, \gamma') \in \hat{\mathcal{R}}_Q \) in three cases, depending on the relative position of their associated arcs in the Farey tessellation (it is well known that two arcs in the Farey tessellation are nonintersecting):

(i) The arcs corresponding to \( \gamma \) and \( \gamma' \) are exterior, i.e., \( \gamma_+ \leq \gamma'_- \) or \( \gamma'_+ \leq \gamma_- \).

(ii) \( \gamma' \preceq \gamma \), i.e., \( \gamma_- \leq \gamma'_- < \gamma'_+ \leq \gamma_+ \).

(iii) \( \gamma \preceq \gamma' \), i.e., \( \gamma'_- \leq \gamma_- < \gamma_+ \leq \gamma'_+ \).

**Proposition 3.** \( N_{Q,\xi,\beta}^\Phi \ll Q^{1+\beta} \ln Q \) and \( N_{Q,\xi,\beta}^\Psi \ll Q^{1+\beta} \ln Q \).

**Proof.** \( N_{Q,\xi,\beta}^\Phi \) and \( N_{Q,\xi,\beta}^\Psi \) are increasing as an effect of enlarging \( \tilde{\mathcal{R}}_Q \) to \( \mathcal{R}_Q \), so for this proof we will replace \( \tilde{\mathcal{R}}_Q \) by \( \mathcal{R}_Q \). We only consider \( N_{Q,\xi,\beta}^\Phi \) here. The proof for the bound on \( N_{Q,\xi,\beta}^\Psi \) is identical. Both rely on (4-1) and (4-2).

Set \( K = [\xi] + 1 \). From (4-2) and the fact that \( |r' - r| \geq 1/Q^2 \) for all \( r, r' \in \mathcal{F}_Q \) such that \( r \neq r' \), it follows that

\[
\#(\mathcal{F}_Q \cap [\gamma_+, \gamma'_-]) \leq K + 1
\]

if \( \gamma_+ \leq \gamma'_- \) and \( |\Phi(\gamma') - \Phi(\gamma)| \leq \xi/Q^2 \). In particular, \( \gamma'_- = \gamma_+ \) when \( 0 < \xi < 1 \).

We now consider the three cases listed before the statement of the proposition:

(i) The arcs corresponding to \( \gamma \) and \( \gamma' \) are exterior. Without loss of generality, assume that \( \gamma_+ \leq \gamma'_- \). If \( i \) is such that \( \gamma_+ = \gamma_i \), the \( i \)-th element of \( \mathcal{F}_Q \), then

\[
\gamma'_- = \gamma_{i+r} = \frac{p_{i+r}}{q_{i+r}}
\]

for some \( r \) with \( 0 \leq r < K \). The equality \( p'_+ q'_- - p'_- q'_+ = 1 \) shows that if \( \gamma'_- = p'_- / q'_- \) is fixed, then \( q'_+ \) (and therefore \( \gamma'_+ = p'_+ / q'_+ \)) is uniquely determined in intervals of length at most \( q'_- \). Since \( q'_- \leq Q \), it follows that the number of choices for \( q'_+ \) is actually at most \( (Q/q'_-) + 1 = (Q/q_{i+r}) + 1 \).
When $0 < \xi < 1$ one must have $\gamma' = \gamma_+$. Knowing $q_-$ and $q_+$ would uniquely determine the matrix $\gamma$. Then there will be at most $(Q/q_+) + 1$ choices for $\gamma'$, so the total contribution of this case to $N_{Q,\xi,\beta}$ is at most

$$\sum_{1 \leq q_- \leq Q^\beta} \sum_{1 \leq q_+ \leq Q^\beta} \left( \frac{Q}{q_+} + 1 \right) \ll Q^{1+\beta} \ln Q.$$ 

When $\xi \geq 1$ denote by $q_i, q_{i+1}, \ldots, q_{i+K}$ the denominators of $\gamma_i, \gamma_{i+1}, \ldots, \gamma_{i+K}$. Since $q_i < Q^\beta$, we have

$$\gamma_{i+K} - \gamma_i \leq \frac{K}{Q} \leq \frac{1}{Q^\beta} \leq \frac{1}{q_i} \leq 1 - \gamma_i,$$

showing that $i + K < \#\mathcal{F}_Q$ so long as $Q \gg \xi$. As noticed in [Hall and Tenenbaum 1984],

$$q_{j+2} = \left[ \frac{Q + q_j}{q_{j+1}} \right] q_{j+1} - q_j.$$

As in [Boca et al. 2001], consider

$$\kappa(x, y) := \left[ \frac{1+x}{y} \right] \quad \text{and} \quad \mathcal{T}_k = \{(x, y) \in (0, 1]^2 : x + y > 1, \kappa(x, y) = k\}.$$

Let $Q$ be large enough so that $\delta_0 := Q^{\beta-1} < 1/(2K + 3)$. Then $q_i/Q < \delta_0$, and it is plain (see also [ibid.]) that

$$\frac{q_{i+1}}{Q} > 1 - \delta_0, \quad \kappa\left( \frac{q_i}{Q}, \frac{q_{i+1}}{Q} \right) = 1,$$

and

$$\kappa\left( \frac{q_{i+1}}{Q}, \frac{q_{i+2}}{Q} \right) = \ldots = \kappa\left( \frac{q_{i+K}}{Q}, \frac{q_{i+K+1}}{Q} \right) = 2,$$

because $q_{i+1}, q_{i+2}, \ldots, q_{i+K+1}$ must form an arithmetic progression. Hence

$$\left( \frac{q_i}{Q}, \frac{q_{i+1}}{Q} \right) \in \mathcal{T}_1 \quad \text{and} \quad \left( \frac{q_{i+1}}{Q}, \frac{q_{i+2}}{Q} \right), \ldots, \left( \frac{q_{i+K}}{Q}, \frac{q_{i+K+1}}{Q} \right) \in \mathcal{T}_2,$$

showing in particular that $\min\{q_{i+1}, \ldots, q_{i+K}\} > Q/3$. Therefore, we find that $\max\{Q/q_{i+1}, \ldots, Q/q_{i+K}\} < 3$, and the contribution of this case to $N_{Q,\xi,\beta}$ is at most

$$\sum_{1 \leq q_- \leq Q^\beta} \sum_{1 \leq q_+ \leq Q^\beta} 4K \ll Q^{2\beta}.$$ 

(ii) $\gamma' \preccurlyeq \gamma$. Let $i$ be the unique index for which $\gamma_i < \Phi(\gamma) < \gamma_{i+1}$ with $\gamma_i < \gamma_{i+1}$ successive elements in $\mathcal{F}_Q$. Since $|\Phi(\gamma') - \Phi(\gamma)| \leq \xi/Q^2$, either $\gamma'_- < \Phi(\gamma') < \gamma'_+$ or there exists $0 \leq r \leq K$ with $\gamma'_+ = \gamma_{i-r}$ or with $\gamma'_- = \gamma_{i+r}$. In both situations the arc corresponding to the matrix $\gamma'$ will cross at least one of the vertical lines above $\gamma_i-K, \ldots, \gamma_i, \gamma_{i+1}, \ldots, \gamma_{i+K}$. A glance at the Farey tessellation provides an upper bound for this number $N_{\gamma',K}$ of arcs $\gamma' \in \mathcal{F}_Q$. Actually, one sees that the set $\mathcal{C}_{\gamma,L}$ consisting of $2 + 2^2 + \cdots + 2^L$ arcs obtained from $\gamma$ by iterating the
mediant construction \( L = [Q/\min\{q_-, q_+\}] + 1 \) times (\( \gamma \) is not enclosed in \( \bar{\mathcal{G}}_{\gamma, L} \)) contains the set \( \{ \gamma' \in \mathcal{R}_Q : \gamma' \preceq \gamma, \gamma' \neq \gamma \} \). The former set contains at most \( L \) arcs that are intersected by each vertical direction, and so \( N_{\gamma, K} \leq (2K + 1)L \). Therefore, the contribution of this case to \( \mathcal{N}_Q^\Phi \mathcal{F}, \xi, \beta \) is (first choose \( \gamma \), then \( \gamma' \)) at most

\[
\sum_{1 \leq q \leq Q^\beta} \sum_{1 \leq q' \leq Q^\beta} (2K + 1) \left( \frac{Q}{\min\{q, q'\}} + 1 \right) \ll \xi Q^{1+\beta} \ln Q.
\]

(iii) \( \gamma \preceq \gamma' \). We necessarily have \( \gamma = \gamma' M \), with \( M \in \mathcal{S} \). In particular, this yields \( \gamma_\pm \in \mathcal{F}_Q^\beta \). Considering the subtessellation defined only by arcs connecting points from \( \mathcal{F}_Q^\beta \), one sees that the number of arcs intersected by a vertical line \( x = \alpha \) with

\[
\gamma_- = \frac{p}{q} < \alpha < \gamma_+ = \frac{p'}{q'}, \quad \text{where } \gamma = (\gamma_-, \gamma_+) \in \mathcal{F}_Q^\beta,
\]

is equal to \( s(q, q') \), the sum of digits in the continued fraction expansion of \( q/q' < 1 \) when \( q < q' \), and respectively to \( s(q', q) \) when \( q' < q \). A result from [Yao and Knuth 1975] yields in particular that

\[
\sum_{0 < q < q' \leq Q^\beta} s(q, q') \ll Q^{2\beta} \ln^2 Q,
\]

and therefore

\[
\#\{ (\gamma, \gamma') \in \mathcal{R}_Q^2 : \gamma \preceq \gamma' \} \leq 1 + 2 \sum_{0 < q < q' \leq Q^\beta} s(q, q') \ll Q^{2\beta} \ln^2 Q.
\]

This completes the proof of the proposition. \( \square \)

Proposition 3 and inequalities (4-3) and (4-4) imply:

**Corollary 4.** For each \( \beta \in \left( \frac{2}{3}, 1 \right) \),

\[
\mathcal{R}_Q^\Phi(\xi) = \mathcal{R}_Q^\Phi(\xi + O_\xi (Q^{2-3\beta})) + \mathcal{R}_Q^\Phi(O_\xi (Q^{2-3\beta})) + O_\xi (Q^{1+\beta} \ln Q).
\]

5. A decomposition of the pair correlation of \( \{ \Phi(\gamma) \} \)

To estimate \( \mathcal{R}_Q^\Phi(\xi) \), recall the correspondence between elements of \( \mathcal{R}_Q \) and arcs in the Farey tessellation from the end of Section 3. We consider the following two possibilities for the arcs associated to a pair \( (\gamma, \gamma') \in \mathcal{R}_Q^2 \):

(i) One of the arcs corresponding to \( \gamma \) and \( \gamma' \) contains the other.

(ii) The arcs corresponding to \( \gamma \) and \( \gamma' \) are exterior (possibly tangent).

Denoting by \( R_Q^\cap(\xi) \) and \( R_Q^\cap(\xi) \) the number of pairs in each case, we have

\[
\mathcal{R}_Q^\Phi(\xi) = R_Q^\cap(\xi) + R_Q^\cap(\xi).
\]
5.1. One of the arcs contains the other. In this case we have either \( \gamma = \gamma' M \) or \( \gamma' = \gamma M \) with \( M \in \mathcal{S} \) (see also Figure 4). For each \( M \in \Gamma \) define
\[
\Xi_M(x, y) = \frac{x y (Y_M - X_M) + (x^2 - y^2) Z_M}{(x^2 + y^2)(x^2 X_M + y^2 Y_M + 2xy Z_M)},
\]
where \( X_M, Y_M, Z_M \) are defined in (3-1). For \( \gamma = \left( \frac{p'}{q'}, \frac{p}{q} \right) \), a direct calculation shows
\[
\Phi(\gamma) - \Phi(\gamma M) = \Xi_M(q', q).
\]
(5-2)

Two remarks are in order now. First, notice that \( X_M \neq Y_M \) for any \( M \in \mathcal{S} \) because of (3-2) and since \( X_M, Y_M, Z_M \geq 1 \). Secondly, we also have
\[
\Phi(\gamma) \neq \Phi(\gamma M).
\]
(5-3)

Suppose, ad absurdum, that \( \Phi(\gamma) = \Phi(\gamma M) \). Then (5-2) and (5-1) yield
\[
\frac{2Z_M}{Y_M - X_M} = \frac{2qq'}{q^2 - q'^2},
\]
that is, \( \tan \theta_M = \tan 2\theta \), where \( \theta = \tan^{-1}(q'/q) \in (0, \pi) \) and \( \theta_M \in (0, \pi) \) because \( Z_M > 0 \). This gives
\[
\frac{X_M - \epsilon_M}{Z_M} = \tan \left( \frac{\theta_M}{2} \right) = \tan \theta \in \mathbb{Q},
\]
hence \( \sqrt{(X_M + Y_M)^2 - 4} = X_M + Y_M - 2\epsilon_M \in \mathbb{Q} \), which is not possible because \( X_M + Y_M \geq 3 \).

From (5-2) and (5-3) we now infer:

**Lemma 5.** Using the notation introduced before Proposition 3, the number of pairs \((\gamma, \gamma') \in \hat{\mathbb{R}}_Q^2, \gamma \neq \gamma'\), with \( 0 \leq \Phi(\gamma) - \Phi(\gamma') \leq \xi/Q^2 \) and \( \gamma \preceq \gamma' \) or \( \gamma' \preceq \gamma \), is given by
\[
R_Q^0(\xi) = \# \left\{ (\gamma, \gamma M) \in \hat{\mathbb{R}}_Q^2 : \gamma = \left( \frac{p'}{q'}, \frac{p}{q} \right), M \in \mathcal{S}, |\Xi_M(q', q)| \leq \frac{\xi}{Q^2} \right\}.
\]
5.2. Exterior arcs. In this case we have $\gamma, \gamma' \in 3\mathbb{R}_Q, \gamma' \geq \gamma$. Let $\ell \geq 0$ be the number of Farey arcs in $\mathbb{F}_Q$ connecting the arcs corresponding to $\gamma, \gamma'$ (see Figure 5). In other words, writing $\gamma = \left( \frac{p_0}{q_0}, \frac{p_1}{q_1}, \ldots, \frac{p_\ell}{q_\ell} \right)$ and $\gamma' = \left( \frac{p'_{\ell+1}}{q_{\ell+1}}, \frac{p'_{\ell+2}}{q_{\ell+2}}, \ldots, \frac{p'_{2\ell}}{q_{2\ell}} \right)$, we have that $p_{\ell-1}/q_{\ell-1} := p'/q'$, $p_{\ell}/q_{\ell}, \ldots, p_{2\ell}/q_{2\ell}$ are consecutive elements in $\mathbb{F}_Q$. Setting also $p_{\ell-1}/q_{\ell-1} := p/q$, it follows that $q_i = k_i q_{i-1} - q_{i-2}$, where $k_i \in \mathbb{N}$, $i = 1, \ldots, \ell$, and

$$k_i = \left[ \frac{Q + q_{i-2}}{q_{i-1}} \right] \quad \text{for} \quad 2 \leq i \leq \ell.$$  

The fractions $p_{\ell}/q_{\ell}$ and $p_{\ell+1}/q_{\ell+1}$ are not necessarily consecutive in $\mathbb{F}_Q$, but we have $q_{\ell+1} = K q_{\ell} - q_{\ell-1}$, 

$$K \leq k_{\ell+1} = \left[ \frac{Q + q_{\ell}}{q_{\ell+1}} \right].$$

It follows that $\gamma' = \gamma M$ with 

$$M = \begin{pmatrix} k_1 & 1 \\ -1 & 0 \end{pmatrix} \cdots \begin{pmatrix} k_{\ell} & 1 \\ -1 & 0 \end{pmatrix} \left( \begin{array}{cc} K & 1 \\ 1 & 0 \end{array} \right).$$

We have $\ell < \xi$ because

$$\Phi(\gamma') - \Phi(\gamma) > \sum_{i=1}^{\ell} \frac{1}{q_{i-1} q_i} \geq \frac{\ell}{Q^2}.$$  

It is also plain to see that

$$\frac{p'_{\ell}}{q'} - \Phi(\gamma) = \frac{q}{q'(q^2 + q'^2)}, \quad \Phi(\gamma') - \frac{p_{\ell}}{q_{\ell}} = \frac{q_{\ell+1}}{q_{\ell}(q_{\ell}^2 + q_{\ell+1}^2)}. \quad (5-4)$$

The last equality in (5-4) and $q_{\ell}^2 + q_{\ell+1}^2 \leq Q^2$ yield, for $\ell \geq 1$,

$$\frac{\xi}{Q^2} \geq \Phi(\gamma') - \Phi(\gamma) \geq \frac{1}{q_{\ell-1} q_{\ell}} + \frac{q_{\ell+1}}{q_{\ell}(q_{\ell}^2 + q_{\ell+1}^2)}$$

$$\geq \frac{1}{q_{\ell-1} q_{\ell}} + \frac{K q_{\ell} - q_{\ell-1}}{q_{\ell} Q^2} = \frac{K}{Q^2} + \frac{Q^2 - q_{\ell-1}^2}{q_{\ell-1} q_{\ell} Q^2} \geq \frac{K}{Q^2},$$

while if $\ell = 0$ we have

$$\Phi(\gamma') - \Phi(\gamma) = \frac{K(q^2 + q_1)}{(q^2 + q'^2)(q^2 + q_1^2)} \geq \frac{K}{Q^2},$$
showing that $K < \xi$. Notice also that (5-4) yields

$$
\Phi(\gamma') - \Phi(\gamma) = \frac{q}{q'(q^2 + q'^2)} + \sum_{i=1}^{\ell} \frac{1}{q_{i-1}q_i} + \frac{q_{\ell+1}}{q_\ell(q_\ell^2 + q_\ell'^2)}.
$$

Let $\mathcal{T} = \{(x, y) \in (0, 1]^2 : x + y > 1\}$ and consider the map

$$
T : (0, 1]^2 \to \mathcal{T}, \quad T(x, y) = \left( y, \left[ \frac{1+x}{y} \right] y - x \right),
$$

whose restriction to $\mathcal{T}$ is bijective and area-preserving [Boca et al. 2001]. Consider the iterates $T^i = (L_{i-1}, L_i)$ and the functions $K_i = [(1+L_{i-2})/L_{i-1}]$ if $i = 1, \ldots, \ell$, $K_{\ell+1} = K$, and $L_{\ell+1} = K L_\ell - L_{\ell-1}$. One has:

- $L_{i-1}(x, y) = x$ and $L_0(x, y) = y$ for $(x, y) \in (0, 1]^2$;
- $0 < L_i(x, y) \leq 1$ for $i \geq 0$ and $(x, y) \in \mathcal{T}$;
- $L_{i-1}(x, y) + L_i(x, y) > 1$ for $i = 1, \ldots, \ell$ and $(x, y) \in \mathcal{T}$;
- $L_i(x, y) = K_i(x, y)L_{i-1}(x, y) - L_{i-2}(x, y)$
  for $i = 1, \ldots, \ell+1$ and $(x, y) \in \mathcal{T}$;

$$
(q_{i-1}, q_i) = QT^i\left(\frac{q}{Q}, \frac{q'}{Q}\right) = \left(QL_{i-1}\left(\frac{q}{Q}, \frac{q'}{Q}\right), QL_i\left(\frac{q}{Q}, \frac{q'}{Q}\right)\right) \text{ for } i = 0, 1, \ldots, \ell;
$$

$$
q_{\ell+1} = Kq_\ell - q_{\ell-1} = Q\left(KL_\ell\left(\frac{q}{Q}, \frac{q'}{Q}\right) - L_{\ell-1}\left(\frac{q}{Q}, \frac{q'}{Q}\right)\right).
$$

Define also the function $\Upsilon_{\ell,K} : (0, 1]^2 \to (0, \infty)$ by

$$
\Upsilon_{\ell,K} = \frac{L_{i-1}}{L_0(L_{i-1}^2 + L_0^2)} + \sum_{i=1}^{\ell} \frac{1}{L_{i-1}L_i} + \frac{L_{\ell+1}}{L_\ell(L_\ell^2 + L_{\ell+1}^2)}.
$$

We have proved the following statement:

**Lemma 6.** The number $R_Q^{\cap \cap}(\xi)$ of pairs $(\gamma, \gamma')$ of exterior (possibly tangent) arcs in $\tilde{\mathcal{R}}_Q$ for which $0 < \Phi(\gamma') - \Phi(\gamma) \leq \xi/Q^2$ is given by

$$
R_Q^{\cap \cap}(\xi) = \sum_{\ell \in [0, \xi)} \sum_{K \in [1, \xi)} d_{\ell K},
$$

where the sums are over integers in the given intervals, $d_{\ell K}$ is the number of matrices

$$
\left(\begin{array}{cc}
p' & p \\ q' & q
\end{array}\right)
$$

such that the following hold:
Weil’s estimates [1948] on Kloosterman sums, extended to composite moduli (for a proof see [Narkiewicz 1983, Theorem 5.9]) we find that the number of replacing

\begin{align}
0 \leq p \leq q, & \quad 0 \leq p' \leq q', \quad p'q - pq' = 1, \\
p^2 + p'^2 + q^2 + q'^2 \leq Q^2, & \quad 0 < Kq_\ell - q_{\ell-1} \leq Q, \\
p_\ell^2 + q_\ell^2 + (Kp_\ell - p_{\ell-1})^2 + (Kq_\ell - q_{\ell-1})^2 \leq Q^2,
\end{align}

\hspace{1cm} \gamma_{\ell,K}(q/Q, q'/Q) \leq \xi,

and \( q_{-1} = q, q_0 = q' \).

6. A lattice point estimate

\textbf{Lemma 7.} Suppose that \( \Omega \) is a region in \( \mathbb{R}^2 \) of area \( A(\Omega) \) and rectifiable boundary of length \( \ell(\partial \Omega) \). For any integer \( r \) with \( (r, q) = 1 \) and \( 1 \leq L \leq q \), we have

\[ N_{\Omega,q,r} := \# \{(a, b) \in \Omega \cap \mathbb{Z}^2 : ab \equiv r \pmod{q} \} = \frac{\varphi(q)}{q^2} A(\Omega) + \mathcal{E}_{\Omega,L,q}, \]

where, for each \( \varepsilon > 0 \),

\[ \mathcal{E}_{\Omega,L,q} \ll \varepsilon \frac{q^{1/2+\varepsilon} A(\Omega)}{L^2} + \left( 1 + \frac{\ell(\partial \Omega)}{L} \right) \left( \frac{L^2}{q} + q^{1/2+\varepsilon} \right). \]

\textbf{Proof.} Replacing \( \mathbb{Z}^2 \) by \( L \mathbb{Z}^2 \) in the estimate

\[ \{(m, n) \in \mathbb{Z}^2 : (m, m+1) \times (n, n+1) \cap \partial \Omega \neq \emptyset \} \ll 1 + \ell(\partial \Omega), \]

(for a proof see [Narkiewicz 1983, Theorem 5.9]) we find that the number of squares \( S_{m,n} = [Lm, L(m+1)] \times [Ln, L(n+1)] \) such that \( \partial S_{m,n} \cap \partial \Omega \) is nonempty is \( \ll 1 + (1/L)\ell(\partial \Omega) \).

Therefore

\[ \# \{(m, n) \in \mathbb{Z}^2 : (Lm, L(m+1)) \times (Ln, L(n+1)) \subseteq \Omega \} = \frac{A(\Omega)}{L^2} + O\left( 1 + \frac{\ell(\partial \Omega)}{L} \right). \]

Weil’s estimates [1948] on Kloosterman sums, extended to composite moduli in [Hooley 1957] and [Estermann 1961], show that each such square contains \( (\varphi(q)/q^2)L^2 + O_\varepsilon(q^{1/2+\varepsilon}) \) pairs of integers \( (a, b) \) with \( ab \equiv r \pmod{q} \) (see, e.g., [Boca et al. 2000, Lemma 1.7] for details). Combining these two estimates, we find

\[ N_{\Omega,q,r} = \left( \frac{A(\Omega)}{L^2} + O\left( 1 + \frac{\ell(\partial \Omega)}{L} \right) \right) \left( \frac{\varphi(q)}{q^2} L^2 + O(q^{1/2+\varepsilon}) \right) = \frac{\varphi(q)}{q^2} A(\Omega) + \mathcal{E}_{\Omega,q,L}, \]

as desired. \( \square \)

\textbf{Corollary 8.}

\[ \#\widehat{\mathcal{R}}_Q = \frac{3Q^2}{8} + O_\varepsilon(Q^{11/6+\varepsilon}). \]

\textbf{Proof.} Note first that one can substitute \( pq'/q \) for \( p' = (1 + pq')/q \) in the definition of \( \widehat{\mathcal{R}}_Q \), replacing the inequality \( \|y\|^2 \leq Q^2 \) by \( (q^2 + q'^2)(q^2 + p^2) \leq Q^2 q^2 \), without altering the error term. Applying Lemma 7 with

\[ \Omega_q = \{(u, v) \in [0, q] \times [0, Q] : (q^2 + u^2)(q^2 + v^2) \leq Q^2 q^2 \} \quad \text{and} \quad L = q^{5/6}, \]
and using \( A(\Omega_q) \leq Qq \) and \( \ell(\Omega_q) \leq 2(Q + q) \leq 4Q \), we infer that

\[
\#\tilde{\mathcal{R}}_Q = \sum_{q=1}^{Q} \frac{\varphi(q)}{q} \cdot \frac{A(\Omega_q)}{q} + O_\varepsilon(Q^{11/6+\varepsilon}).
\]

Standard Möbius summation (see, e.g., [Boca et al. 2000, Lemma 2.3]) applied to the decreasing function \( h(q) = (1/q)A(\Omega_q) \) with \( \|h\|_\infty \leq Q \) and the change of variable \((q, u, v) = (Qx, Qxy, Qz)\) further yield

\[
\#\tilde{\mathcal{R}}_Q = \frac{Q^2}{\xi(2)} \text{Vol}(S) + O_\varepsilon(Q^{11/6+\varepsilon}),
\]

where \( S = \{(x, y, z) \in [0, 1]^3 : (1 + y^2)(x^2 + z^2) \leq 1\} \).

The substitution \( y = \tan \theta \) yields

\[
\text{Vol}(S) = \int_0^{\pi/4} \frac{d\theta}{\cos^2 \theta} A\left(\{(x, z) \in [0, 1]^2 : x^2 + z^2 \leq \cos^2 \theta\}\right) = \frac{\pi^2}{16},
\]

completing the proof of the corollary. \( \Box \)

The error bound in Corollary 8 can be improved using spectral methods (see Corollary 12.2 in [Iwaniec 2002]). We have given the proof since it is the prototype of applying Lemma 7 to the counting problems of the next section.

### 7. Pair correlation of \( \{\Phi(\gamma)\} \)

The main result of this section is Theorem 2, where we obtain explicit formulas for the pair correlation of the quantities \( \{\Phi(\gamma)\} \) in terms of volumes of three-dimensional bodies. The discussion is divided in two cases, as in Section 5.

#### 7.1. One of the arcs contains the other

The formula for \( R_Q^\otimes \) in Lemma 5 provides

\[
R_Q^\otimes(\xi) = \sum_{M \in \mathcal{S}} \mathcal{N}_{M, Q}(\xi), \tag{7-1}
\]

where \( \mathcal{N}_{M, Q}(\xi) \) denotes the number of matrices \( \gamma = \begin{pmatrix} p' & p \\ q' & q \end{pmatrix} \) for which

\[
0 \leq p \leq q, \quad 0 \leq p' \leq q', \quad p'q - pq' = 1, \quad |\Xi_M(q', q)| \leq \frac{\xi}{Q^2}, \quad \|\gamma M\| \leq Q. \tag{7-2}
\]

The first goal is to replace in (7-2) the inequality \( \|\gamma M\| \leq Q \) by a more tractable one. Taking \( \gamma \) of the given form and substituting \( p = (p'q - 1)/q' \) we write, using the notation from (3-1):

\[
\|\gamma M\|^2 = \left(\frac{p'^2}{q'^2} + 1\right) \left(q'^2 X_M + q^2 Y_M + 2qq'Z_M\right) - \frac{(p'q + pq')Y_M + 2p'q'Z_M}{q^2}. \tag{7-3}
\]
The quantity $\mathcal{N}_M, Q(\xi)$ can be conveniently related to $\tilde{\mathcal{N}}_M, Q(\xi)$, the number of integer triples $(q', q, p')$ such that

$$0 < p' \leq q' \leq Q, \quad 0 < q \leq Q, \quad p'q \equiv 1 \pmod{q'},$$

$$|\Xi_M(q', q)| \leq \frac{\xi}{Q^2}, \quad Y_M = q^2 X_M + q^2 Y_M + 2qq' Z_M \leq \frac{Q^2 q'^2}{p'^2 + q'^2}. \quad (7-4)$$

We next prove that, given $c_0 \in \left(\frac{1}{2}, 1\right)$, for all $M \in \mathcal{S}$ and $Q \geq 1$ with $Y_M < X_M \leq Q^{2c_0}$ and all $\xi > 0$,

$$\tilde{\mathcal{N}}_{M, Q}(\xi) \leq \mathcal{N}_{M, Q}(\xi) \leq \tilde{\mathcal{N}}_{M, Q(1 + \sqrt{2}Q^{c_0 - 1})}(\xi(1 + \sqrt{2}Q^{c_0 - 1})^2). \quad (7-5)$$

For the first inequality, note that if the integral triple $(q', q, p')$ satisfies (7-4) then by (7-3) we have

$$\|Y_M\|^2 \leq \frac{p'^2 + q'^2}{q'^2} Y_M \leq Q^2,$$

and thus if we define $p := (p'q - 1)/q'$ then (7-2) holds. For the second inequality, take $\gamma$ as in (7-2). Using (7-3) we then have

$$\frac{p'^2 + q'^2}{q'^2} Y_M \leq Q^2 + \frac{(p'q + pq') Y_M + 2p'q' Z_M}{q'^2} \leq Q^2 + 2qY_M + 2Z_M.$$

Using also that $Z_M \leq Q^{2c_0}$ and $qY_M = \sqrt{q^2 Y_M} \sqrt{X_M} \leq \sqrt{Y_M} \sqrt{Y_M} \leq Q^{1+c_0}$, we conclude that

$$\frac{p'^2 + q'^2}{q'^2} Y_M \leq Q^2 + 2Q^{1+c_0} + 2Q^{2c_0} \leq Q^2(1 + \sqrt{2}Q^{c_0 - 1})^2.$$

Also

$$|\Xi_M(q', q)| \leq \frac{\xi}{Q^2} = \frac{\xi(1 + \sqrt{2}Q^{c_0 - 1})^2}{Q^2(1 + \sqrt{2}Q^{c_0 - 1})^2}.$$

Hence $(q', q, p')$ satisfies (7-4) with the pair $(Q, \xi)$ replaced by $(Q + \sqrt{2}Q^{c_0}, \xi(1 + \sqrt{2}Q^{c_0 - 1})^2)$. This proves (7-5).

Next we show that $\mathcal{N}_{M, Q}(\xi)$ vanishes when $\max\{X_M, Y_M\} \geq Q^{2c_0}$ and $Q$ is large enough.

**Lemma 9.** Let $c_0 \in \left(\frac{1}{2}, 1\right)$. There exists $Q_0(\xi)$ such that whenever $M \in \mathcal{S}$, $\max\{X_M, Y_M\} \geq Q^{2c_0}$, and $Q \geq Q_0(\xi)$,

$$\mathcal{N}_{M, Q}(\xi) = \tilde{\mathcal{N}}_{M, Q}(\xi) = 0.$$

**Proof.** We show there are no coprime positive integer lattice points $(q', q)$ for which

$$|\Xi_M(q', q)| \leq \frac{\xi}{Q^2}, \quad Y_M = q^2 X_M + q^2 Y_M + 2qq' Z_M \leq Q^2. \quad (7-6)$$
Noting from (7-3) that $Y_{\gamma M} \leq \|Y M\|^2$, this will ensure that $N_{M,Q}(\xi) = 0$. The equality $\tilde{N}_{M,Q}(\xi) = 0$ follows as well from (7-4).

Suppose $(q', q)$ is as in (7-6), write $q' + q = (q, q') = (r \cos \theta, r \sin \theta)$, $\theta \in (0, \pi/2)$, and consider $(X, Y, Z) = (X_M, Y_M, Z_M)$, $T = \|M\|^2 = X + Y$, and $U_M = \coth d(i, Mi) = T/\sqrt{T^2 - 4}$. Since
\[
\sin \theta_M = \frac{2Z}{\sqrt{T^2 - 4}} \quad \text{and} \quad \cos \theta_M = \frac{Y - X}{\sqrt{T^2 - 4}},
\]
the inequalities in (7-6) can be described as
\[
\frac{1}{\xi} \cdot \frac{|\sin(\theta_M - 2\theta)|}{U_M + \cos(\theta_M - 2\theta)} \leq \frac{r^2}{Q^2} \leq \frac{2}{(U_M + \cos(\theta_M - 2\theta))\sqrt{T^2 - 4}}. \tag{7-7}
\]

Denoting $\delta_M = \theta_M/2 - \theta$, from the first and last fraction in (7-7) we infer $|\sin 2\delta_M| \ll 1/T$. Therefore $\delta_M$ is close to 0, or to $\pm \pi/2$. When $\delta_M$ is close to 0 we have
\[
|\tan \delta_M| \ll |\delta_M| \ll |\sin 2\delta_M| \ll \frac{1}{T}.
\]

When $\delta_M$ is close to $\pm \pi/2$ we similarly have $|\delta_M \mp \pi/2| \ll \frac{1}{T}$, which is seen to be impossible. Indeed, the inequality
\[
\frac{|\tan \delta_M|}{1 + \frac{U_M - 1}{1 + \cos 2\delta_M}} = \frac{|\sin 2\delta_M|}{U_M + \cos 2\delta_M} \leq \xi
\]
shows that it suffices to bound from above $(U_M - 1)/(1 + \cos 2\delta_M)$, which would imply that $|\tan \delta_M| \ll \xi$, thus contradicting $|\delta_M \mp \pi/2| \ll 1/T$. Since $Z$ is a positive integer, we have $\sin \theta_M \gg 1/T$. Since $\cos \theta$, $\sin \theta > 0$ and $\theta_M \in (0, \pi)$, we have
\[
1 + \cos 2\delta_M = 1 + \cos(\theta_M - 2\theta) \geq 1 + \cos 2\theta \cos \theta_M
\geq 1 - \cos \theta_M = 1 - \sqrt{1 - \sin^2 \theta_M} \gg \frac{1}{T^2}.
\]
As $U_M - 1 \ll 1/T^2$, it follows that $(U_M - 1)/(1 + \cos 2\delta_M) \ll 1$, a contradiction.

We have thus shown that $|\delta_M| \ll |\tan \delta_M| \ll 1/T$; more precisely, there exists a function $\Theta_0(\xi)$, continuous in $\xi$, such that $|\delta_M| \leq \Theta_0(\xi)/T$.

**Case I:** $Y > X$. Then $0 < \theta_M/2 < \pi/4$ and $Z = \sqrt{XY - 1} < Y$. Since
\[
|\delta_M| \ll \frac{1}{T} \ll Q^{-2c_0},
\]
one has $0 < \theta < \pi/3$ for large $Q$. Employing the formula $\tan(\theta_M/2) = Z/(Y - \epsilon_T)$ with $\epsilon_T$ as in (3-1), we infer
\[
\left| \frac{AC + BD}{C^2 + D^2 - \epsilon_T} - \frac{q'}{q} \right| = |\tan \delta_M| \cdot \left| 1 + \tan \theta \tan \frac{\theta_M}{2} \right| \ll \frac{1}{T}. \tag{7-8}
\]
Combining (7-8) with
\[0 < \frac{Z}{Y - \varepsilon_T} - \frac{Z}{Y} \ll \frac{1}{T}\] and \[|Z - \frac{A + B}{C + D}| \leq \frac{1}{C^2 + D^2} \ll \frac{1}{T},\]
we arrive at
\[\left| \frac{A + B}{C + D} - q' \right| \ll \frac{1}{T} \leq Q^{-2c_0}. \tag{7-9}\]

If nonzero, the left-hand side in (7-9) must be at least \(1/q(C + D)\). But
\[q(C + D) \leq q\sqrt{2(C^2 + D^2)} \leq Q\sqrt{2},\]
and so \(Q^{2c_0} \ll Q\), a contradiction. The remaining case, in which \(q = C + D\) and \(q' = A + B\), is not possible because \(Q^{2c_0} \leq (C + D)^2 = q(C + D) \leq Q\sqrt{2}\).

**Case II:** \(X > Y\). Then \(\pi/4 < \theta_M/2 < \pi/2\) and \(Y = \sqrt{XY - 1} = Z\). As \(|\delta_M| \ll Q^{-2c_0}\), we must have \(0 < \pi/2 - \theta < \pi/3\) for large values of \(Q\). This time we have
\[\left| \frac{Y - \varepsilon_T}{Z} - \frac{q'}{q} \right| = \left| \tan \left( \frac{\pi}{2} - \frac{\theta}{2M} \right) - \tan \left( \frac{\pi}{2} - \theta \right) \right| = |\tan \delta_M| \cdot \left| 1 + \tan \left( \frac{\pi}{2} - \frac{\theta}{2M} \right) \tan \left( \frac{\pi}{2} - \theta \right) \right| \leq (1 + \sqrt{3}) |\tan \delta_M| \ll \frac{1}{T},\]
which leads (since \(D \geq C\) if and only if \(B \geq A\)) to
\[\left| \frac{C + D}{A + B} - q' \right| \ll \frac{1}{T} + \frac{\varepsilon_T}{Z} + \left| \frac{Y}{Z} - \frac{C + D}{A + B} \right| \ll \frac{1}{T} + \frac{|D - C|}{(A + B)(AC + BD)} \leq \frac{1}{T} + \frac{1}{(A + B)^2} \ll \frac{1}{T} \leq Q^{-2c_0}. \tag{7-10}\]

As in Case I, this is not possible because \(q'(A + B) \leq q'\sqrt{2X} \leq Q\sqrt{2}\) and \((A + B)^2 \gg Q^{2c_0}\).

Our next goal is to apply Lemma 7, assuming \(Y_M < X_M \ll Q^{2c_0}\) and taking \(r = 1\), to the set \(\Omega = \Omega_{M,q',\xi}\) of pairs \((u, v) \in (0, Q] \times (0, q']\) that satisfy
\[|\Xi_M(q', u)| \leq \frac{\xi}{Q^2} \quad \text{and} \quad q'^2 X_M + u'^2 Y_M + 2uq' Z_M \leq \frac{Q^2 q'^2}{u'^2 + q'^2}. \tag{7-11}\]

**Lemma 10.** There exist continuous functions \(T_0(\xi)\) and \(C(\xi)\) such that, for any matrix \(M \in \mathcal{S}\) with \(Y_M < X_M \ll Q^{2c_0}\) and \(T = \|M\|^2 > T_0(\xi)\), the projection on the first coordinate of the set \(\Omega_{M,q',\xi}\) is contained in the interval \((0, C(\xi)q')\).

**Proof.** Using polar coordinates \((u, q') = (r \cos \theta, r \sin \theta), \theta \in (0, \pi/2)\), we see that inequalities (7-11) imply (7-7). This shows that for the purpose of this lemma we can replace \(\Omega_{M,q',\xi}\) by the set of \((u, v) \in (0, Q] \times (0, q']\) satisfying (7-7). Therefore we can use all estimates from the first part of the proof of Lemma 9 (because they only rely on (7-7), the integrality of \(q\) being used only at the end).
Note also that \( Y = Y_M < X = X_M \) and \( Z^2 = XY - 1 \) yield \( Y \leq Z \). Replacing \( q \) by \( u \) in the first part of the proof of Lemma 9, so that \( \tan \theta = u/q' \), \( \theta \in (0, \pi/2) \), we see (compare the last line before Case 1) that \( |\delta_M| \leq \Theta(\xi)/T \) for some continuous function \( \Theta \). Next we look into the first estimates in Case 2 and see that there exists a function \( T_0(\xi) \), depending continuously on \( \xi \), such that, for any \( M \) with \( T = \|M\|^2 > T_0(\xi) \), one has \( 0 < \pi/2 - \theta < \pi/3 \) and

\[
\left| \frac{u}{q'} - \frac{Y - \epsilon_T}{Z} \right| \leq (1 + \sqrt{3}) |\tan \delta_M|.
\]

In conjunction with the bound on \( \delta_M \), this shows the existence of a continuous function \( C_0(\xi) \) such that

\[
|u - \frac{Y - \epsilon_T}{Z}q'| \leq C_0(\xi)q',
\]

showing that \( u \leq (1 + C_0(\xi))q' \).

Although this will not be used in this paper, we remark that if \( \gamma \) is as in (7-2), then (7-4) is satisfied by the triple \((q', q, p')\) with the pair \((Q, \xi)\) replaced by \((Q + \sqrt{2}Q^{c_0}, \xi(1 + \sqrt{2}Q^{c_0-1})^2)\), by the proof of (7-5). Therefore Lemma 10 shows that \( q/q' \ll \xi \) with a different implicit constant than \( C(\xi) \) from Lemma 10.

Next notice that, as \( Q \to \infty \),

\[
\sum_{\max\{X_M, Y_M\} \leq Q^{2c_0}} \max\{X_M, Y_M\}^{-\sigma} \ll_{\sigma} Q^{(2-2\sigma)c_0}, \quad 0 < \sigma < 1. \tag{7-12}
\]

This follows immediately from\(^1\)

\[
\sum_{\max\{X_M, Y_M\} \leq Q^{2c_0}} X_M^{-\sigma} \leq \sum_{1 \leq A^2 + B^2 \leq Q^{2c_0}} (A^2 + B^2)^{-\sigma} \leq \iint_{x^2 + y^2 \leq 2Q^{2c_0}} (x^2 + y^2)^{-\sigma} \, dx \, dy \ll_{\sigma} Q^{(2-2\sigma)c_0}.
\]

Assume now that \( Y_M < X_M \leq Q^{2c_0} \). When \( T = \|M\|^2 > T_0(\xi) \) we apply Lemma 10. The definition of \( \Omega \), seen after some obvious scaling as a section subset in the body \( S_{M, \xi} \) defined by the conditions in (7-14) below, shows that the range of \( u \) consists of a union of intervals in \([0, Q]\) with a (universally) bounded number of components and of total Lebesgue measure \( \ll_{\xi} q' \). This gives

\[
A(\Omega) \ll_{\xi} \frac{Qq'}{\sqrt{X_M}} \quad \text{and} \quad \ell(\partial \Omega) \ll_{\xi} q' + q' \ll \frac{Q}{\sqrt{X_M}}.
\]

\(^1\)Here \( A \) and \( B \) determine uniquely the matrix \( M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \).
Taking \( L = (q')^{5/6} \), we find \( Q \gg X_M^{1/2} (q')^{1/6} \), and the error provided by Lemma 7 is \( \varepsilon_{\Omega, L \cdot q'} \ll Q(q')^{-1/6+\varepsilon}X_M^{-1/2} \). Note also that in this case \( A \geq C \) and \( B \geq D \). As a result, applying (7-12) with \( \sigma = \frac{11}{12} \), the error is seen to add up to

\[
\sum_{A^2+B^2 \leq Q^{2\varepsilon_0}} \sum_{\|M\|^2 > T_0(\xi)} \varepsilon_{\Omega, q^{5/6}, q'} \ll Q \sum_{A^2+B^2 \leq Q^{2\varepsilon_0}} \frac{1}{X_M^{1/2}} \left( \frac{Q}{X_M^{1/2}} \right)^{5/6+\varepsilon} \ll Q(11+c_0)/6+\varepsilon.
\]

Lemma 7 now provides

\[
\widetilde{\mathcal{N}}_M(Q, \xi) = \sum_{1 \leq q' \leq Q/\sqrt{X_M}} \frac{\varphi(q')}{q'^2} A(\Omega_M, q', \xi) + O( Q(11+c_0)/6+\varepsilon ). \tag{7-13}
\]

The situation \( \|M\|^2 \leq T_0(\xi) \) (in this case there are \( O_\xi(1) \) choices for \( M \)) is directly handled by Lemma 7. The same choice for \( L \) provides \( \varepsilon_{\Omega, q^{5/6}, q'} \ll Q(q')^{-1/6+\varepsilon} \). These error terms sum up to \( O_{\xi, \varepsilon}(Q^{11/6+\varepsilon}) \) in this situation.

Next we will apply Möbius summation (see, e.g., [Boca et al. 2000, Lemma 2.3]) to the function \( h_1(q') = (1/q')A(\Omega_M, q', \xi) \). Note that \( (1/Q)h_1(q') \) represents the area of the cross-section of the body \( S_{M, \xi} \) by the plane \( x = q'/Q \), where \( S_{M, \xi} \) consists of those \((x, y, z) \in [0, 1]^3 \) such that

\[
|\Xi_M(x, y)| \leq \xi \quad \text{and} \quad x^2X_M + y^2Y_M + 2xyZ_M \leq \frac{1}{1+\xi^2}. \tag{7-14}
\]

The intersection of the projection of \( S_{M, \xi} \) onto the plane \( z = 0 \) with a vertical line \( x = c \) is bounded by a quartic and an ellipse, showing that the cross-section function \( c \mapsto A_{M, \xi}(c) : = \text{Area}(S_{M, \xi} \cap \{x = c\}) \) is continuous and piecewise \( C^1 \) on \([0, 1]\) and the number of critical points of \( A_{M, \xi} \) is bounded by a universal constant \( C \) independently of \( M \) and \( \xi \). The graph on the right of Figure 6 illustrates one of the possible cases that can arise, when \( A_{M, \xi}(c) \) has the most number of critical points, showing that we can take \( C = 3 \).

In particular, the total variation of \( h_1 \) on \([0, Q]\) is bounded above by

\[
(C+1)(\sup_{[0, Q]} h_1 - \inf_{[0, Q]} h_1) \ll \|h_1\|_\infty \ll \frac{Q}{\sqrt{X_M}},
\]

and so we infer

\[
\sum_{1 \leq q' \leq Q/\sqrt{X_M}} \frac{\varphi(q')}{q'^2} A(\Omega_M, q', \xi) = \frac{1}{\xi(2)} \int_0^{Q/\sqrt{X_M}} h_1(q') dq' + O\left( \frac{Q}{\sqrt{X_M}} \ln Q \right).
\]

Using also the change of variables \((q', u, v) = (Qx, Qy, Qxz), (x, y, z) \in [0, 1]^3\),
Figure 6. Left: cross-sections of $S_{M, \xi}$ for $z = 0$ (vertical hatching) and $z = 1$ (horizontal hatching). Right: the function $c \mapsto A_{M, \xi}(c)$, for $M = R$ and $\xi = 1.5$.

(7-13), (7-5) and (7-12), we find that the contribution to $R_Q^\otimes(\xi)$ of matrices $M$ with $Y_M < X_M$ is

$$\frac{1}{\zeta(2)} \sum_{M \in \mathcal{S}} \left( \int_0^{Q} A_{M, q', \xi} \frac{dq'}{q'} + O\left( \frac{Q \ln Q}{X_M^{1/2}} \right) \right) + O_{\varepsilon, \xi}(Q^{(11+c_0)/6+\varepsilon})$$

$$= \frac{Q^2}{\zeta(2)} \sum_{M \in \mathcal{S}} \text{Vol}(S_{M, \xi}) + O_{\varepsilon, \xi}(Q^{1+c_0+\varepsilon} + Q^{(11+c_0)/6+\varepsilon}). \quad (7-15)$$

With $\eta = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, notice the following important symmetries:

$$\eta M \eta = \begin{pmatrix} D & C \\ B & A \end{pmatrix} \quad \text{and} \quad \Xi_{\eta M \eta}(y, x) = -\Xi_M(x, y). \quad (7-16)$$

This shows that the reflection $(x, y, z) \mapsto (y, x, z)$ maps $S_{M, \xi}$ bijectively onto $S_{\eta M \eta, \xi}$.

The situation $X_M < Y_M$ is handled similarly using (7-16), which results in reversing the roles of $q$ and $q'$ with Lemma 7 applied for $r = -1$.

Now we give upper bounds for $\text{Vol}(S_{M, \xi})$. Let $(x, y, z) = (r \cos t, r \sin t, z) \in S_{M, \xi}$. The proof of (7-9) and (7-10) does not use the integrality of $q'$ and $q$, so denoting

$$\omega_M = \frac{C+D}{A+B} < 1 \quad \text{if} \quad Y_M < X_M \quad \text{and} \quad \omega_M = \frac{A+B}{C+D} < 1 \quad \text{if} \quad X_M < Y_M,$$

we find that

$$y \ll x \ll X_M^{-1/2} \ll T^{-1} \quad \text{and} \quad \left| \frac{y}{x} - \omega_M \right| \ll \frac{1}{T}$$

in the former case, and

$$x \ll y \ll Y_M^{-1/2} \ll T^{-1} \quad \text{and} \quad \left| \frac{x}{y} - \omega_M \right| \ll \frac{1}{T}$$
in the latter case. Writing the area in polar coordinates, we find $r^2 \ll T^{-1}$ and

$$\text{Vol}(S_M, \xi) \leq A\left(\{(x, y) \in [0, 1]^2 : \exists z \in [0, 1], (x, y, z) \in S_M, \xi\}\right) \leq \frac{1}{2} \int_{\omega_M - \xi T_M^{-1}}^{\omega_M + \xi T_M^{-1}} 2T_M^{-1} \, dt = \frac{2\xi}{T_M^2} = \frac{2\xi}{\|M\|^4}. \quad (7-17)$$

The bound (7-17) and an argument similar to the proof of (7-12) yields

$$\sum_{M \in \mathcal{S}} \text{Vol}(S_M, \xi) < \infty \quad \text{and} \quad \sum_{M \in \mathcal{S}} \text{Vol}(S_M, \xi) \ll \xi^{-2c_0}. \quad (7-18)$$

From (7-15), (7-18) and $c_0 \in \left(\frac{1}{2}, 1\right)$, we infer

$$R_Q^{\xi}(\xi) = \frac{Q^2}{\xi(2)} \sum_{M \in \mathcal{S}} \text{Vol}(S_M, \xi) + O_\xi(Q^{(11+6)/6+\varepsilon}). \quad (7-19)$$

The volume of $S_M, \xi$ can be evaluated in closed form using the substitution $z = \tan t$:

$$\text{Vol}(S_M, \xi) = \int_0^{\pi/4} B_M(\xi, t) \frac{dt}{\cos^2 t}, \quad (7-20)$$

where $B_M(\xi, t)$ is the area of the region consisting of those $(r \cos \theta, r \sin \theta) \in [0, 1]^2$ such that

$$\frac{1}{\xi} \cdot \frac{|\sin(2\theta - \theta_M)|}{U_T + \cos(2\theta - \theta_M)} \leq r^2 \leq \frac{1}{\sqrt{T^2 - 4}} \cdot \frac{2\cos^2 t}{U_T + \cos(2\theta - \theta_M)}, \quad (7-21)$$

with $\theta_M \in (0, \pi/2)$ having $\sin \theta_M = 2Z_M/\sqrt{T^2 - 4}$ and $U_T = T/\sqrt{T^2 - 4}$ (for brevity we write $T = T_M$).

The following elementary fact will be useful to prove the differentiability of the volumes as functions of $\xi$.

**Lemma 11.** Assume that $G, H : K \to \mathbb{R}$ are continuous functions on a compact set $K \subset \mathbb{R}^k$, and denote $x_+ = \max\{x, 0\}$. Then the formula

$$V(\xi) := \int_K (\xi - G(v))_+ H(v) \, dv, \quad \xi \in \mathbb{R},$$

defines a $C^1$ map on $\mathbb{R}$, and

$$V'(\xi) = \int_{G < \xi} H(v) \, dv.$$
Corollary 12. The function $\xi \mapsto \text{Vol}(S_{M,\xi})$ is $C^1$.

For a smaller range for $\xi$ we have the following explicit formula:

Lemma 13. Suppose that $\xi \leq Z_M$. The volume of $S_{M,\xi}$ only depends on $\xi$ and $T = \|M\|^2$:

$$\text{Vol}(S_{M,\xi}) = \int_0^{\frac{\pi}{4}} \tan^{-1}\left(\frac{\sqrt{\Delta} - \sqrt{\Delta - 4\xi^2 \cos^4 t}}{2\alpha \xi \cos^2 t}\right) dt + \frac{1}{2\xi \cos^2 t} \ln\left(1 - \frac{\sqrt{\Delta} - \sqrt{\Delta - 4\xi^2 \cos^4 t}}{2\alpha}\right) dt,$$

where $\Delta = T^2 - 4$ and $\alpha = \frac{1}{2}(T + \sqrt{T^2 - 4})$.

Proof. The two polar curves defined by (7-21) intersect for

$$|\sin(2\theta - \theta_M)| = \frac{2\xi}{\sqrt{T^2 - 4}} \cos^2 t,$$

that is, for $\theta_\pm = \theta_M/2 \pm \alpha$ with $\alpha = \alpha(\xi, t) \in (0, \pi/4)$ such that

$$\sin 2\alpha = \frac{2\xi}{\sqrt{T^2 - 4}} \cos^2 t.$$

Since $\sin \theta_M = 2Z/\sqrt{T^2 - 4}$, the assumption $\xi \leq Z$ ensures that $\alpha < \theta_M$. Thus $\theta_\pm \in [0, \pi/2)$, and the change of variables $\theta = \theta_M/2 + u$ yields

$$B_{M,\xi}(t) = \frac{1}{2} \int_{-\alpha}^{\alpha} \left(\frac{2 \cos^2 t}{\sqrt{T^2 - 4}} \cdot \frac{1}{U_T + \cos(2u)} - \frac{|\sin(2u)|}{\xi(U_T + \cos(2u))}\right) du.$$

The integrand is even and both integrals can be computed exactly, yielding the formula above.

In particular, Lemma 13 yields $\text{Vol}(S_{M,\xi}) \ll \xi/T^2$, providing an alternative proof for (7-17).

7.2. Exterior arcs. Referring to the notation of Section 5.2, we first replace the inequalities

$$p^2 + p'^2 + q^2 + q'^2 \leq Q^2$$

and

$$p^2 + q^2 + (Kp_\ell - p_{\ell-1})^2 + (Kq_\ell - q_{\ell-1})^2 \leq Q^2$$

in (5-7) by simpler ones. Using $p'q - pq' = 1$, we can replace $p$ by $p'/q'$ in the former, while $p_{\ell-1}$ can be replaced by $p_\ell q_{\ell-1}/q_\ell$ in the latter. As a result, these two inequalities can be substituted in (5-7) by

$$\left(1 + \frac{p'^2}{q'^2}\right) (q^2 + q'^2) \leq Q^2 (1 + O(Q^{-1})),

\left(1 + \frac{p^2}{q^2}\right) (q_\ell^2 + (Kq_\ell - q_{\ell-1})^2) \leq Q^2 (1 + O(Q^{-1})).$$

(7-23)
Since \( p_\ell/q_\ell = p'/q' + O(\ell/Q) \) and \( q_\ell^2 + (Kq_\ell - q_{\ell - 1})^2 \leq 2Q^2 \), the second inequality in (7-23) can be also written as
\[
\left(1 + \frac{p'^2}{q'^2}\right)(q_\ell^2 + (Kq_\ell - q_{\ell - 1})^2) \leq Q^2(1 + O(Q^{-1})),
\]
leading to
\[
R_Q^{(\cap)}(\xi) = \sum_{\ell \in [0, \xi]} \sum_{q < Q} J_{Q+O(Q^{1/2}),q',K,\ell}(\xi),
\]
where \( J_{Q,q',K,\ell}(\xi) \) denotes the number of integer lattice points \((p', q)\) such that
\[
0 \leq p' \leq q', \quad 0 \leq q \leq Q, \quad p'q \equiv 1 \pmod{q'}, \quad 0 < Kq_\ell - q_{\ell - 1} \leq Q,
\]
\[
\gamma_{\ell,K}\left(\frac{q}{Q}, \frac{q'}{Q}\right) \leq \xi, \quad p'^2 + q'^2 \leq \frac{Q^2q'^2}{\max\{q^2 + q'^2, q_\ell^2 + (Kq_\ell - q_{\ell - 1})^2\}}. \quad (7-24)
\]
Applying Lemma 7 to the set \( \Omega = \Omega_{q',K,\ell,\xi}^{(\cap)} \) of elements \((u, v)\) for which
\[
u \in [0, Q], \quad v \in [0, q'], \quad L_i\left(\frac{u}{Q}, \frac{q'}{Q}\right) > 0 \text{ for } i = 0, 1, \ldots, \ell,
\]
\[
0 < KL_\ell\left(\frac{u}{Q}, \frac{q'}{Q}\right) - L_{\ell-1}\left(\frac{u}{Q}, \frac{q'}{Q}\right) \leq 1, \quad \gamma_{\ell,K}\left(\frac{u}{Q}, \frac{q'}{Q}\right) \leq \xi,
\]
\[
v^2 + q'^2 \leq \frac{Q^2q'^2}{\max\{u^2 + q'^2, Q^2L_\ell^2\left(\frac{u}{Q}, \frac{q'}{Q}\right) + Q^2(KL_\ell\left(\frac{u}{Q}, \frac{q'}{Q}\right) - L_{\ell-1}\left(\frac{u}{Q}, \frac{q'}{Q}\right))^2\}},
\]
with \( A(\Omega) \leq Qq', \ell(\partial\Omega) \ll Q, \ell = (q')^{5/6}, \) we find
\[
J_{Q,q',K,\ell,\xi}^{(\cap)} = \frac{\varphi(q')}{q'} \cdot \frac{A(\Omega_{q',K,\ell,\xi}^{(\cap)})}{q'} + O_\varepsilon(Q(q')^{-1/6+\varepsilon}).
\]
This leads in turn to
\[
R_Q^{(\cap)}(\xi) = M_Q^{(\cap)}(\xi) + O_{\xi,\varepsilon}(Q^{11/6+\varepsilon}),
\]
where
\[
M_Q^{(\cap)}(\xi) = \sum_{\ell \in [0, \xi]} \sum_{K \in [1, \xi]} \frac{\varphi(q')}{q'} \cdot \frac{A(\Omega_{q',K,\ell,\xi}^{(\cap)})}{q'}.
\]
For fixed integers \( K \in [1, \xi], \ell \in [0, \xi] \), consider the subset \( T_{K,\ell,\xi} \) of \([0, 1]^3\) consisting of those \((x, y, z)\) in \([0, 1]^3\) such that
\[
0 < L_{\ell+1}(x, y) = KL_\ell(x, y) - L_{\ell-1}(x, y) \leq 1, \quad \gamma_{\ell,K}(x, y) \leq \xi,
\]
\[
\max\{x^2 + y^2, L_\ell^2(x, y) + L_{\ell+1}^2(x, y)\} \leq \frac{1}{1 + z^2}, \quad (7-25)
\]
with \( L_i \) and \( \gamma_{\ell,K} \) as in (5-5) and (5-6).
Möbius summation is now applied to \( h_2(q') = (1/q') A_h(\Omega_{q',K,\ell,\xi}) \). The quantity \( (1/Q) h_2(q') \) represents the area of the cross-section of the body \( T_{K,\ell,\xi} \) by the plane \( x = q'/Q \). This shows that \( h_2 \) is continuous and piecewise \( C^1 \) on \([0, Q]\), and furthermore the number of critical points of \( h_2 \) is bounded uniformly in \( \xi \) (and independently of \( Q \)). Hence the total variation of \( h_2 \) on \([0, Q]\) is \( \ll \xi \|h_2\|_\infty \leq Q \). Employing also the change of variables \( (q', u, v) = (Qx, Qy, Qxz) \), where \((x, y, z) \in [0, 1]^3\), we find

\[
M_{\Omega}(\xi) = \frac{1}{\zeta(2)} \sum_{k \in [0, \xi]} \left( \int_0^Q \frac{dq'}{q'} A_h(\Omega_{q',K,\ell,\xi}) + O(Q) \right)
\]

\[
= \frac{Q^2}{\zeta(2)} \sum_{k \in [0, \xi]} \text{Vol}(T_{K,\ell,\xi}) + O_\xi(Q),
\]

and so

\[
R_{\Omega}(\xi) = \frac{Q^2}{\zeta(2)} \sum_{k \in [0, \xi]} \text{Vol}(T_{K,\ell,\xi}) + O_\xi(Q^{11/6+\epsilon}). \tag{7-26}
\]

To show that \( \xi \mapsto \text{Vol}(T_{K,\ell,\xi}) \) is \( C^1 \) on \([1, \infty)\), we make the change of variables \((x, y, z) = (\cos \theta, \sin \theta, \tan t)\) to obtain

\[
\text{Vol}(T_{K,\ell,\xi}) = \int_0^{\pi/4} A_{K,\ell}(\xi, t) \frac{dt}{\cos^2 t}, \tag{7-27}
\]

where \( A_{K,\ell}(\xi, t) \) is the area of the region defined by the conditions in (1-3). Now notice that \( K_i(x, y) \leq \xi \) when \( 1 \leq i \leq \ell \), as a result of (omitting the arguments of the functions)

\[
K_i = \frac{L_i + L_{i-2}}{L_i} \leq \frac{1}{L_{i-2} L_{i-1}} + \frac{1}{L_{i-1} L_i} < \gamma_{\ell, K} \leq \xi.
\]

Similarly,

\[
K_1 = \frac{L_1 + L_0}{L_0} \leq \frac{L_{i-1}}{L_0} + \frac{1}{L_0 L_i} \leq \gamma_{\ell, K} \leq \xi.
\]

Thus the projection of \( T_{K,\ell,\xi} \) on the first two coordinates is included into the union of disjoint cylinders \( \mathcal{T}_k := \mathcal{T}_{k_1} \cap T^{-1}\mathcal{T}_{k_2} \cap \cdots \cap T^{-\ell+1}\mathcal{T}_{k_\ell} \) with \( \mathcal{T}_k = \{(x, y) : K_1(x, y) = k\} \) and \( k = (k_1, \ldots, k_\ell) \in [1, \xi]^{\ell} \). On each set \( \mathcal{T}_k \) all maps \( L_1, \ldots, L_\ell, L_{\ell+1} \) are linear, say \( L_i(x, y) = A_i x + B_i y \), with integers \( A_i, B_i \) depending only on \( k_1, \ldots, k_i \) for \( i \leq \ell \) and \( A_{\ell+1}, B_{\ell+1} \) depending only on \( k \) and \( K \). Therefore the function \( F_{K,\ell}(\theta) \) is continuous on each region \( \mathcal{T}_k \), and applying Lemma 11 we conclude that the function \( \xi \mapsto \text{Vol}(T_{K,\ell,\xi}) \) is \( C^1 \) on \([1, \infty)\), being a sum of \( [\xi]^\ell \) volumes, as functions \( \mapsto \) each of which is \( C^1 \) each of which is \( C^1 \) as a function of \( \xi \).
**Remark 14.** The region $T_{K, \ell, \xi}$ can be simplified further. For each integer $J \in [1, \xi)$, the map
\[
\Psi_J : (u, v) \mapsto (J L_\ell(u, v) - L_{\ell-1}(u, v), L_\ell(u, v))
\]
is an area preserving injection on $T$, since it is the composition of $T^\ell$ in (5-5) followed by the linear transformation $(u, v) \mapsto (Jv - u, v)$. Note that under this map (omitting the arguments $(u, v)$ of the functions below):
\[
L_1 \rightarrow \left[1 + J L_\ell - L_{\ell-1} \right] \frac{L_\ell}{L_1} - (J L_\ell - L_{\ell-1}) = L_{\ell - 1}
\]
(using $L_{\ell - 1} + L_\ell > 1$), and by induction it follows similarly that $L_i \rightarrow L_{\ell - i}$ for $0 \leq i \leq \ell$. Also we have that $\Psi_J(u, v) = (x, y) \in [0, 1]^2$ if and only if $x = J L_\ell - L_{\ell-1} \in [0, 1]$ and $J = [(1 + x)/y]$.

Let us decompose the region $T_{K, \ell, \xi}$ into a disjoint union of regions $T_{K, J; \ell, \xi}$, $1 \leq J < \xi$, obtained by adding the condition $[(1 + x)/y] = J$. By the discussion of the previous paragraph, the map $(\Psi_J, \text{Id}_z)$ is a volume preserving bijection taking $U_{K, J; \ell, \xi}$ onto $T_{K, J; \ell, \xi}$, where $U_{K, J; \ell, \xi}$ is the set of all $(x, y, z) \in [0, 1]^3$ such that
\[
x + y > 1, \quad J L_\ell - L_{\ell - 1} > 0, \quad KL_0 - L_1 > 0, \quad \gamma_{\ell, K, J} \leq \xi, \quad L_0^2 + (KL_0 - L_1)^2 \leq \frac{1}{1 + z^2}, \quad L_\ell^2 + (J L_\ell - L_{\ell - 1})^2 \leq \frac{1}{1 + z^2}.
\]
Here $L_i = L_i(x, y)$ and
\[
\gamma_{\ell, K, J}(x, y) = \frac{J L_\ell - L_{\ell - 1}}{L_\ell(L_0^2 + (J L_\ell - L_{\ell - 1})^2)} + \sum_{i=1}^{\ell} \frac{1}{L_i - L_{i-1}} + \frac{KL_0 - L_1}{L_0(L_0^2 + (KL_0 - L_1)^2)}.
\]

For $\alpha \geq 1$, the transformation $(\Psi_\alpha, \text{Id}_z)$ maps bijectively the part of $U_{K, J; \ell, \xi}$ for which $[(1 + L_{\ell - 1})/L_\ell] = \alpha$ onto the part of $U_{J, K; \ell, \xi}$ for which $[(1 + x)/y] = \alpha$. Therefore $\text{Vol}(U_{K, J; \ell, \xi}) = \text{Vol}(U_{J, K; \ell, \xi})$ and the sum of volumes appearing in (7-28) can be written more symmetrically:
\[
\sum_{K \in [1, \xi)} \text{Vol}(T_{K, \ell, \xi}) = \sum_{K, J \in [1, \xi)} \text{Vol}(U_{K, J; \ell, \xi}).
\]
As an example of using this formula, if $1 < \xi \leq 2$ and $\ell = 1$, we can only have $K = J = 1$ and the inequalities $J L_1 - L_0 > 0, KL_0 - L_1 > 0$ cannot be both satisfied, so $U_{1, 1; 1, \xi}$ is empty. Therefore the only contribution from the $T$ bodies in (7-28) comes from $T_{1, 0, \xi}$ if $\xi \in (1, 2]$.

We can now prove the main theorem on the pair correlation of the quantities $\tan(\theta_y/2)$.
Theorem 2. The pair correlation measure \( R^T_2 \) exists on \([0, \infty)\). It is given by the \( C^1 \) function
\[
R^T_2 (\frac{3}{8}\xi) = \frac{8}{3\xi(2)} \left( \sum_{M \in S} \text{Vol}(S_M, \xi) + \sum_{\ell \in [0, \xi)} \sum_{K \in [1, \xi)} \text{Vol}(T_{K, \ell, \xi}) \right),
\]
(7-28)
where the three-dimensional bodies \( S_{M, \xi} \) are defined by the conditions in (7-14) and the bodies \( T_{K, \ell, \xi} \) are defined by the conditions in (7-25).

Proof. By (7-19) and (7-26), with \( c_0 \in (\frac{1}{2}, 1) \) and \( G(\xi) \) denoting the sum of all volumes in (7-28), we infer that
\[
\mathcal{R}^\Phi_\Omega(\xi) = \frac{Q^2}{\xi(2)} G(\xi) + O_{\xi, \varepsilon}(Q^{(11+c_0)/6+\varepsilon}).
\]
(7-29)
It follows that the function \( G \) is \( C^1 \) on \([0, \infty)\) as a result of \( \xi \mapsto \text{Vol}(S_{M, \xi}) \) being \( C^1 \) on \([0, \infty)\), and of \( \xi \mapsto \text{Vol}(T_{K, \ell, \xi}) \) being \( C^1 \) on \([1, \infty)\). Corollary 4 and (7-29) now yield, for \( \beta \in (\frac{2}{3}, 1) \),
\[
\mathcal{R}^\Psi_\Omega(\xi) = \frac{Q^2}{\xi(2)} \left( G(\xi) + O(Q^{2-3\beta}) \right) + O_{\xi, \varepsilon}(Q^{1+\beta} \ln Q + Q^{(11+c_0)/6+\varepsilon}).
\]
Employing again the differentiability of \( G \) and \( G(0) = 0 \), and taking \( \beta = \frac{3}{4}, c_0 = \frac{1}{2} + \varepsilon \), this provides
\[
\mathcal{R}^\Psi_\Omega(\xi) = \frac{Q^2}{\xi(2)} G(\xi) + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon}).
\]
(7-30)
Equation (7-28) now follows from (7-30) and Corollary 8. \( \square \)

8. Pair correlation of \( \{\theta_r\} \)

8.1. Proof of Theorem 1. In this section we pass to the pair correlation of the angles \( \{\theta_r\} \), estimating
\[
\mathcal{R}^\theta_\Omega(\xi) : = \#\{ (\gamma, \gamma') \in \mathcal{R}^2_\Omega : 0 \leq Q^2(\theta_{\gamma'} - \theta_r) \leq \xi \}.
\]
Define the pair correlation kernel \( F(\xi, t) \) as follows:
\[
F(\xi, t) = \sum_{M \in S} B_M(\xi, t) + \sum_{\ell \in [0, \xi)} \sum_{K \in [1, \xi)} A_{K, \ell}(\xi, t),
\]
(8-1)
where \( B_M(\xi, t) \) and \( A_{K, \ell}(\xi, t) \) are the areas from (7-20) and (7-27), respectively, so that by (7-30) we have
\[
\mathcal{R}^\Psi_\Omega(\xi) = \frac{Q^2}{\xi(2)} \int_0^{\pi/4} F(\xi, t) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{(11+c_0)/6+\varepsilon}).
\]
Proposition 15. \( R^\theta_Q(\xi) = \frac{Q^2}{\zeta(2)} \int_0^{\pi/4} F\left( \frac{\xi}{2 \cos^2 t}, t \right) \frac{dt}{\cos^2 t} + O_{\xi,\varepsilon}(Q^{47/24+\varepsilon}). \)

Before giving the proof, note that Theorem 1 follows from the proposition as \( Q \to \infty \), taking into account the different normalization in the definitions of \( R^\theta_Q(\xi) \) and \( R^N_Q(\xi) \), and defining, in view of Proposition 15 and (8-1),

\[
B_M(\xi) := \int_0^{\xi/4} B_M\left( \frac{\xi}{2 \cos^2 t}, t \right) \frac{dt}{\cos^2 t}, \quad A_{K,\ell}(\xi) := \int_0^{\xi/4} A_{K,\ell}\left( \frac{\xi}{2 \cos^2 t}, t \right) \frac{dt}{\cos^2 t}.
\]

From the definitions of \( B_M(\xi, t) \), \( A_{K,\ell}(\xi, t) \) in the equations following (7-20), (7-27), it is clear that

\[
B_M\left( \frac{\xi}{2 \cos^2 t}, t \right) = B_M\left( \frac{\xi}{2}, 0 \right) \cos^2 t, \quad A_{K,0}\left( \frac{\xi}{2 \cos^2 t}, t \right) = A_{K,0}\left( \frac{\xi}{2}, 0 \right) \cos^2 t,
\]

hence one has

\[
B_M(\xi) = \frac{\pi}{4} B_M\left( \frac{\xi}{2}, 0 \right), \quad A_{K,0}(\xi) = \frac{\pi}{4} A_{K,0}\left( \frac{\xi}{2}, 0 \right), \quad (8-2)
\]

which together with (7-22) yields the formula for \( B_M(\xi) \) given in Theorem 1. Note that the range of summation in Theorem 1 restricts to \( K < \xi/2, \ell < \xi/2 \), compared with the range in (8-1). Indeed, from the description of \( A_{K,\ell}(\xi/2 \cos^2 t, t) \) following (7-27), we see that \( \ell < \gamma_{\ell,K} \leq \xi/2 \), while for \( K \) we have

\[
K < \frac{1}{L_{\ell-1}L_{\ell}} + \frac{KL_{\ell-1} - K\ell_{-1}}{L_{\ell}} < \gamma_{\ell,K} \leq \frac{\xi}{2},
\]

and similarly for \( \ell = 0 \).

Proof of Proposition 15. Consider \( I = [\alpha, \beta) \) with \( N = [Q^d] \), \( |I| = N^{-1} \sim Q^{-d} \), \( I^+ = [\alpha - Q^{-d'}, \beta + Q^{-d'}) \) and \( I^- = [\alpha + Q^{-d'}, \beta - Q^{-d'}] \), where

\[
0 < d = \frac{1}{24} < d' = \frac{1}{12} < 1.
\]

Partition the interval \([0, 1]\) into the union of \( N \) intervals \( I_j = [\alpha_j, \alpha_{j+1}) \), with \( |I_j| = N^{-1} \) as above. Associate the intervals \( I_j^+ \) to \( I_j \) as described above. Set

\[
R^\pm_Q := \{(\gamma, \gamma') \in \tilde{M}_Q^\pm : \gamma \neq \gamma'\},
\]

\[
R^\theta_{I,Q}(\xi) := \#\{(\gamma, \gamma') \in \tilde{M}_Q^\pm : 0 \leq Q^2(\theta_{\gamma'} - \theta_\gamma) \leq \xi, \Psi(\gamma), \Psi(\gamma') \in I\},
\]

\[
R^\Phi_{I,Q}(\xi) := \#\{(\gamma, \gamma') \in \tilde{M}_Q^\pm : 0 \leq Q^2(\Phi(\gamma') - \Phi(\gamma)) \leq \xi, \gamma_-, \gamma_+ \in I\},
\]

\[
R^{\Phi,b}_{I,Q}(\xi) := \#\{(\gamma, \gamma') \in \tilde{M}_Q^\pm : 0 \leq Q^2(\Phi(\gamma') - \Phi(\gamma)) \leq \xi, \gamma_-, \gamma_+ \in I\}.
\]

1030 Florin P. Boca, Vicentiu Pasol, Alexandru A. Popa and Alexandru Zaharescu
Expressing $\theta_{\gamma'} - \theta_{\gamma}$ and $\Psi(\gamma') - \Psi(\gamma)$ via the mean value theorem, we find

$$R^\theta_{I,Q}(\frac{1}{2}(1 + \alpha^2)\xi) \leq R^\theta_{I,Q}(\xi) \leq R^\theta_{I,Q}(\frac{1}{2}(1 + \beta^2)\xi).$$

(8-3)

**Lemma 16.** The following estimates hold:

(i) \[ \sum_{j=1}^{N} R^\theta_{I_j,Q}(\xi) \leq R^\theta_{Q}(\xi) = \sum_{j=1}^{N} R^\theta_{I_j,Q}(\xi) \leq \sum_{j=1}^{N} R^\theta_{I^+_j,Q}(\xi) + O(Q^{15/8} \ln^2 Q). \]

(ii) \[ R^\psi_{I,Q}(\xi) = R^\psi_{I,Q}(\xi) + O(Q^{1+d'} \ln^2 Q). \]

**Proof.** The first inequality in (i) is trivial. For the second one, note first that the total number of pairs $(\gamma, \gamma')$ with $0 \leq \theta_{\gamma'} - \theta_{\gamma} < Q^{-2}$ and $\gamma' < Q^{d'}$, with $\gamma_+ = p/q$ and $\gamma_+ = p'/q'$, is $\ll Q^{d'}(Q^d \ln Q)(Q \ln Q)$. For $\gamma$ with $q < Q^{-d'}$, use $\Psi(\gamma') - \beta \leq \Psi(\gamma') - \Psi(\gamma) \leq 1/qq' < Q^{-d'}$, so $\Psi(\gamma') \in I^+_j$. The proof of (ii) is analogous.

Lemma 16 and (8-3) yield

$$\sum_{j=1}^{N} R^\psi_{I_j,Q}(\frac{1}{2}(1 + \alpha^2)\xi) \leq R^\psi_{Q}(\xi) \leq \sum_{j=1}^{N} R^\psi_{I^+_j,Q}(\frac{1}{2}(1 + \alpha^2)\xi) + O_\varepsilon(Q^{15/8+\varepsilon}).$$

To estimate $R^\Phi_{I,Q}(\xi)$ we repeat the previous arguments for a short interval $I$ as above. Adding everywhere the condition $\gamma_-, \gamma_+ \in I$, we modify $R^\Phi_{I,Q}$ by $R^\Phi_{I,Q}$ and $R^\theta_{I,Q}$ by $R^\theta_{I,Q}$ in Lemma 5, $R^\psi_{I,Q}$ by $R^\psi_{I,Q}$ and $R^\psi_{Q}$ by $R^\psi_{Q}$ in Lemma 6. The additional condition $p/q, p'/q' \in I$ is inserted in (7-2). The condition $0 < p' < q'$ is replaced by $q'\alpha < p' < q'\beta$ in (7-4) and (7-24), and $0 < p < q$ is replaced by $q\alpha < p < q\beta$ in (7-4). The condition $v \in [0, q']$ is replaced by $v \in [q'\alpha, q'\beta]$ in the definition of $\Omega_{M,q',\xi}$ and $\Omega_{q',\varepsilon,K,\xi}$. The bodies $S_{I,M,\xi}$ and $T_{K,\varepsilon,\xi}$ are substituted, respectively, by $S_{I,M,\xi}$ and $T_{I,K,\varepsilon,\xi}$ after replacing the condition $z \in [0, 1]$ in their definitions by $z \in [\alpha, \beta]$. The analogs of (7-20) and (7-27) hold:

$$\text{Vol}(S_{I,M,\xi}) = \int_I B_M(\xi, t) \frac{dt}{\cos^2 t}, \quad \text{Vol}(T_{I,K,\xi,\xi}) = \int_I A_{K,\varepsilon}(\xi, t) \frac{dt}{\cos^2 t}. \quad (8-4)$$

The approach from Section 7 under the changes specified in the previous paragraph leads to

$$R^\Phi_{I,Q}(\xi) = R^\Phi_{I,Q}(\xi) + R^\psi_{I,Q}(\xi) = \frac{Q^2}{\zeta(2)} \int_{\tan^{-1} I} F(\xi, t) \frac{dt}{\cos^2 t} + O_{\xi,\varepsilon}(Q^{23/12+\varepsilon}),$$

(8-5)

with the pair correlation kernel $F(\xi, t)$ defined by (8-1). We also have

$$R^\Phi_{I^+,Q}(\xi) = R^\Phi_{I,Q}(\xi) + O_{\xi,\varepsilon}(Q^{23/12+\varepsilon} + Q^{2-d'}).$$

(8-6)
The analogs of Lemmas 5 and 6 yield, upon (8-5) and (8-6),

$$R_{I, Q}(\xi) = \frac{Q^2}{\xi(2)} \int_{\tan^{-1} I} F(\xi + O(Q^{-1/3}), t) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon}) = R_{I^+, Q}(\xi).$$

The analog of Corollary 4 and (8-7) yield

$$R_{I, Q}(\xi) = \frac{Q^2}{\xi(2)} \int_{\tan^{-1} I} F(\xi + O(Q^{-1/4}), t) + O(\xi) + O_{\xi, \varepsilon}(Q^{7/4+\varepsilon})$$

$$= \frac{Q^2}{\xi(2)} \int_{\tan^{-1} I} \left( F(\xi + O(Q^{-1/4}), t) + F(Q^{-1/4}, t) \right) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon})$$

$$= R_{I^+, Q}(\xi).$$

As shown in Section 7, the function $F$ is $C^1$ in $\xi$, thus (8-8) gives actually

$$\frac{Q^2}{\xi(2)} \int_{\tan^{-1} I} F(\xi, t) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon}) = R_{I^+, Q}(\xi).$$

Lemma 16(i), (8-9), and the fact that $F \in C^1[0, \infty)$ yield

$$\frac{Q^2}{\xi(2)} \int_{\tan^{-1} I} F(\xi) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon} + Q^{2-d'}) = R_{I^+, Q}(\xi).$$

Let also $\omega_j = \tan^{-1} \alpha_j$. From (8-10) and (8-3) we further infer

$$\frac{Q^2}{\xi(2)} \int_{\omega_j}^{\omega_{j+1}} F\left(\frac{1}{2}(1 + \alpha_j^2)\xi, t\right) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon} + Q^{2-d'})$$

$$\leq R_{I^+, Q}^0(\xi) \leq R_{I^+, Q}(\xi)$$

$$\leq \frac{Q^2}{\xi(2)} \int_{\omega_j}^{\omega_{j+1}} F\left(\frac{1}{2}(1 + \alpha_{j+1}^2)\xi, t\right) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon} + Q^{2-d'}).$$

Employing also

$$\int_{\omega_j}^{\omega_{j+1}} F\left(\frac{1}{2}(1 + \alpha_j^2)\xi, t\right) \frac{dt}{\cos^2 t} = \int_{\omega_j}^{\omega_{j+1}} \left( F\left(\frac{1}{2}(1 + \tan^2 t)\xi, t\right) + O(\omega_{j+1} - \omega_j) \right) \frac{dt}{\cos^2 t}$$

and $(\omega_{j+1} - \omega_j)^2 \leq Q^{-2d}$, we find that

$$R_{I^+, Q}^0(\xi) = \frac{Q^2}{\xi(2)} \int_{\omega_j}^{\omega_{j+1}} F\left(\frac{1}{2}(1 + \tan^2 t)\xi, t\right) \frac{dt}{\cos^2 t} + O_{\xi, \varepsilon}(Q^{23/12+\varepsilon}) = R_{I^+, Q}^0(\xi).$$

This, together with Lemma 16(i), yields the equality from Proposition 15. 

\[\square\]
8.2. Explicit formula for $g_2^M$. Next we compute the derivatives $B'_M(\xi)$, thus proving Corollary 1. We also obtain the explicit formula (8-11) for $g_2^M$ on a larger range than in Corollary 1, after computing the derivative $A'_{K,0}(\xi)$.

**Lemma 17.** For $M \in \mathcal{G}$, let $T = T_M$, $Z = Z_M$ as in (3-1). The derivative $B'_M(\xi)$ is given by

$$
\begin{align*}
\frac{\pi}{4\xi^2} \ln \left( \frac{T + \sqrt{T^2 - 4}}{T + \sqrt{T^2 - 4 - \xi^2}} \right) & \quad \text{if } \xi \leq 2Z, \\
\frac{\pi}{8\xi^2} \ln \left( \frac{(T + \sqrt{T^2 - 4})(T - \sqrt{T^2 - 4})}{(4 + 4Z^2)(T + \sqrt{T^2 - 4 - \xi^2})} \right) & \quad \text{if } 2Z \leq \xi \leq \sqrt{T^2 - 4}, \\
\frac{\pi}{8\xi^2} \ln \left( \frac{(T + \sqrt{T^2 - 4})^2}{4 + 4Z^2} \right) & \quad \text{if } \xi \geq \sqrt{T^2 - 4}.
\end{align*}
$$

**Proof.** Using (8-2), we proceed as in the proof of Lemma 13:

$$
B_M(\xi) = \frac{\pi}{4\xi} \int_0^{\pi/2} \left( \frac{\xi \sqrt{T^2 - 4}}{U_T + \cos(2\theta - \theta_M)} - \frac{|\sin(2\theta - \theta_M)|}{U_T + \cos(2\theta - \theta_M)} \right) d\theta,
$$

where $U_T = T / \sqrt{T^2 - 4}$, and $\theta_M \in (0, \pi/2)$ has $\sin \theta_M = 2Z / \sqrt{T^2 - 4}$. Applying Lemma 11, we obtain

$$
B'_M(\xi) = \frac{\pi}{4\xi^2} \int_I \frac{|\sin(2\theta - \theta_M)|}{U_T + \cos(2\theta - \theta_M)} d\theta,
$$

with $I = \{ \theta \in (0, \pi/2) : |\sin(2\theta - \theta_M)| < \xi / \sqrt{T^2 - 4} \}$. Clearly $I = (0, \pi/2)$ when $\xi > \sqrt{T^2 - 4}$, and if $\xi \leq \sqrt{T^2 - 4}$, let $\alpha = \alpha(\xi) \in (0, \pi/4)$ be such that $\sin 2\alpha = \xi / \sqrt{T^2 - 4}$. Then

$$
\xi \leq 2Z \iff \alpha \leq \theta_M/2 \iff I = [\theta_M/2 - \alpha, \theta_M/2 + \alpha], \\
2Z \leq \xi \leq \sqrt{T^2 - 4} \iff \alpha \in [\theta_M/2, \pi/4] \iff I = [0, \theta_M/2 + \alpha] \cup [\pi/2 + \theta_M/2 - \alpha, \pi/2],
$$

and the integral is easy to compute. For $M = \left( \begin{array}{c} 1 \\ 0 \end{array} \right)$ and $\xi = 3$, the region with area $B_M(\xi/2, 0)$ is the one hatched vertically in Figure 6. \hfill $\square$

A similar computation using (8-2) shows that $A'_{K,0}(\xi)$ is given by

$$
\frac{\pi}{4\xi^2} \begin{cases} 
0 & \text{if } \xi \leq 2K, \\
\ln(1 + K^2) + \ln \left( \frac{(1 + x_1^2)(1 + (x_2 - K)^2)}{(1 + x_2^2)(1 + (x_1 - K)^2)} \right) & \text{if } \xi \in [2K, K\sqrt{K^2 + 4}], \\
\ln(1 + K^2) & \text{if } \xi \geq K\sqrt{K^2 + 4},
\end{cases}
$$

where $x_2 > x_1$ are the roots of

$$
x^2(\xi + 2K) - 2xK(\xi + K) + \xi(K^2 + 1) - 2K = 0.
$$
By the last paragraph in Remark 14, the body $T_{1,1,\xi}$ is empty, so $A_{1,1}(\xi) = 0$, and we have an explicit formula on a larger range than in the introduction:

$$g_2^\xi \left( \frac{3}{4\pi} \xi \right) = \frac{32\pi}{9\zeta(2)} \left( \sum_{M \in \mathfrak{S}} B'_M(\xi) + A'_{1,0}(\xi) \right), \quad 0 < \xi \leq 4. \quad (8-11)$$

We can now explain the presence of the spikes in the graph of $g_2^\xi$ in Figure 1. The function $B'_M(\xi)$ is not differentiable at $\xi = 2F$ and $\sqrt{T^2 - 4}$, while the function $A'_{K,0}(\xi)$ is not differentiable at $\xi = 2K$ and $\sqrt{(K^2 + 2)^2 - 4}$. At the point $\xi = \sqrt{5}$, two of the functions $B'_M(\xi)$, as well as $A'_{1,0}(\xi)$, have infinite slopes on the left, which gives the spike on the graph of $g_2^\xi(x)$ at $x = (3/4\pi)\sqrt{5}$.
