Abstract

In the early 1980's Mike Freedman showed that all knots with trivial Alexander polynomial are topologically slice (with fundamental group \mathbb{Z}). This paper contains the first new examples of topologically slice knots. In fact, we give a sufficient *homological* condition under which a knot is slice with fundamental group $\mathbb{Z} \times \mathbb{Z}[1/2]$. These two fundamental groups are known to be the only *solvable ribbon* groups. Our homological condition implies that the Alexander polynomial equals $(t - 2)(t^{-1} - 2)$ but also contains information about the metabelian cover of the knot complement (since there are many non-slice knots with this Alexander polynomial).

1 Introduction

A *knot* is an embedding $S^1 \hookrightarrow S^3$. We work in the topological category and assume that every embedding is *locally flat*. Note that a smooth embedding is locally flat and that we prefer to *add* the adjective “smooth” to emphasize this *stronger* condition on the embedding, except in our title. Two knots are called *concordant* if there exists an embedding $S^1 \times [0, 1] \hookrightarrow S^3 \times [0, 1]$ which restricts to the given knots at both ends. The concordance classes form an abelian group under connected sum, the knot concordance group \mathcal{C} . A knot is called *slice* if it is concordant to the unknot or, equivalently, if it bounds an embedding of disks $D^2 \hookrightarrow D^4$. Predating the 4–dimensional revolution in the early 80’s, Casson and Gordon showed that the epimorphism from \mathcal{C} onto its high dimension analogue has a nontrivial kernel [2]. There has been much recent progress in understanding how complicated \mathcal{C} really is. In [5], [6] an infinite sequence of new invariants was found using non-commutative Blanchfield forms and their von Neumann signatures. On the other hand, many knots are known to be slice, for example the knots in Figure 1.1, where the band can be tied into an arbitrary knot C . In fact, there is a large class of slice knots given as the

Figure 1.1: A family of ribbon knots

boundary of *ribbons* in S^3 . These knots are called *ribbon knots*, where a *ribbon* is a smooth immersion $D^2 \looparrowright S^3$ such that all singularities are of the type as in Figure 1.2: They consist of arcs of self–intersection that lie completely in the interior of one of the two sheets involved. Such singularities can be resolved in D^4 by pushing an open disk around each singular arc slightly away from ∂D^4 . Thus a ribbon leads to a smooth slice disk in D^4 , the so called *ribbon disk*. It is a fascinating open problem whether every smoothly slice knot is ribbon. One distinctive feature of a ribbon knot is that the inclusion map induces an *epimorphism* of the knot group onto the *ribbon group*, the fundamental group of the complement in D^4 of the ribbon disk. There is a simple criterion for a given group to be ribbon in terms of certain presentations, see Theorem 2.1. For

general slice complements the inclusion map does *not* induce an epimorphism, and slice disks with the ontteness property are called *homotopically ribbon*, or *h-ribbon* for short.

Figure 1.2: Local singularity of a ribbon

In the topological category, Freedman proved that any knot with trivial Alexander polynomial is slice [10], see also [13] for a more direct construction. Using gauge theory, Gompf showed that some of these knots are *not* smoothly slice [14]. The easiest such knot is probably the Whitehead double of the trefoil knot, already exhibiting the subtle difference between smooth and topological 4-manifolds. In an amazing turn of events, Rasmussen very recently gave the first purely combinatorial proof for the fact that this knot is not smoothly slice. He constructed a concordance invariant from Khovanov homology [28] with beautiful properties. In particular, the arguments of [22] for showing that (iterated) Whitehead doubles of the trefoil are not smoothly slice can be adapted to this setting from the concordance invariant of Ozsváth and Szabó [23]. Livingston uses the following argument, going back to at least Rudolph: One can exhibit some Whitehead doubles as separating curves on minimal Seifert surfaces of certain torus knots. Since the Rasmussen and Ozsváth–Szabó invariants detect the minimal genus of torus knots, it follows that such separating curves cannot be smoothly slice.

In this note we provide the first new class of slice knots since Freedman’s construction, using his theorem [9] that solvable groups are good (for topological surgery). Our main result is the following theorem. Let

$$SR := \langle a, c \mid aca^{-1} = c^2 \rangle \cong \mathbb{Z} \rtimes \mathbb{Z}[1/2].$$

Here the generator a of \mathbb{Z} acts on the normal subgroup $\mathbb{Z}[1/2]$ via multiplication by 2. It is known, cf Lemma 2.2, that SR and \mathbb{Z} are the only *solvable ribbon* groups, hence the name. In geometric group theory, this group is also known as the *Baumslag–Solitar group* $B(1, 2)$.

Theorem 1.3 *Let K be a knot and denote by M_K the 0-surgery on K . If there is an epimorphism $\pi_1(M_K) \twoheadrightarrow G$, $G = SR$ or \mathbb{Z} , such that*

$$\mathrm{Ext}_{\mathbb{Z}[G]}^1(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0 \quad (\mathrm{Ext})$$

then K is (topologically) slice. In fact, K is h -ribbon with group G if and only if this Ext-condition holds for some epimorphism $\pi_1(M_K) \twoheadrightarrow G$.

The case $G = \mathbb{Z}$ is actually just a reformulation of Freedman's theorem because the condition (Ext) is then equivalent to $\Delta_K(t) = 1$. For $G = SR$, we shall show in Corollary 3.4 that this condition implies

$$\Delta_K(t) = (t - 2)(t^{-1} - 2).$$

There are well known knots with this Alexander polynomial that are not slice (cf Section 7) so the h -ribbon question with group SR is more subtle than for \mathbb{Z} . Our result complements work of Tim Cochran and Taehee Kim [7]. They show that if the degree of the Alexander polynomial is greater than two, then the homology of solvable covers can not determine whether a given knot is slice or not.

Remark We will show in Lemma 5.1 that the somewhat awkward (Ext) condition can be replaced by the condition that a non-commutative Blanchfield pairing

$$Bl: H_1(M_K; \mathbb{Z}[G]) \times H_1(M_K; \mathbb{Z}[G]) \longrightarrow Q(G)/\mathbb{Z}[G]$$

vanishes, where $Q(G)$ denotes the Ore localization of $\mathbb{Z}[G]$.

It is surprisingly easy to construct many knots that satisfy all conditions of our Theorem 1.3. For example, all knots in Figure 1.1 do. The easiest one is the knot 6_1 , which is isotopic to the case where the band C is the unknot. However, all knots in Figure 1.1 are obviously ribbon and hence we need to work harder to get new h -ribbon knots. One trick is the following satellite construction that can be considered as an analogue of Whitehead doubling (a nice way to obtain knots with trivial Alexander polynomial). We give a much more general result in Section 6.

Theorem 1.4 *Start with the knot 6_1 , drawn in a solid torus as on the right hand side of Figure 1.5. Tie an arbitrary knot into that solid torus to obtain a satellite K of 6_1 . Then K satisfies the assumptions of Theorem 1.3 and is therefore h -ribbon.*

On the left hand side of Figure 1.5 we picked an axis A which is unknotted in S^3 (so that the complement of A will be a solid torus) and which punctures all ribbon disks that we could see. Then we redrew the picture in a way that A becomes the meridian to the visible solid torus. We conjecture that Theorem 1.4

Figure 1.5: The knot 6_1 in the solid torus $S^3 \setminus A$

gives new examples of knots which are h -ribbon but not smoothly slice. The simplest candidate is the satellite knot of the trefoil knot. It has a knot diagram with 93 crossings and we are unable to compute Rasmussen’s invariant [28], the complexity of which is exponential in the number of crossings. For the general ribbon case we propose the following generalization of Theorem 1.3.

Conjecture 1.6 *Let G be a ribbon group for which topological surgery works. A knot K is h -ribbon with group G if and only if there exists an epimorphism $\varphi: \pi_1(M_K) \rightarrow G$ such that the condition (Ext) from Theorem 1.3 holds.*

Note that the converse of this conjecture is not completely straight forward either. We use a Blanchfield form to prove the converse for the groups $G = SR$ and \mathbb{Z} .

Question 1.7 *Are the fundamental groups of complements of h -ribbons ribbon groups?*

The phrase “surgery works for G ” means here that the (reduced) surgery sequence

$$S_{TOP}^h(X, M) \longrightarrow \tilde{N}_{TOP}(X, M) \longrightarrow \tilde{L}_4^h(\mathbb{Z}[G]) \tag{S}$$

is exact for all Poincaré pairs (X, M) with $\pi_1(X) = G$, see [10, chapter 11.3] for more information. If $G = SR$ or \mathbb{Z} then this sequence is exact by Freedman’s disk embedding theorem (cf [9] and [11]) for solvable groups. The general case is still open and since most other ribbon groups contain free groups we need a very strong form of this result. It is logically possible that topological surgery works for a given fundamental group but the disk embedding theorem (and hence the s -cobordism theorem) fail for this group.

The “if”-direction of Conjecture 1.6 would follow from the following purely homological conjecture. We say that (M_K, φ) satisfies the *Poincaré duality*

condition if the induced inclusion $M_K \hookrightarrow K(G, 1)$ is a finite 4–dimensional Poincaré pair.

Conjecture 1.8 *Let K be a knot with an epimorphism $\pi_1(M_K) \twoheadrightarrow G$ onto a ribbon group such that the condition (Ext) from Theorem 1.3 holds. Then (M_K, φ) satisfies the Poincaré duality condition. Moreover, $\tilde{L}_4^h(\mathbb{Z}[G]) = 0$.*

We give supporting evidence for this algebraic conjecture at the end of Section 2. For $G = \mathbb{Z}$ it is true out of easy reasons and in Lemmas 3.3, 4.1 and Lemma 4.4 we prove that the conjecture is true for $G = SR$. The main reason why this works is the fact that the group ring $\mathbb{Z}[SR]$ is an Ore-domain and hence has an ordinary (skew) quotient field, see Section 4. We use various lemmas and ideas from [5]. The first statement of Theorem 1.3 is then a consequence of the following general result.

Theorem 1.9 *Let G be a finitely presented group for which topological surgery works and with $H_1(G) \cong \mathbb{Z}$, $H_2(G) = 0$ and $\tilde{L}_4^h(\mathbb{Z}[G]) = 0$. A knot K is h –ribbon with group G if there is an epimorphism $\varphi: \pi_1(M_K) \twoheadrightarrow G$ such that (M_K, φ) satisfies the Poincaré duality condition. In particular, Conjecture 1.6 follows from Conjecture 1.8.*

Theorem 1.9 comes from the fact that given a Poincaré pair, one can attempt to use classical surgery theory to find a 4–manifold W of type $K(G, 1)$. We show that in the situation above, this approach successfully produces a h –ribbon complement that is a $K(G, 1)$.

The paper is organized as follows. In Section 2 we recall several known facts about ribbon groups. In Section 3 we explain how surgery can be used to find h –ribbons. We accumulate several restrictions on the group G , and in Section 4 we show that the group SR satisfies all of them. In Section 5 we will show that for our groups the (Ext)–condition can be replaced by a vanishing condition on a non–commutative Blanchfield pairing. In Section 6 we recall the satellite construction which we use to give examples of topologically slice knots in Section 7.

Acknowledgments We thank Chuck Livingston and the referee for their valuable comments on the first version of this paper. We also wish to thank Jerry Levine and Andrew Ranicki for helpful discussions regarding certain technical aspects in this paper.

2 Ribbon disk complements

Definition A group G is called *ribbon* if there exists a ribbon disk $D \hookrightarrow D^4$, as explained in the introduction, with $\pi_1(D^4 \setminus D) \cong G$.

The deficiency of a presentation of a group is the number of generators minus the number of relations. The deficiency $\text{def}(G)$ of a finitely presented group G is the maximum of the deficiencies of all presentations. The following theorem is well-known and uses the fact that any ribbon in 3-space can be obtained as follows: Start with an s -component unlink and add $(s - 1)$ bands to produce a knot, where the bands can be arbitrarily twisted and linked. In particular, the bands may hit the disks bounding the unlink which introduces our ribbon singularities. This description actually gives an embedded disk $D \hookrightarrow D^4$ with a Morse function $D^4 \rightarrow [0, 1]$ which has s minima and $(s - 1)$ saddles when restricted to D . This implies that the complement $N_D := D^4 \setminus \nu D$, νD an open tubular neighborhood of D , has a handle decomposition with one 0-handle, s 1-handles and $(s - 1)$ 2-handles, giving the desired group presentation.

Theorem 2.1 A group G is ribbon if and only if $H_1(G) = \mathbb{Z}$ and G has a Wirtinger presentation of deficiency one, ie, G has a presentation of the form

$$G = \langle g_1, \dots, g_s \mid r_1, \dots, r_{s-1} \rangle,$$

where $r_i = g_{h_i} g_{l_i}^{\epsilon_i} g_{k_i}^{-1} g_{l_i}^{-\epsilon_i}$ for some $h_i, k_i, l_i \in \{1, \dots, s\}$ and $\epsilon_i \in \{-1, 1\}$.

Using the above theorem and the Wirtinger presentation, one sees that knot groups are ribbon. As pointed out by John Stallings, a direct geometric way to see the corresponding ribbon disk is as follows. Represent the knot by an arc ending in a plane $P \subset \mathbb{R}^3$. A rotation by 180 degrees in \mathbb{R}^4 , with fixed plane P , sweeps out a disk in D^4 which has the same local minima and saddles as the original knotted arc (when projected orthogonally to the fixed plane) and there are no maxima. Applying this construction to a knot K , one obtains a ribbon disk with fundamental group $\pi_1(S^3 \setminus K)$ and boundary $K \# (-K)$. We recover by this argument the reason why the mirror image $-K$ is the inverse of K in the concordance group.

Lemma 2.2 The only solvable ribbon groups are \mathbb{Z} and $SR = \mathbb{Z} \times \mathbb{Z}[1/2]$.

Proof Wilson [32] shows that every solvable group of deficiency one is isomorphic to $G_k := \mathbb{Z} \times \mathbb{Z}[t, t^{-1}]/(tk - 1)$ for some k . A direct computation shows that $G_k/[G_k, G_k] = \mathbb{Z}$ if and only if $k = 0, 2$. These are exactly the two groups in the statement. Below we show that SR is indeed a ribbon group. \square

We now show that SR does in fact appear as the fundamental group of a ribbon disk complement. Let D be the ribbon disk given by Figure 1.1. The corresponding ribbon disk complement N_D is given by the handle diagram of Figure 2.3, with two (dotted) 1–handles and one 2–handle. This is the case $s = 2$ in the discussion above Theorem 2.1, see also [15, p. 213]. Note that with

Figure 2.3: Handle decomposition of N_D , with generators a, b for $\pi_1(N_D)$.

$c := ab^{-1}$ one gets

$$\pi_1(D^4 \setminus D) = \langle a, b \mid a^{-1}ba^{-1}bab^{-1} \rangle = \langle a, c \mid aca^{-1} = c^2 \rangle = SR.$$

which is in fact independent of the knot C that was tied into the band in Figure 1.1.

Remark Writing $R(C)$ for the above ribbon knot, then $R(C)$ is a *satellite knot* with companion C and orbit $R := R(\text{trivial knot})$. The knot R is the knot 6_1 of the standard knot table and we shall construct many more examples in this manner in Section 6.

Remark Since any ribbon group $\pi_1(N_D)$ has a presentation of deficiency $\text{rank}(H_1(N_D)) = 1$ it is in particular an E–group (cf [30, p. 324]), hence $\pi_1(N_D)^{(1)}$ is an E–group (cf [30, p. 302]). It follows from a result of Roushon [29, Corollary 4.6] in the case that $\text{rank}_{\mathbb{Z}}(\pi_1(N_D)^{(1)}/\pi_1(N_D)^{(2)}) \geq 2$ that the derived series of $\pi_1(N_D)$ never stabilizes, ie, $\pi_1(N_D)^{(i)} \neq \pi_1(N_D)^{(i+1)}$ for all $i \in \mathbb{N}$ (cf also [3]). This means that with few exceptions ribbon groups are neither solvable nor does their derived series stabilize.

The ribbon group conjecture

Alexander duality implies that ribbon groups satisfy $H_1(G) \cong \mathbb{Z}$ and $H_2(G) = 0$. We say that a group G is *aspherical* if $K(G, 1)$ is a 2–complex. For a ribbon

group $G = \pi_1(D^4 \setminus D)$ this is the case if $\pi_2(D^4 \setminus D) = 0$. It is conjectured that ribbon groups are aspherical. Note that this is in turn a special case of the Whitehead conjecture. This conjecture is known to be true for all knot groups since knot complements are aspherical by the sphere theorem. It is also known for all locally indicable ribbon groups (cf [16]), which in particular includes all ribbon groups with $G^{(\alpha)} = \{e\}$ for some ordinal α (cf also [30]). For some more examples cf [17]. In particular, we conjecture that a ribbon group G has the property that

$$H_3(G) = 0 \text{ and } \text{Ext}_{\mathbb{Z}[G]}^i(\mathbb{Z}, \mathbb{Z}[G]) = 0 \text{ for } i > 2.$$

This conjecture clearly holds for aspherical ribbon groups. Furthermore we conjecture that for a ribbon group G and an epimorphism $\varphi: \pi_1 M_K \twoheadrightarrow G$, we always have

$$\text{Hom}_{\mathbb{Z}[G]}(H_i(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0 \text{ for } i = 1, 2.$$

The relevance of these properties comes from Lemma 3.3 and Theorem 1.9. We will prove all these properties for $G = SR$ in Lemma 4.1.

3 Proof of the Main Theorem 1.3

Let K be a knot in S^3 and denote by M_K the result of zero framed surgery along K . The following is a well known slice criterion, see eg, [5]. For the “only if” direction one takes W to be the complement in D^4 of a (thickened up) slice disk. For the “if” direction one uses Freedman’s solution of the topological Poincaré conjecture in dimension 4, in order to recognize as D^4 the 4–manifold W union a 2–handle along a meridian for K in M_K .

Proposition 3.1 *A knot K is slice if and only if M_K^3 bounds a 4–manifold W^4 with*

- (1) $\pi_1(W)$ is normally generated by the image of a meridian for K ,
- (2) $H_1(W) \cong \mathbb{Z}$,
- (3) $H_2(W) = 0$,

Furthermore, K is h –ribbon with group $\pi_1(W)$ if and only if (1) is replaced by (1-h) $\pi_1(M_K) \rightarrow \pi_1(W)$ is surjective.

Note that the first two conditions can always be satisfied, even with $\pi_1(W) \cong \mathbb{Z}$. However, to satisfy condition (3) as well, it is often necessary to make the fundamental group of W more complicated. In fact, if (1)–(3) are satisfied for $\pi_1(W) \cong \mathbb{Z}$ then K has vanishing Alexander polynomial. Thus the main problem is to find a candidate for the fundamental group of W .

3.1 Outline of the construction of W

To prove Theorem 1.3, we take our candidate for the fundamental group to be $G = SR$ or \mathbb{Z} . By assumption we have given an epimorphism $\varphi: \pi_1 M_K \rightarrow G$ and we would like to find a $K(G, 1)$ -manifold W with boundary M_K such that the inclusion induces φ . Since any ribbon group satisfies $H_1(G) = \mathbb{Z}$ and $H_2(G) = 0$, such a manifold W would fulfill the conditions (1-h), (2) and (3) above. This means that we are in a classical surgery situation and we can follow the steps taken by many before us. Below, the steps are labelled by the section numbers where they will be worked out.

- (3.2) First we seek conditions such that $(K(G, 1), M_K)$ is a Poincaré pair. It turns out that exactly condition (Ext) from Theorem 1.3 arises.
- (3.3) Secondly, we check that the Spivak normal bundle of this Poincaré pair has a linear reduction, ie, that there is a degree 1 normal map from a (smooth) manifold pair $(N, M_K) \rightarrow (K(G, 1), M_K)$. In fact, we shall see that there is a *unique* normal cobordism class of such maps if we require, as we shall, that the signature of N is zero.
- (3.4) This normal map has surgery obstruction in the reduced L-group $\tilde{L}_4^h(\mathbb{Z}[G])$. Since $\pi_2 K(G, 1) = 0$ this quadratic form is nothing but the intersection form on $\pi_2 N$. We will verify in Lemma 4.4 that our L-group vanishes and hence the intersection form on $\pi_2 N$ is (stably) hyperbolic.
- (3.5) Finally, since by assumption the surgery sequence (\mathcal{S}) for our fundamental groups is exact (in the topological category), one gets a topological manifold W together with a homotopy equivalence $(W, M_K) \rightarrow (K(G, 1), M_K)$. Hence we found our h-ribbon by Proposition 3.1.

In the following sections, we go through these steps one by one. We will *not* assume from the beginning that $G = SR$ or \mathbb{Z} but we shall add conditions on G (and φ) as we go, in turn proving Theorem 1.9. It will turn out that some of these conditions are known for all ribbon groups and some are conjectural. For the groups SR and \mathbb{Z} we will prove all conditions in Section 4.

3.2 The Poincaré duality condition

We will use the following conventions. If $\tilde{X} \rightarrow X$ is the universal cover then $C_*(\tilde{X})$ has a right $\mathbb{Z}[\pi_1(X)]$ -module structure. Given a left $\mathbb{Z}[\pi_1(X)]$ -module P we can consider $H_*(X; P) := H_*(C_*(\tilde{X}) \otimes_{\mathbb{Z}[\pi_1(X)]} P)$. Using the usual involution on group rings given by $\bar{g} = g^{-1}$ we can turn left $\mathbb{Z}[G]$ -modules into right $\mathbb{Z}[G]$ -modules. We define $H^*(X; P) := H_*(\text{Hom}_{\mathbb{Z}[\pi_1(X)]}(C_*(\tilde{X}), P))$.

Definition [31] Let $Y \subset X$ be CW-complexes, write $G := \pi_1(X)$. Then (X, Y) is called a Poincaré pair of dimension n if there exists $[X] \in H_n(X)$, such that

$$\begin{aligned} \cap[X]: H^i(X, Y; \mathbb{Z}[G]) &\longrightarrow H_{n-i}(X; \mathbb{Z}[G]) \\ \cap\partial[X]: H^i(Y; \mathbb{Z}[G]) &\longrightarrow H_{n-i-1}(Y; \mathbb{Z}[G]) \end{aligned} \quad (\cap)$$

are isomorphisms of $\mathbb{Z}[G]$ -right modules. $[X]$ is called the fundamental homology class of (X, Y) .

Note that if (X, Y) is a Poincaré complex, then from the long exact homology and cohomology sequences it follows that

$$\cap[X]: H^i(X; \mathbb{Z}[G]) \rightarrow H_{n-i}(X, Y; \mathbb{Z}[G])$$

is an isomorphism as well. In our case, Y will be the 3-manifold M_K so that the second condition on $\partial[X]$ will be satisfied. Recall that we have an inclusion $\varphi: M_K \hookrightarrow K(G, 1)$ that induces an epimorphism of fundamental groups. For brevity we set

$$M := M_K \quad \text{and} \quad X := K(G, 1).$$

Recall that if (X, M) is a finite 4-dimensional Poincaré pair, we say that (M, φ) satisfies the *Poincaré duality* condition.

Lemma 3.2 *Assume that G satisfies $H_3(G) = 0$ and $H^i(G; \mathbb{Z}[G]) = 0$ for $i > 2$. Then (M, φ) satisfies the Poincaré duality condition if and only if*

$$\varphi^*: H^i(G; \mathbb{Z}[G]) \longrightarrow H^i(M; \mathbb{Z}[G])$$

is an isomorphism for $i = 1, 2$.

Remark In Section 4 we will show that the above assumptions are satisfied for $G = SR$. In this case $H^2(G; \mathbb{Z}[G]) \neq 0$ (cf Lemma 4.3) which shows that the Poincaré duality condition in general can not be simplified to $H^2(M_K; \mathbb{Z}[G]) = 0$. Note also that the lemma implies that $H_i(G) = 0$ for all $i \geq 3$.

Proof We first show the “only if” direction. In that case $H^{4-i}(X, M; \mathbb{Z}[G]) \cong H_i(X; \mathbb{Z}[G])$. But $H_i(X; \mathbb{Z}[G]) = 0$ for $i \neq 0$ since this is the homology of the G -cover of X which is contractible since $X = K(G, 1)$. The claim now follows from the long exact cohomology sequence with $\mathbb{Z}[G]$ -coefficients. We now turn to the proof of the “if” direction. By the long exact homology sequence of (X, M) , with \mathbb{Z} -coefficients, and the vanishing of $H_3(G) = H_3(X)$ we can choose a class $[X] \in H_4(X, M)$ that maps to the fundamental class $[M] \in H_3(M)$ under the boundary map. Cap product with this class induces maps as

in (\cap) above and we need to check that they are isomorphisms. These maps are the left (or right) most vertical arrows in the commutative diagram of long exact sequences (with $\mathbb{Z}[G]$ -coefficients understood):

$$\begin{array}{ccccccc}
 \rightarrow & H^i(X, M) & \rightarrow & H^i(X) & \rightarrow & H^i(M) & \rightarrow & H^{i+1}(X, M) \\
 & \downarrow \cap(-1)^i[X] & & \downarrow \cap(-1)^i[X] & & \downarrow \cap(-1)^{i+1}[M] & & \downarrow \cap(-1)^{i+1}[X] \\
 \rightarrow & H_{4-i}(X) & \rightarrow & H_{4-i}(X, M) & \rightarrow & H_{3-i}(M) & \rightarrow & H_{4-(i+1)}(X)
 \end{array}$$

Recall that $H_i(X; \mathbb{Z}[G]) = 0$ for $i \neq 0$. Therefore, we need to show in particular that $H^i(X, M; \mathbb{Z}[G]) = 0$ for $i \neq 4$. Note that

$$H_{4-i}(X, M; \mathbb{Z}[G]) \cong H_{3-i}(M; \mathbb{Z}[G]) \quad \text{for } i \neq 3.$$

Since the maps $\cap[M]$ are isomorphisms it suffices to show that for all $i \neq 3$ the maps

$$\varphi^*: H^i(X; \mathbb{Z}[G]) \longrightarrow H^i(M; \mathbb{Z}[G])$$

are isomorphisms. For $i = 1, 2$ this is our assumption so it suffices to discuss the other cases. For $i = 0$ both groups are zero since G has infinite order. For $i > 3$ again both groups are zero, for X this is our assumption and for M it follows from $\dim M = 3$. Finally, we need to discuss the special case $i = 3$ in the diagram above. Then

$$H_0(M; \mathbb{Z}[G]) \cong \mathbb{Z} \cong H_0(X; \mathbb{Z}[G])$$

and by assumption $H^i(X; \mathbb{Z}[G]) = 0$ for $i = 3, 4$. It follows that the boundary map $H^3(M; \mathbb{Z}[G]) \rightarrow H^4(X, M; \mathbb{Z}[G])$ is an isomorphism and by commutativity of the diagram the last map in question

$$\cap[X]: H^4(X, M; \mathbb{Z}[G]) \longrightarrow H_0(X; \mathbb{Z}[G])$$

is also an isomorphism. □

Lemma 3.3 *Let G satisfy $H_3(G) = 0$ and $H^i(G; \mathbb{Z}[G]) = 0$ for $i > 2$. Furthermore, assume that $\text{Hom}_{\mathbb{Z}[G]}(H_i(M; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$ for $i = 1, 2$. Then (M, φ) satisfies the Poincaré duality condition if and only if the (Ext) condition from Theorem 1.3 holds: $\text{Ext}_{\mathbb{Z}[G]}^1(H_1(M; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$.*

Proof Denote the universal cover of M by \widetilde{M} . Write $\pi := \pi_1(M)$. Note that we have a chain isomorphism of right $\mathbb{Z}[G]$ -module complexes given by

$$\begin{array}{ccc}
 \text{Hom}_{\mathbb{Z}[\pi]}(C_*(\widetilde{M}), \mathbb{Z}[G]) & \rightarrow & \text{Hom}_{\mathbb{Z}[G]}(C_*(\widetilde{M}) \otimes_{\mathbb{Z}[\pi]} \mathbb{Z}[G], \mathbb{Z}[G]) \\
 \phi & \mapsto & (c \otimes f \mapsto \phi(c)f).
 \end{array}$$

Therefore $H^*(M; \mathbb{Z}[G]) \cong H_*(\text{Hom}_{\mathbb{Z}[G]}(C_*(\widetilde{M}) \otimes_{\mathbb{Z}[\pi]} \mathbb{Z}[G], \mathbb{Z}[G]))$. We now apply the universal coefficient spectral sequence (UCSS). This has an E_2 -term

$$E_2^{p,q} = \text{Ext}_{\mathbb{Z}[G]}^p(H_q(M; \mathbb{Z}[G]), \mathbb{Z}[G]),$$

differentials d_r of degree $(r, 1 - r)$ and converges to

$$H^{p+q}(M; \mathbb{Z}[G]) \cong H_{p+q}(\text{Hom}_{\mathbb{Z}[G]}(C_*(\widetilde{M}) \otimes_{\mathbb{Z}[\pi]} \mathbb{Z}[G], \mathbb{Z}[G])),$$

cf [20, Theorem 2.7] for more details. We use that the edge homomorphism at $q = 0$ of the spectral sequence is the map

$$\varphi^*: \text{Ext}_{\mathbb{Z}[G]}^p(H_0(M; \mathbb{Z}[G]), \mathbb{Z}[G]) \cong H^p(G; \mathbb{Z}[G]) \longrightarrow H^p(M; \mathbb{Z}[G]).$$

By Lemma 3.2 we only need to verify that this is an isomorphism for $p = 1, 2$ if and only if condition (Ext) holds. For $p = 1$ this follows immediately from our assumption $\text{Hom}_{\mathbb{Z}[G]}(H_1(M; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$. For $p = 2$ we first observe that since $H^3(G; \mathbb{Z}[G]) = 0$ there are no possible d_2 -differentials into the $E_2^{1,1}$ spot. Since $\text{Hom}_{\mathbb{Z}[G]}(H_2(M; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$, we get a short exact sequence

$$0 \longrightarrow \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M; \mathbb{Z}[G]), \mathbb{Z}[G]) \longrightarrow H^2(G; \mathbb{Z}[G]) \xrightarrow{\varphi^*} H^2(M; \mathbb{Z}[G]) \longrightarrow 0$$

showing that the condition (Ext) holds if and only if φ^* is an isomorphism. \square

Let G be any group with $H_1(G) = \mathbb{Z}$. Then we define $\Delta_G(t) \in \mathbb{Z}[t^{\pm 1}]$ to be the order of the $\mathbb{Z}[t^{\pm 1}]$ -module $H_1(G, \mathbb{Z}[t^{\pm 1}]) \cong H_1(G^{(1)}, \mathbb{Z})$. Note that Δ_G is well-defined up to multiplication by a unit in $\mathbb{Z}[t^{\pm 1}]$ and up taking the natural involution $t \mapsto t^{-1}$. For example if $G = SR$, then $\Delta_G(t) = t - 2$.

Corollary 3.4 *Let G and M satisfy all the conditions from Lemma 3.3, including the (Ext) condition. Then*

$$\Delta_K(t) = \Delta_G(t)\Delta_G(t^{-1}).$$

In particular $\text{Arf}(K) = 0$.

Proof By Lemma 3.3 $(K(G, 1), M_K)$ is a Poincaré pair. Since

$$H_i(M_K; \mathbb{Z}) \xrightarrow{\cong} H_i(K(G, 1); \mathbb{Z})$$

for all i it follows from a well-known argument that

$$0 = H_i(M_K; \mathbb{Q}(t)) \xrightarrow{\cong} H_i(K(G, 1); \mathbb{Q}(t))$$

for all i . In particular $H_i(K(G, 1); \mathbb{Z}[t^{\pm 1}])$ is $\mathbb{Z}[t^{\pm 1}]$ -torsion for all i . The corollary now follows from the long exact sequence of $(K(G, 1), M_K)$ with $\mathbb{Z}[t^{\pm 1}]$ -coefficients, duality, and the fact that the alternating product of orders of a

long exact sequence equals one (cf [19, Lemma 5, p. 76]). The Arf invariant $\text{Arf}(K) \in \mathbb{Z}/2$ of a knot K has the well-known property that it equals zero if $\Delta_K(-1) \equiv \pm 1 \pmod{8}$, and 1 otherwise. \square

We shall now work through the remaining steps outlined in Section 3.1. We have a Poincaré pair (X, M) where $X = K(G, 1)$ and $M = M_K$. Clearly $\pi_1(X)$ is normally generated by the image of a meridian for K since φ is surjective and since any meridian normally generates $\pi_1(M_K)$. Furthermore $H_1(X) \cong H_1(G) \cong \mathbb{Z}$ and $H_2(X) = H_2(G) = 0$. It follows from the homology exact sequence of the pair (X, M) , Poincaré duality, and the fact that φ is an isomorphism on H_1 that $H_3(X) = 0$.

3.3 The degree 1 normal map

We show that the stable Spivak normal bundle of (X, M) has a linear reduction. It seems well known to experts that this is always true in the oriented case in 4 dimensions but we could not find an explicit reference. So here is a rather ad hoc argument: Since M is orientable, its tangent bundle is trivial and so is its stable normal bundle. We claim that the stable Spivak normal bundle of X is also trivial: Let BS be the classifying space of such (oriented) bundles. Its homotopy groups are the (shifted) stable homotopy groups of spheres, starting with

$$\pi_2 BS \cong \mathbb{Z}/2 \cong \pi_3 BS \quad \text{and} \quad \pi_4 BS \cong \mathbb{Z}/24.$$

It follows that for all i we have $H^i(X; \pi_i BS) = 0$ which shows that the classifying map $X \rightarrow BS$ of the stable Spivak normal bundle is trivial. Finally, it is clear that, up to homotopy, this trivial map can be lifted (trivially) through the fibration $B\text{SO} \rightarrow BS$, having the trivial map on the boundary M . From the usual transversality theory we obtain a degree 1 normal map from a manifold pair

$$f: (N, M) \rightarrow (X, M)$$

that is the identity on the boundary. Note that since the stable normal bundle of X is trivial, so is that of N . In particular, N is spin. Another approach to finding f is to prove that (M, φ) represents the zero element in the spin-bordism group $\Omega_4^{\text{Spin}}(X)$. The fact that this element is zero comes from comparing with the Poincaré duality spin bordism group in which X itself gives a zero bordism. Even though this is not really important for our main argument, we next show that f is unique in a certain sense: In the spin case the normal cobordism group of degree 1 normal maps is isomorphic to

$$H_2(X; \mathbb{Z}/2) \oplus 8 \cdot \mathbb{Z}$$

where the $8 \cdot \mathbb{Z}$ summand is the difference of ordinary signatures, $\sigma(N) - \sigma(X)$. The first summand vanishes in our case and so does $\sigma(X)$. By adding copies of Freedman's E_8 -manifold to N , we may assume that $\sigma(N) = 0$. This is just another way of saying that we work with the *reduced* normal cobordism group.

3.4 The surgery obstruction

There is a well defined surgery obstruction $\sigma(f)$ in $L_4^h(\mathbb{Z}[G])$ which in our case is simply the intersection form on $\pi_2 N$. The first step is 'surgery below the middle dimension' which makes f 2-connected. The surgery obstruction then measures the kernel of f in the middle dimension which in our case is in π_2 . To make this precise, recall the following definition from [31, p. 47].

Definition A *quadratic form* over $\mathbb{Z}[G]$ is defined to be a triple (H, λ, μ) with H a free $\mathbb{Z}[G]$ -module,

$$\lambda: H \times H \rightarrow \mathbb{Z}[G]$$

a non-singular hermitian form and

$$\mu: H \rightarrow \mathbb{Z}[G]/\langle a - \bar{a} \mid a \in \mathbb{Z}[G] \rangle$$

a quadratic refinement. Here a form is *non-singular* if the induced map $H \rightarrow \text{Hom}_{\mathbb{Z}[G]}(H; \mathbb{Z}[G])$ is an isomorphism. A form isomorphic to a direct sum of the form $(\mathbb{Z}[G] \cdot e \oplus \mathbb{Z}[G] \cdot f, \lambda, \mu)$, where $\lambda(e, f) = 1$ and $\mu(e) = \mu(f) = 0$, is called a *hyperbolic form*.

It should be pointed out that in the oriented case, where the involution on $\mathbb{Z}[G]$ is given by $\bar{g} := g^{-1}$, the quadratic refinement μ is completely determined by the hermitian form λ . Its only role is to make sure that λ is *even* in the sense that for every $h \in H$ there is an $m \in \mathbb{Z}[G]$ such that

$$\lambda(h, h) = m + \bar{m} \tag{even}$$

The main examples of hermitian forms come from the intersection form of 4-manifolds, where $G = \pi_1 W$ and $(H, \lambda) = (\pi_2 W^4, \lambda_W)$. If $h \in \pi_2 W$ is represented by an immersed 2-sphere S in W , then one can look at the self-intersections $m(S)$ that are related to the intersection λ_W of S and a parallel push-off by the following formula:

$$\lambda_W(S, S) = m(S) + \bar{m}(S) + e(S) \cdot 1$$

Here $e(S) \in \mathbb{Z}$ denotes the normal Euler class of S . Note that the coefficient of $1 \in G$ in $m(S)$ can be changed arbitrarily by a (nonregular) homotopy, the so

called *cuspidal move*. This also changes $e(S)$ so as to make the above formula still hold (the left hand side only depends on the homotopy class of S). It follows that the intersection form λ on π_2 of a 4-manifold is even in the above sense if and only if $e(S)$ is an even integer, ie, the second Stiefel–Whitney class $w_2(S)$ vanishes. That is why we will completely ignore the quadratic refinement μ in the following, only making sure that our manifolds are spin. Note that for general spin 4-manifolds W with fundamental group G , the intersection form λ_W on $\pi_2 W$ is not a quadratic form in the above sense. The problems are that in general $\pi_2 W$ is not free and λ_W is not non-singular. However, given a 2-connected degree 1 map $f: N \rightarrow X$, one can restrict λ_N to the kernel of f on π_2 . Then both of these conditions can be arranged after stabilizing N by copies of $S^2 \times S^2$, [31, p. 26]. Moreover, if w_2 vanishes on 2-spheres in this kernel then a quadratic refinement exists by the above considerations. If f is a normal map (in addition to having degree 1) then this last condition is obvious. In our setting, $\pi_2 K(G, 1) = 0$ so that we automatically work on the kernel of f . Moreover, we saw that N is spin so that the intersection form λ_N on $\pi_2 N$ is even and hence represents a unique quadratic form, up to the stabilization with hyperbolic forms. This motivates the following definition. Consider the semigroup of quadratic forms under direct sum. We say that forms X_1, X_2 are equivalent if there exist hyperbolic forms H_1, H_2 , such that $X_1 \oplus H_1$ and $X_2 \oplus H_2$ are isomorphic. The set of equivalence classes form a group (cf [27, p. 249]), denoted by $L_4^h(\mathbb{Z}[G])$. As discussed above, $(\pi_2 N, \lambda_N)$ represents an element in this group.

Theorem 3.5 *The ordinary signature σ induces isomorphisms*

- (1) $L_4^h(\mathbb{Z}) \xrightarrow{\cong} \mathbb{Z}$, $(H, \lambda, \mu) \mapsto \sigma(\lambda)/8$
- (2) $L_4^h(\mathbb{Z}[G]) \xrightarrow{\cong} L_4^h(\mathbb{Z})$ for $G = \mathbb{Z}$ or $G = SR$.

The first statement is well-known, see for example [31, Theorem 13A.1]. The second statement is well-known in the case that $G = \mathbb{Z}$ (cf [26]). We prove the case $G = SR$ in Section 4. In general if G is a ribbon group, then $L_4^h(\mathbb{Z}[G]) \rightarrow L_4^h(\mathbb{Z})$ is an isomorphism if the Whitehead conjecture and the Farrell–Jones conjecture hold. This has been shown in many interesting cases, cf [1] for the case of knot groups. By the computations in Section 3.3, the surgery obstruction $\sigma(f) = \lambda_N$ actually only depends on the original data (M, φ) if we assume that $\sigma(N) = 0$, ie, that it lies in the reduced L-group

$$\sigma(M, \varphi) = \sigma(f) = \lambda_N \in \tilde{L}_4^h(\mathbb{Z}[G]) := \ker(L_4^h(\mathbb{Z}[G]) \rightarrow L_4^h(\mathbb{Z}))$$

This element is hence an obstruction for finding a h-ribbon for K with epimorphism $\phi: \pi_1 M \twoheadrightarrow G$. If the reduced L-group vanishes then, after further

stabilization by $S^2 \times S^2$, we may assume that $\pi_2 N$ has hyperbolic intersection form.

3.5 Constructing the h-ribbon disk

The assumptions of Theorem 1.9 say that the reduced L-group vanishes and that the topological surgery sequence (\mathcal{S}) is exact for our fundamental group. Therefore, one gets a topological manifold W together with a homotopy equivalence $(W, M_K) \rightarrow (K(G, 1), M_K)$. Hence we found our h-ribbon by Proposition 3.1 and we finished the proof of Theorem 1.9.

3.6 Proof of Theorem 1.3

To construct a ribbon disk we use Theorem 1.9 that we just finished proving. For $G = SR$, we will show all the required properties in Section 4. For $G = \mathbb{Z}$ they are easy to check, for example the conditions on Hom follow from the fact that the Alexander module $H_1(M_K; \mathbb{Z}[\mathbb{Z}])$ is a $\mathbb{Z}[\mathbb{Z}]$ -torsion module. Moreover,

$$\text{Ext}_{\mathbb{Z}[\mathbb{Z}]}^1(H_1(M_K; \mathbb{Z}[\mathbb{Z}]), \mathbb{Z}[\mathbb{Z}]) \cong H_1(M_K; \mathbb{Z}[\mathbb{Z}])$$

so that our (Ext) condition simply means that the Alexander module (or, equivalently, the Alexander polynomial) of K is trivial. Conversely, assume that there exists a h-ribbon D for K with $\pi_1(N_D) \cong G$. Then it follows from arguments as in the proof of Theorem 4.4 in [5] that the Blanchfield form $B\ell(G)$ always vanishes on

$$\text{Ker}\{H_1(M_K; \mathbb{Z}[G]) \longrightarrow H_1(N_D; \mathbb{Z}[G])\},$$

In our case this group equals $H_1(M_K; \mathbb{Z}[G])$ since $H_1(N_D; \mathbb{Z}[G]) = 0$. In the Section 5 we will recall this Blanchfield form and show in Lemma 5.1 that its vanishing is indeed equivalent to our (Ext) condition.

4 Properties of the solvable ribbon group SR

The purpose of this section is to prove that the assumptions of Lemma 3.3 are satisfied for the group $G = SR$:

Lemma 4.1 *The group $G = SR$ satisfies $H_3(G) = 0$ and $H^i(G; \mathbb{Z}[G]) = 0$ for $i > 2$. Furthermore, for any knot K and any epimorphism $\pi_1(M_K) \twoheadrightarrow G$ one has*

$$\text{Hom}_{\mathbb{Z}[G]}(H_i(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0 \quad \text{for } i = 1, 2.$$

A group G is called poly-torsion-free-abelian (PTFA) if there exists a filtration

$$1 = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_{n-1} \triangleleft G_n = G$$

such that G_i/G_{i-1} is torsion free abelian. As we pointed out in Section 2 the only solvable ribbon groups are \mathbb{Z} and SR and clearly both are PTFA. If G is a PTFA group then the group ring $\mathbb{Z}[G]$ satisfies the *Ore condition* and therefore has an *Ore localization*, cf [5, Proposition 2.5]

$$Q(G) := \mathbb{Z}[G](\mathbb{Z}[G] \setminus 0)^{-1}$$

which is a skew field. Therefore, every $Q(G)$ -module is free and its rank is well-defined. As a localization, $Q(G)$ is flat as a right (and left) $\mathbb{Z}[G]$ -module. Moreover, the $\mathbb{Z}[G]$ -torsion part of a module is a submodule (unlike for general non-commutative rings). Let K be a knot and $\pi_1(M_K) \twoheadrightarrow G$ be an epimorphism onto a PTFA group. From [5, Proposition 2.11] it follows that

$$H_1(M_K; \mathbb{Z}[G]) \otimes_{\mathbb{Z}[G]} Q(G) \cong H_1(M_K; Q(G)) = 0,$$

ie, $H_1(M_K; \mathbb{Z}[G])$ is $\mathbb{Z}[G]$ -torsion. In particular, the required condition

$$\mathrm{Hom}_{\mathbb{Z}[G]}(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$$

in Lemma 4.1 follows. Furthermore,

$$H_0(M_K; Q(G)) \cong H_0(M_K; \mathbb{Z}[G]) \otimes_{\mathbb{Z}[G]} Q(G) \cong \mathbb{Z} \otimes_{\mathbb{Z}[G]} Q(G) = 0$$

and similarly $H_3(M_K; Q(G)) = 0$ since $H_3(M_K; \mathbb{Z}[G]) = 0$. The Euler characteristics of M_K with \mathbb{Z} and $Q(G)$ coefficients agree by the usual argument and hence

$$\chi_{Q(G)}(H_*(M_K; Q(G))) = \chi_{\mathbb{Z}}(H_*(M_K; \mathbb{Z})) = 0.$$

It follows that

$$H_2(M_K; \mathbb{Z}[G]) \otimes_{\mathbb{Z}[G]} Q(G) \cong H_2(M_K; Q(G)) = 0,$$

Therefore $H_1(M_K; Q(G)) = 0$ and hence $\mathrm{Hom}_{\mathbb{Z}[G]}(H_2(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$ because $H_2(M_K; \mathbb{Z}[G])$ is again $\mathbb{Z}[G]$ -torsion. So another required condition in Lemma 4.1 follows:

$$\mathrm{Hom}_{\mathbb{Z}[G]}(H_2(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0.$$

The following result finishes up our task of showing SR has all the required properties.

Lemma 4.2 *The group $G = SR$ is aspherical, in particular $\mathrm{Ext}_{\mathbb{Z}[G]}^i(\mathbb{Z}, \mathbb{Z}[G]) = 0$ for $i > 2$ and $H_3(G) = 0$.*

Proof Let D be a ribbon disk with complement N_D and fundamental group $\pi_1(N_D) = G = SR$. Recall that by Alexander duality $H_2(N_D) = 0$. We will show that N_D is a $K(G, 1)$. First note that N_D is homotopy equivalent to a 2-complex N . By the Hurewicz theorem it suffices to prove the vanishing of $\pi_2(N) \cong H_2(\tilde{N})$. Let $Q(G)$ be the Ore localization of $\mathbb{Z}[G]$. By the same arguments as above for M_K , involving Euler characteristics, one shows that

$$H_2(\tilde{N}) \otimes_{\mathbb{Z}[G]} Q(G) \cong H_2(N; \mathbb{Z}[G]) \otimes_{\mathbb{Z}[G]} Q(G) = 0.$$

Now consider the following commutative diagram

$$\begin{array}{ccccc} 0 & \rightarrow & H_2(\tilde{N}) & \hookrightarrow & C_2(\tilde{N}) \\ & & \downarrow & & \downarrow \\ 0 & \rightarrow & H_2(\tilde{N}) \otimes_{\mathbb{Z}[G]} Q(G) & \hookrightarrow & C_2(\tilde{N}) \otimes_{\mathbb{Z}[G]} Q(G). \end{array}$$

The second vertical map is injective since $C_2(\tilde{N})$ is a free $\mathbb{Z}[G]$ -module, hence the first vertical map is injective as well, hence $H_2(\tilde{N}) = 0$. \square

Remark We could have used the well known fact that a one-relator group is aspherical if the relation is not a proper power (so in particular the group is torsion free). However, a similar argument as above will also be used in the proof of Lemma 4.3. Locally indicable ribbon groups are also known to be aspherical.

The following result is not needed in the rest of the paper but we include it for the interested reader. The nontriviality of the homology group in question made it clear that some more naive formulations of the Poincaré duality condition must fail. Recall from Section 2 that SR has the presentation

$$SR = \langle a, c \mid aca^{-1} = c^2 \rangle.$$

Lemma 4.3 *Let $G := SR$, then $H^2(G; \mathbb{Z}[G])$ maps onto $\mathbb{Z}[1/2]$. More precisely, as a right $\mathbb{Z}[G]$ -module, $H^2(G; \mathbb{Z}[G])$ is the quotient of $\mathbb{Z}[G]$ by the right ideal generated by*

$$1 - aca^{-1} \quad \text{and} \quad a - aca^{-1}c^{-1} - aca^{-1}c^{-2}.$$

Dividing $\mathbb{Z}[G]$ by the two-sided ideal generated by the same elements gives the ring $\mathbb{Z}[1/2]$.

Proof The proof of Lemma 4.1 shows that the 2-complex associated to the above presentation is a $K(G, 1)$. Therefore, we can calculate $H^2(G; \mathbb{Z}[G])$ from the short resolution

$$0 \longrightarrow \mathbb{Z}[G] \longrightarrow \mathbb{Z}[G]^2 \longrightarrow \mathbb{Z}[G] \xrightarrow{\epsilon} \mathbb{Z} \longrightarrow 0$$

where the first map is given by the Fox derivatives ∂_a and ∂_c of the relation $aca^{-1}c^{-2}$. A straightforward calculation using Fox derivatives ‘from the left’ gives

$$\partial_a = 1 - aca^{-1} \quad \text{and} \quad \partial_c = a - aca^{-1}c^{-1} - aca^{-1}c^{-2}$$

If we now decide to quotient by the two-sided ideal generated by the first relation, we find that the defining relation forces $c = 1$ and hence we are left with $\mathbb{Z}[\mathbb{Z}]$, generated by a . The second relation then introduces the relation $a = 2$ into this commutative ring which gives the ring $\mathbb{Z}[1/2]$. \square

Computation of $L_4^h(\mathbb{Z}[SR])$

Lemma 4.4 *The inclusion map $\mathbb{Z} \rightarrow \mathbb{Z}[\mathbb{Z} \times \mathbb{Z}[1/2]]$ induces an isomorphism $L_4^h(\mathbb{Z}) \rightarrow L_4^h(\mathbb{Z}[\mathbb{Z} \times \mathbb{Z}[1/2]])$.*

In order to prove this lemma, we need a theorem by Ranicki, which in turn needs the notion of L_n -groups for any n . We refer to [25] for the definition of these groups. We recall that the Whitehead group $Wh(G)$ for a group G is defined as $Wh(G) = K_1(\mathbb{Z}[G]) / \pm G$ (cf [27, p. 172] for a definition of $K_1(\mathbb{Z}[G])$).

Theorem 4.5 [24] *Let G be a group with $Wh(G) = 0$ and let $\alpha: \mathbb{Z}[G] \rightarrow \mathbb{Z}[G]$ be an automorphism, then there exists a long exact sequence*

$$\dots \rightarrow L_n(\mathbb{Z}[G]) \xrightarrow{1-\alpha_*} L_n(\mathbb{Z}[G]) \rightarrow L_n(\mathbb{Z}[G]^\alpha[t, t^{-1}]) \rightarrow L_{n-1}(\mathbb{Z}[G]) \rightarrow \dots,$$

where $\mathbb{Z}[G]^\alpha[t, t^{-1}]$ denotes the twisted Laurent ring, ie, for $a_1, a_2 \in \mathbb{Z}[G]$ we have $a_1 t^{n_1} \cdot a_2 t^{n_2} = a_1 \alpha(a_2)^{n_1} t^{n_1+n_2}$.

Remark Since $Wh(G) = 0$, we don’t have to distinguish between L^s and L^h . We will therefore henceforth drop any decorations.

We’ll make use of the fact that $\mathbb{Z}[1/2]$ is the direct limit of the direct system $\mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{2} \dots$. We’ll therefore write $\mathbb{Z}[1/2] = \varinjlim \mathbb{Z}$. Denote the map $\cdot 2: \mathbb{Z}[1/2] \rightarrow \mathbb{Z}[1/2]$ by α ; then $\mathbb{Z}[\mathbb{Z} \times \mathbb{Z}[1/2]] \cong \mathbb{Z}[\mathbb{Z}[1/2]]^\alpha[t, t^{-1}]$.

Claim $Wh(\mathbb{Z}[1/2]) = 0$.

The determinant map $\det: K_1(\mathbb{Z}[\mathbb{Z}]) \rightarrow \mathbb{Z} \times \{\pm 1\}$ is an isomorphism (cf [27, p. 172]). The K_1 functor commutes with direct limits and α commutes with the determinant maps, hence $\det: K_1(\mathbb{Z}[\mathbb{Z}[1/2]]) \rightarrow \mathbb{Z}[\mathbb{Z}[1/2]] \times \{\pm 1\}$ is an isomorphism as well. It now follows immediately that $Wh(\mathbb{Z}[1/2]) = 0$.

By Theorem 4.5 there therefore exists an exact sequence

$$\begin{aligned} \dots \rightarrow L_n(\mathbb{Z}[\mathbb{Z}[1/2]]) &\xrightarrow{1-\alpha_*} L_n(\mathbb{Z}[\mathbb{Z}[1/2]]) \rightarrow L_n(\mathbb{Z}[\mathbb{Z}[1/2]]^\alpha[t, t^{-1}]) \rightarrow \\ &\rightarrow L_{n-1}(\mathbb{Z}[\mathbb{Z}[1/2]]) \xrightarrow{1-\alpha_*} \dots \end{aligned}$$

It is clear that the proposition follows once we prove the following claim.

- Claim**
- (1) $L_4(\mathbb{Z}) \rightarrow L_4(\mathbb{Z}[\mathbb{Z}[1/2]])$ is an isomorphism,
 - (2) $\alpha_*: L_4(\mathbb{Z}[\mathbb{Z}[1/2]]) \rightarrow L_4(\mathbb{Z}[\mathbb{Z}[1/2]])$ is the identity map,
 - (3) $L_3(\mathbb{Z}[\mathbb{Z}[1/2]]) = 0$.

We recall that (cf [31])

$$L_n(\mathbb{Z}) = \begin{cases} 0 & \text{if } n \equiv 1 \pmod{2} \\ \mathbb{Z} & \text{if } n \equiv 0 \pmod{4} \\ \mathbb{Z}/2 & \text{if } n \equiv 2 \pmod{4}. \end{cases}$$

From Theorem 4.5 it follows that $L_4(\mathbb{Z}) \xrightarrow{\cong} L_4(\mathbb{Z}[\mathbb{Z}])$ via the map induced by the inclusion $\mathbb{Z} \rightarrow \mathbb{Z}[\mathbb{Z}]$. The inverse $L_4(\mathbb{Z}[\mathbb{Z}]) \rightarrow L_4(\mathbb{Z})$ is given by tensoring with \mathbb{Z} , considered as a $\mathbb{Z}[\mathbb{Z}]$ -module via the map $t \mapsto 1$. In particular the map $\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}$ induces the identity on the L_4 group of the group ring, ie, on $L_4(\mathbb{Z}[\mathbb{Z}])$. From the fact that the L -functor commutes with direct limits, we immediately get the first two statements. From [31, p. 181] we get the following commutative diagram

$$\begin{array}{ccc} L_3(\mathbb{Z}[\mathbb{Z}]) & \rightarrow & L_3(\mathbb{Z}[\mathbb{Z}/2]) \\ \alpha_* \downarrow & & \downarrow \alpha_* \\ L_3(\mathbb{Z}[\mathbb{Z}]) & \rightarrow & L_3(\mathbb{Z}[\mathbb{Z}/2]), \end{array}$$

where α denotes multiplication by two. In particular $\alpha_*: L_3(\mathbb{Z}[\mathbb{Z}/2]) \rightarrow L_3(\mathbb{Z}[\mathbb{Z}/2])$ factors through $L_3(\mathbb{Z}) = 0$. Hence $\alpha_*: L_3(\mathbb{Z}[\mathbb{Z}]) \rightarrow L_3(\mathbb{Z}[\mathbb{Z}])$ is the zero map, taking direct limits we see that $L_3(\mathbb{Z}[\mathbb{Z}[1/2]]) = 0$. This completes the proof of Lemma 4.4.

5 Non-commutative Blanchfield forms

Let G be a PTFA-group and $\varphi: M_K \twoheadrightarrow G$ a homomorphism. Note that the involution on $\mathbb{Z}[G]$ extends to an involution on $Q(G)$ and on $Q(G)/\mathbb{Z}[G]$. Let $\pi := \pi_1(M_K)$. Note that the map

$$\begin{aligned} \text{Hom}_{\mathbb{Z}[\pi]}(C_*(\tilde{M}_K), Q(G)/\mathbb{Z}[G]) &\rightarrow \text{Hom}_{\mathbb{Z}[G]}(C_*(\tilde{M}_K) \otimes_{\mathbb{Z}[\pi]} \mathbb{Z}[G], Q(G)/\mathbb{Z}[G]) \\ \phi &\mapsto (c \otimes f \mapsto \phi(c)f) \end{aligned}$$

is well-defined and induces an evaluation map

$$H^1(M_K; Q(G)/\mathbb{Z}[G]) \longrightarrow \text{Hom}_{\mathbb{Z}[G]}(H_1(M_K; \mathbb{Z}[G]), Q(G)/\mathbb{Z}[G]).$$

Now consider

$$\begin{aligned} H_1(M_K; \mathbb{Z}[G]) &\xrightarrow{\cong} H^2(M_K; \mathbb{Z}[G]) \xleftarrow{\cong} H^1(M_K; Q(G)/\mathbb{Z}[G]) \\ &\longrightarrow \text{Hom}_{\mathbb{Z}[G]}(H_1(M_K; \mathbb{Z}[G]), Q(G)/\mathbb{Z}[G]) \end{aligned}$$

ie, the composition of Poincaré duality, the inverse of the Bockstein homomorphism for the coefficient sequence $0 \rightarrow \mathbb{Z}[G] \rightarrow Q(G) \rightarrow Q(G)/\mathbb{Z}[G] \rightarrow 0$ and the above evaluation map.

Note that the second map is an isomorphism since the homology and hence the cohomology with $Q(G)$ coefficients vanishes. This map defines the hermitian *Blanchfield pairing*, cf [8, Theorem 5.1]

$$Bl(G): H_1(M_K; \mathbb{Z}[G]) \times H_1(M_K; \mathbb{Z}[G]) \longrightarrow Q(G)/\mathbb{Z}[G].$$

Lemma 5.1 *For $G = \mathbb{Z}$ or SR , the condition (Ext) from Theorem 1.3 is equivalent to the vanishing of the Blanchfield form $Bl(G)$.*

The remark after Lemma 3.2 shows that the vanishing of the Blanchfield pairing $Bl(G)$ is a weaker statement than the vanishing of the corresponding homology group $H_1(M_K; \mathbb{Z}[G]) \cong H^2(M_K; \mathbb{Z}[G])$. In particular, this shows that $Bl(G)$ will in general be singular.

Proof of Lemma 5.1 From the long exact Ext-sequence corresponding to

$$0 \longrightarrow \mathbb{Z}[G] \longrightarrow Q(G) \longrightarrow Q(G)/\mathbb{Z}[G] \longrightarrow 0$$

it follows that

$$\begin{aligned} \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) &\cong \text{Ext}_{\mathbb{Z}[G]}^0(H_1(M_K; \mathbb{Z}[G]), Q(G)/\mathbb{Z}[G]) \\ &\cong \text{Hom}_{\mathbb{Z}[G]}(H_1(M_K; \mathbb{Z}[G]), Q(G)/\mathbb{Z}[G]) \end{aligned}$$

since $\text{Ext}_{\mathbb{Z}[G]}^i(H_1(M_K; \mathbb{Z}[G]), Q(G)) = 0$ for all i (cf [5, Remark 2.8]). We are now done once we show that the homomorphism

$$H^1(M_K; Q(G)/\mathbb{Z}[G]) \longrightarrow \text{Hom}_{\mathbb{Z}[G]}(H_1(M_K; \mathbb{Z}[G]), Q(G)/\mathbb{Z}[G]) \tag{5.2}$$

in the definition of $Bl(G)$ is surjective. As in the proof of Lemma 3.3 we have an isomorphism

$$H^1(M_K; Q(G)/\mathbb{Z}[G]) \cong H_1(\text{Hom}_{\mathbb{Z}[G]}(C_*(\tilde{M}_K) \otimes_{\mathbb{Z}[\pi_1(M)]} \mathbb{Z}[G], Q(G)/\mathbb{Z}[G])).$$

Now applying the UCSS we see that the evaluation map (5.2) is surjective if $\text{Ext}_{\mathbb{Z}[G]}^2(\mathbb{Z}, Q(G)/\mathbb{Z}[G]) = 0$. Let $X = K(SR, 1)$. By Lemma 4.2 we can assume that X is a 2-complex. Then

$$\text{Ext}_{\mathbb{Z}[G]}^2(\mathbb{Z}, Q(G)/\mathbb{Z}[G]) \cong H^2(G; Q(G)/\mathbb{Z}[G]) \cong H^2(X; Q(G)/\mathbb{Z}[G]).$$

Note that $H^i(X; Q(G)) \cong H_i(X; Q(G)) \cong H_i(X; \mathbb{Z}[G]) \otimes_{\mathbb{Z}[G]} Q(G) = 0$ for $i = 2, 3$, in particular it follows that

$$H^2(X; Q(G)/\mathbb{Z}[G]) = H^3(X; \mathbb{Z}[G]) = 0$$

because X is a 2-complex. □

Since $B\ell(\mathbb{Z})$ is nonsingular for any knot K , it vanishes if and only if the Alexander module itself vanishes. This in turn is equivalent to K having trivial Alexander polynomial and to our condition (Ext) for $G = \mathbb{Z}$.

6 The satellite construction

Let K, C be knots. Let $A \subset S^3 \setminus K$ be a curve, unknotted in S^3 . Then $S^3 \setminus \nu A$ is a solid torus. Let $\psi: \partial(\nu A) \rightarrow \partial(\nu C)$ be a diffeomorphism which sends a meridian of A to a longitude of C , and a longitude of A to a meridian of C . The space

$$(S^3 \setminus \nu A) \cup_{\psi} (S^3 \setminus \nu C)$$

is a 3-sphere and the image of K is denoted by $S = S(K, C, A)$. We say S is the satellite knot with companion C , orbit K and axis A . Note that we replaced a tubular neighborhood of C by a knot in a solid torus, namely $K \subset S^3 \setminus \nu A$. Figure 6.1 shows that taking the Whitehead double of a knot is an example for the satellite construction. It is easy to see that

Figure 6.1: Satellite construction with C the trefoil, K the unknot

$$M_S = (M_K \setminus \nu A) \cup_{\partial(\nu A)} (S^3 \setminus \nu C).$$

Obstruction theory shows that the map $\psi^{-1}: \partial(\overline{\nu C}) \rightarrow \partial(\overline{\nu A})$ can be extended to a map $f: S^3 \setminus \nu C \rightarrow \overline{\nu A}$. Combining with the injection $M_K \setminus \nu A \rightarrow M_K$ this defines a map $M_S \rightarrow M_K$. Let $\varphi: \pi_1(M_K) \rightarrow G$ be a homomorphism onto a torsion-free group. Then we get an induced map $\pi_1(M_S) \rightarrow G$.

Lemma 6.2 *If $\varphi(A) = e$, then $H_1(M_S; \mathbb{Z}[G]) \cong H_1(M_K; \mathbb{Z}[G])$, otherwise*

$$H_1(M_S; \mathbb{Z}[G]) \cong H_1(M_K; \mathbb{Z}[G]) \oplus H_1(M_C; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G],$$

where $\mathbb{Z}[G]$ is a $\mathbb{Z}[\mathbb{Z}] \cong \mathbb{Z}[t, t^{-1}]$ module via $t \mapsto \varphi(A)$.

Proof Consider the following commutative diagram of Meyer–Vietoris exact sequences (with $\mathbb{Z}[G]$ –coefficients understood)

$$\begin{array}{ccccccc} H_1(\partial(\overline{\nu A})) & \longrightarrow & H_1(M_K \setminus \nu A) \oplus H_1(S^3 \setminus \nu C) & \longrightarrow & H_1(M_S) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow f & & \\ H_1(\partial(\overline{\nu A})) & \longrightarrow & H_1(M_K \setminus \nu A) \oplus H_1(\overline{\nu A}) & \longrightarrow & H_1(M_K) & \longrightarrow & 0 \end{array}$$

If $\varphi(A) = e$, then the coefficient systems for $\overline{\nu A}$ and for $S^3 \setminus \nu C$ are trivial, hence

$$\begin{aligned} H_1(\overline{\nu A}; \mathbb{Z}[G]) &\cong H_1(\overline{\nu A}; \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{Z}[G] \\ &\cong \mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}[G] \\ &\cong H_1(S^3 \setminus \nu C; \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{Z}[G] \\ &\cong H_1(S^3 \setminus \nu C; \mathbb{Z}[G]). \end{aligned}$$

This immediately implies that $H_1(M_S; \mathbb{Z}[G]) \cong H_1(M_K; \mathbb{Z}[G])$. If $\varphi(A) \neq e$, then $H_1(\overline{\nu A}; \mathbb{Z}[G]) = 0$ since φ is an element of infinite order since G is torsion free. Furthermore $H_1(\partial(\overline{\nu A}))$ is a free $\mathbb{Z}[G]$ –module on the meridian of A , which gets mapped to the longitude in $S^3 \setminus \nu C$ which is zero in $H_1(S^3 \setminus \nu C; \mathbb{Z}[\mathbb{Z}])$. From the above commutative diagram it now follows that

$$H_1(M_S; \mathbb{Z}[G]) \cong H_1(M_K; \mathbb{Z}[G]) \oplus H_1(S^3 \setminus \nu C; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G]$$

since $H_1(S^3 \setminus \nu C; \mathbb{Z}[G]) \cong H_1(S^3 \setminus \nu C; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G]$. The lemma now follows from $H_1(S^3 \setminus \nu C; \mathbb{Z}[\mathbb{Z}]) \cong H_1(M_C; \mathbb{Z}[\mathbb{Z}])$. □

7 Examples: Satellite knots of 6_1

In Figure 7.1 we see three projections of the knot 6_1 , the first one having the minimal crossing number 6. Indeed, the isotopy between K_1 and K_3 is shown in [2]. The isotopy between K_2 and K_3 follows from Figures 1.1 and 7.2, which shows that both knots are formed by band connected sum of two trivial knots

Figure 7.1: Three projections of the knot 6_1

Figure 7.2: A ribbon disk for 6_1

along isotopic bands. Note that the two trivial circles in Figure 7.2 bound disjoint disks in S^2 . Now consider the knot 6_1 with the Seifert surface F in Figure 7.3. With the given basis a, b for $H_1(F)$ we get

$$A(6_1) = \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}$$

which then shows that $\Delta_{6_1}(t) = \det(At - A^t) = (t - 2)(t^{-1} - 2)$.

Figure 7.3: Seifert surface for 6_1

Examples of h-ribbon knots

We first prove a general result. Let R be a ribbon knot with ribbon disk D_R , such that $\pi_1(D^4 \setminus D_R) \cong SR$. Denote the induced map $\pi_1(M_K) \rightarrow G := SR$ by φ . Let C be any knot and $A \subset S^3 \setminus K$ the unknot in S^3 .

Proposition 7.4 *If $\varphi(A) = e$ then the satellite knot $S = S(R, C, A)$ is h-ribbon.*

Proof By Lemma 6.2 there exists a map $\pi_1(M_S) \rightarrow G$ with $H_*(M_S; \mathbb{Z}[G]) \cong H_*(M_R; \mathbb{Z}[G])$. From Theorem 1.3 it follows that $\text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_R; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$ and hence (M_S, φ) also satisfies $\text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_S; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$. The proposition is implied by Theorem 1.3. \square

This result is similar to the well-known fact that the Whitehead double of any knot (which is the satellite of the unknot) is topologically slice. This is an immediate corollary from Freedman's slicing theorem and Lemma 6.2.

Now turn back to the study of $K = 6_1$. From the discussion in Section 2 we know that K has a ribbon disk D such that $\pi_1(N_D) \cong \langle a, b \mid a^{-1}ba^{-1}bab^{-1} \rangle = SR$. The group $\pi_1(M_K) \cong \pi_1(S^3 \setminus K)/\langle \text{longitude} \rangle$ is generated by the meridians of K_3 . From Figure 2.3 it follows that the map

$$\varphi: \pi_1(M_K) \rightarrow \pi_1(N_D) \cong \langle a, b \mid a^{-1}ba^{-1}bab^{-1} \rangle = G$$

is given by the map indicated in Figure 7.5. The image of the other meridians

Figure 7.5: The map $\pi_1(S^3 \setminus K) \rightarrow \langle a, b \mid a^{-1}ba^{-1}bab^{-1} \rangle$

is determined by the image of the two given meridians.

As an example take $K = 6_1$, A as in Figure 7.6 and C the trefoil knot. We

Figure 7.6: Ribbon knot with choice of A and the satellite knot $S(6_1, \text{trefoil}, A)$

have $\varphi(A) = e \in G$ as one can easily verify. Therefore S is h-ribbon by Proposition 7.4. But in fact S is trivially ribbon already, since the ribbon disk of 6_1 ‘survives’ the satellite construction. We therefore need a more subtle choice of A . Now consider Figure 1.5. One can easily verify that $\varphi(A) = e$. The knot 6_1 as a knot in the torus $S^3 \setminus \nu A$ is given in Figure 1.5 on the right. Wrapping this knot around say the trefoil gives a h-ribbon knot, which we conjecture not to be smoothly ribbon.

Remark It follows immediately from arguments as in Lemma 6.2 that

$$(H_1(M_K; \mathbb{Z}[\mathbb{Z}]), Bl(\mathbb{Z})) \cong (H_1(M_S; \mathbb{Z}[\mathbb{Z}]), Bl(\mathbb{Z})).$$

In particular K and S have the same abelian invariants. Livingston [21] showed that there exists a knot \tilde{K} with

$$(H_1(M_K; \mathbb{Z}[\mathbb{Z}]), Bl(\mathbb{Z})) \cong (H_1(M_{\tilde{K}}; \mathbb{Z}[\mathbb{Z}]), Bl(\mathbb{Z}))$$

which is not topologically slice (cf also [18]). This shows that the vanishing of $Bl(SR)$, which is a condition on the non-commutative homology of K , can not be reduced to a condition on abelian invariants.

Non-existence of certain ribbon disks

Now consider the knot 6_1 with the Seifert surface F in Figure 7.3. For given knots C_α, C_β consider $S(K, C_\alpha, C_\beta, \alpha, \beta)$, ie, the result of applying the satellite construction twice. This means that we tie knots C_α and C_β into the bands α and β .

Proposition 7.7 *If $\Delta_{C_\alpha}(t) \neq 1, \Delta_{C_\beta}(t) \neq 1$, then S has no h-ribbon with fundamental group SR .*

Proof Assume that S has in fact a h-ribbon D with fundamental group $G := SR = \mathbb{Z} \ltimes \Lambda / (t-2)$. Then $\text{Ker}\{H_1(M_S; \mathbb{Z}[\mathbb{Z}]) \rightarrow H_1(N_D; \mathbb{Z}[\mathbb{Z}])\}$ is a metabolizer for $B\ell(\mathbb{Z})$ (cf [12]). In the following we will write $\Lambda := \mathbb{Z}[t, t^{-1}] \cong \mathbb{Z}[\mathbb{Z}]$. Note that α, β in Figure 7.3 lift to elements $\tilde{\alpha}, \tilde{\beta}$ in $H_1(M_K; \Lambda)$, in fact

$$H_1(M_K; \Lambda) \cong (\Lambda\tilde{\alpha} \oplus \Lambda\tilde{\beta}) / (At - A^t) \cong \Lambda\tilde{\alpha} / (2t - 1) \oplus \Lambda\tilde{\beta} / (t - 2).$$

Furthermore the Blanchfield pairing $B\ell(\mathbb{Z})$ is given by the matrix $(t - 1)(At - A^t)^{-1}$. It is easy to see that the submodule generated by $\tilde{\alpha}$ respectively by $\tilde{\beta}$ are the only two metabolizers for $B\ell(\mathbb{Z})$. In particular the map $\pi := \pi_1(M_S) \rightarrow \pi_1(N_D)$ is up to automorphism of G either of the form

$$\varphi_\alpha: \pi_1(M_S) \rightarrow \pi / \pi^{(2)} \cong \mathbb{Z} \ltimes H_1(M_S; \Lambda) \rightarrow \mathbb{Z} \ltimes \Lambda\tilde{\alpha} / (2t - 1) \rightarrow SR$$

or it is of the same form with $\tilde{\alpha}$ replaced by $\tilde{\beta}$. We denote this homomorphism by φ_β . By Theorem 1.3 we get $\text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_S; \mathbb{Z}[G]), \mathbb{Z}[G]) = 0$ with G -coefficients induced by φ_α or by φ_β . Now consider coefficients induced by φ_α . From Lemma 6.2 it follows that

$$H_1(M_S; \mathbb{Z}[G]) \cong H_1(M_K; \mathbb{Z}[G]) \oplus H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G].$$

We compute

$$\begin{aligned} & \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_S; \mathbb{Z}[G]), \mathbb{Z}[G]) \\ & \cong \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) \oplus H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G], \mathbb{Z}[G]) \\ & \cong \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) \oplus \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]) \otimes_{\mathbb{Z}[\mathbb{Z}]} \mathbb{Z}[G], \mathbb{Z}[G]) \\ & \cong \text{Ext}_{\mathbb{Z}[G]}^1(H_1(M_K; \mathbb{Z}[G]), \mathbb{Z}[G]) \oplus \text{Ext}_{\mathbb{Z}[\mathbb{Z}]}^1(H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]), \mathbb{Z}[\mathbb{Z}]) \\ & \cong \text{Ext}_{\mathbb{Z}[\mathbb{Z}]}^1(H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]), \mathbb{Z}[\mathbb{Z}]). \end{aligned}$$

Note that $H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]) \cong H_1(S^3 \setminus C_\alpha; \mathbb{Z}[\mathbb{Z}])$, in particular it is \mathbb{Z} -torsion free. It follows from [20, Theorem 3.4] that $\text{Ext}_{\mathbb{Z}[\mathbb{Z}]}^1(H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}]), \mathbb{Z}[\mathbb{Z}]) \cong H_1(M_{C_\alpha}; \mathbb{Z}[\mathbb{Z}])$, which is non-trivial since $\Delta_{C_\alpha}(t) \neq 1$. The same calculation for φ_β then gives the contradiction. \square

Non-uniqueness of ribbon groups

A ribbon knot can in general have ribbons with non-isomorphic groups. For example let K be a non-trivial knot with $\Delta_K(t) = 1$, eg, the Whitehead double of a non-trivial knot. Let $G := \pi_1(S^3 \setminus K)$, then G is in particular a ribbon group for the knot $L := K \# -K$. On the other hand, L still has trivial Alexander polynomial and so by Theorem 1.3 it follows that L also has a h-ribbon with fundamental group \mathbb{Z} . In fact, if K is the Whitehead double of a ribbon knot then it is ribbon, not just h-ribbon, with fundamental group \mathbb{Z} (and so is L).
