Product formulae for Ozsváth–Szabó 4–manifold invariants

STANISLAV JABUKA
THOMAS E MARK

We give formulae for the Ozsváth–Szabó invariants of 4–manifolds \(X\) obtained by fiber sum of two manifolds \(M_1, M_2\) along surfaces \(\Sigma_1, \Sigma_2\) having trivial normal bundle and genus \(g \geq 1\). The formulae follow from a general theorem on the Ozsváth–Szabó invariants of the result of gluing two 4–manifolds along a common boundary, which is phrased in terms of relative invariants of the pieces. These relative invariants take values in a version of Heegaard Floer homology with coefficients in modules over certain Novikov rings; the fiber sum formula follows from the theorem that this "perturbed" version of Heegaard Floer theory recovers the usual Ozsváth–Szabó invariants, when the 4–manifold in question has \(b^+ \geq 2\). The construction allows an extension of the definition of Ozsváth–Szabó invariants to 4–manifolds having \(b^+ = 1\) depending on certain choices, in close analogy with Seiberg–Witten theory. The product formulae lead quickly to calculations of the Ozsváth–Szabó invariants of various 4–manifolds; in all cases the results are in accord with the conjectured equivalence between Ozsváth–Szabó and Seiberg–Witten invariants.

1 Introduction

At the time of writing, there is no example of a smoothable topological 4–manifold whose smooth structures have been classified. Indeed, no smooth 4–manifold is known to support only finitely many smooth structures, and in virtually every case a 4–manifold that admits more than one smooth structure is known to admit infinitely many such structures. A substantial amount of ingenuity by a large number of authors—see Stern [19] for a brief survey—has been required to produce these exotic 4–manifolds, though ultimately the list of topological tools used in the constructions is perhaps surprisingly short. The standard approach to distinguishing smooth structures on 4–manifolds has been to make use of gauge-theoretic invariants, which requires an understanding of how these invariants behave under the cut-and-paste operations used in constructing examples. In the case of the Seiberg–Witten invariants, this understanding was provided by Morgan–Mrowka–Szabó [7], Morgan–Szabó–Taubes [8], D Park [17], Li–Liu [5] and many others, and the Seiberg–Witten invariants have become the tool...
of choice for studying smooth manifolds. Beginning in 2000, Ozsváth and Szabó [12; 11; 15] introduced invariants of 3– and 4–dimensional manifolds meant to mimic the Seiberg–Witten invariants but also avoid the technical issues that for many years prevented the expected Seiberg–Witten–Floer theory from taking shape. Their theory has been remarkably successful and has had a number of important consequences in the study of 3–manifolds and knot theory. The 4–dimensional side of the story has been developed to a somewhat lesser extent, however, and the existing gauge-theoretic technology means it is still the case that Seiberg–Witten invariants are often the easiest to use in the study of smooth 4–manifolds. Our aim here is to develop reasonably general cut-and-paste principles for Ozsváth–Szabó invariants, that will be useful in a variety of situations. A central tool in many constructions of exotic 4–manifolds is the normal connected sum or “fiber sum,” in which neighborhoods of diffeomorphic surfaces are excised from closed 4–manifolds and the resulting complements glued together along their boundary. As an application of the formalism we introduce here, and as a motivating test case, we give formulae that essentially determine the behavior of the Ozsváth–Szabó 4–manifold invariants under fiber sum along surfaces of trivial normal bundle.

To realize this goal we are obliged to introduce a substantial amount of machinery, including the development of Heegaard Floer homology with coefficients in certain power series (Novikov) rings. This can be viewed in analogy with Seiberg–Witten Floer homology perturbed by a 2–dimensional cohomology class, and in many ways exhibits parallel behavior. It is our hope that this “perturbed” Heegaard Floer theory will be of interest in other applications as well.

For the sake of exposition, we state our results in this introduction in order of increasing technicality. In particular, Ozsváth and Szabó defined their invariants initially for 4–manifolds $M$ with $b^+ (M) \geq 2$, and since the theory is simplest in that case we begin there.

1.1 Constructions and statements of results when $b^+ \geq 2$

The Ozsváth–Szabó invariants [15; 9] are defined using a “TQFT” construction, meaning that they are built from invariants of 3–dimensional manifolds (the Heegaard Floer homology groups) and cobordisms between such manifolds. To a closed oriented 4–manifold $M$ with $b^+ (M) \geq 2$, with a spin$^c$ structure $s$, Ozsváth and Szabó associate a linear function

$$\Phi_{M,s} : A(M) \to \mathbb{Z},$$

where $A(M)$ is the algebra $\Lambda^* (H_1 (M; \mathbb{Z})/\text{torsion}) \otimes \mathbb{Z}[U]$, graded such that elements of $H_1 (M)$ have degree 1 and $U$ has degree 2. This invariant has the property that
\( \Phi_{M,s} \) is nonzero for at most finitely many spin\(^c\) structures \( s \), and furthermore, with \( s \) fixed, vanishes on all elements of \( \mathbb{A}(M) \) not having degree

\[ d(s) = \frac{1}{4}(c_1^2(s) - 3\sigma(M) - 2e(M)), \]

where \( \sigma \) denotes the signature of the intersection form on \( M \) and \( e \) is the Euler characteristic. Ozsváth and Szabó conjecture [15] that \( \hat{\mathbb{A}}(M) \) is identical with the Seiberg–Witten invariant.

We remark that there is a sign ambiguity in the definition of \( \hat{\mathbb{A}}(M) \), so that the results to follow are true up to an overall sign.

The fiber sum of two smooth 4–manifolds is defined as follows. Let \( M_1 \) and \( M_2 \) be closed oriented 4–manifolds, and suppose \( \Sigma_i \hookrightarrow M_i, i = 1, 2 \), are smoothly embedded closed oriented surfaces of the same genus \( g \). We assume throughout this paper that \( g \) is at least 1 and that the \( \Sigma_i \) have trivial normal bundles. In this case, \( \Sigma_i \) has a neighborhood \( N(\Sigma_i) \) diffeomorphic to \( \Sigma_i \times D^2 \). Choose an orientation-preserving diffeomorphism \( f: \Sigma_1 \to \Sigma_2 \), and lift it to an orientation-reversing diffeomorphism \( \phi: \partial N(\Sigma_1) \to \partial N(\Sigma_2) \) via conjugation in the normal fiber. We define the fiber sum \( X = M_1 \#_\Sigma M_2 \) by

\[ X = (M_1 \setminus N(\Sigma_1)) \cup_\phi (M_2 \setminus N(\Sigma_2)) \]

In general, the manifold \( X \) can depend on the choice of \( \phi \). We assume henceforth that the homology classes \( [\Sigma_1] \) and \( [\Sigma_2] \) are nontorsion elements of \( H_2(M; \mathbb{Z}) \) (though the results of this paper can in principle be adapted to other situations).

To state the results, it is convenient to express the Ozsváth–Szabó invariant in terms of the group ring \( \mathbb{Z}[H^2(M; \mathbb{Z})] \). That is to say, we write

\[ \text{OS}_M = \sum_{s \in \text{Spin}^c(M)} \Phi_{M,s} e^{c_1(s)}, \]

where \( e^{c_1(s)} \) is the formal variable in the group ring corresponding to the first Chern class of the spin\(^c\) structure \( s \) (note that \( c_1(s) = c_1(s') \) for distinct spin\(^c\) structures \( s \) and \( s' \) if and only if \( s - s' \) is of order 2 in \( H^2(M; \mathbb{Z}) \), so the above formulation may lose some information if 2–torsion is present). The coefficients of the above expression are functions on \( \mathbb{A}(M) \), so that \( \text{OS}_M \) is an element of \( \mathbb{Z}[H^2(M; \mathbb{Z})] \otimes \mathbb{A}(M)^* \). The value of the invariant on \( \alpha \in \mathbb{A}(M) \) is denoted \( \text{OS}_M(\alpha) \in \mathbb{Z}[H^2(M; \mathbb{Z})] \).

The behavior of \( \Phi_{M,s} \) under fiber sum depends on the value of \( \langle c_1(s), [\Sigma] \rangle \) (since \( c_1(s) \) is a characteristic class, this value is always even when \( [\Sigma]^2 = 0 \)). Thus, we
partition $\text{OS}_M$ accordingly: for an embedded surface $\Sigma \hookrightarrow M$ with trivial normal bundle, let
\[ \text{OS}^k_M = \sum_{\langle c_1(s), [\Sigma] \rangle = 2k} \Phi_{M,s} e^{c_1(s)}. \]
The adjunction inequality for Ozsváth–Szabó invariants implies that $\text{OS}^k_M \equiv 0$ if $|k| > g - 1$.

The topology of fiber sums is complicated in general by the presence of rim tori. A rim torus is a submanifold of the form $\gamma \times S^1 \subset \Sigma \times S^1$, where $\gamma$ is an embedded circle on $\Sigma$. Such tori are homologically trivial in the fiber summands $M_i$, but typically essential in $X = M_1 \#_\Sigma M_2$. Let $\mathcal{R}$ denote the subspace of $H^2(X; \mathbb{Z})$ spanned by the Poincaré duals of rim tori, and let $\rho: H^2(X; \mathbb{Z}) \to H^2(X; \mathbb{Z})/\mathcal{R}$ denote the natural projection. If $b_i \in H^2(M_i; \mathbb{Z})$, $i = 1, 2$, are cohomology classes with the property that $b_1|_{\partial N(\Sigma_1)}$ agrees with $b_2|_{\partial N(\Sigma_2)}$ under $\phi$, then Mayer–Vietoris arguments show that there exists a class $b \in H^2(X; \mathbb{Z})$ whose restrictions to $M_i \setminus N(\Sigma_i)$ agrees with the corresponding restrictions of $b_i$, and furthermore that $b$ is determined uniquely up to elements of $\mathcal{R}$ and multiples of the Poincaré dual of $\Sigma$. If $b$, $b_1$ and $b_2$ satisfy these conditions on their respective restrictions, we say that the three classes are compatible with the fiber sum. We can eliminate part of the ambiguity in $b$ given $(b_1, b_2)$ by requiring that
\[ b^2 = b_1^2 + b_2^2 + 4|m|, \]
where $m = \langle b_1, [\Sigma_1] \rangle = \langle b_2, [\Sigma_2] \rangle$. With this convention, the pair $(b_1, b_2)$ gives rise to a well-defined element of $H^2(X; \mathbb{Z})/\mathcal{R}$ (see Section 10.3 for details).

**Theorem 1.1** Let $X = M_1 \#_\Sigma M_2$ be obtained by fiber sum along a surface $\Sigma$ of genus $g > 1$ from manifolds $M_1$, $M_2$ satisfying $b^+(M_i) \geq 2$, $i = 1, 2$. If $|k| > g - 1$ then $\text{OS}^k_X = \text{OS}^k_{M_1} = \text{OS}^k_{M_2} = 0$. In general, we have
\[ \rho \left( \text{OS}^k_X(\alpha) \right) = \sum_{\beta \in B_k} \text{OS}^k_{M_1}(\alpha_1 \otimes \beta) \cdot \text{OS}^k_{M_2}(f_* (\beta^\circ) \otimes \alpha_2) \cdot u_{\beta,k} \]
where $\alpha_i \in \mathcal{A}(M_i \setminus N(\Sigma_i))$ are any elements such that $\alpha_1 \otimes \alpha_2$ maps to $\alpha$ under the inclusion-induced homomorphism.

The notation of the theorem requires some explanation. First, the product of group ring elements appearing on the right makes use of the construction outlined above, producing elements of $H^2(X; \mathbb{Z})/\mathcal{R}$ from compatible pairs $(b_1, b_2)$. The set $B_k$ denotes a basis over $\mathbb{Z}$ for the group $H_* (\text{Sym}^d (\Sigma); \mathbb{Z}) \cong \bigoplus_{i=0}^d \Lambda^i H_1(\Sigma) \otimes \mathbb{Z}[U]/U^{d-i+1}$, thought...
of as a subgroup of $\Lambda(\Sigma)$, where $d = g - 1 - |k|$. Likewise, $\{\beta^\circ\}$ denotes the dual basis to $B_k$ under a certain nondegenerate pairing (see Section 10.3). The terms $\alpha_1 \otimes \beta$ and $f_*(\beta^\circ) \otimes \alpha_2$ are understood to mean the images of those elements in $\Lambda(M_1)$ and $\Lambda(M_2)$, using the inclusion-induced maps. Finally, $\phi_{\beta,k}$ is a polynomial in the variable $e^{\text{PD}[\Sigma]}$ whose constant coefficient is 1, and which is equal to 1 except possibly in the case $k = 0$.

The left hand side of (1) lies in the group ring of $H^2(X; \mathbb{Z})/\mathcal{R}$, and its coefficients are “rim torus averaged” Ozsváth–Szabó invariants. That is to say, each coefficient of $\rho(\text{OS}_k^X)$ is a term of the form

$$\Phi_{\text{Rim}}^{X,s} = \sum_{s' \in \text{Spin}^c(X)} \Phi_{X,s'}.$$

A 4–manifold $X$ is said to have (Ozsváth–Szabó) simple type if any spin$^c$ structure $s$ for which $\Phi_{X,s} \neq 0$ has $d(s) = 0$. We have:

**Corollary 1.2** If $M_1$ and $M_2$ have simple type, then the fiber sum $X = M_1#_\Sigma M_2$ has the property that if $\Phi_{\text{Rim}}^{X,s} = 0$ whenever $d(s) \neq 0$. Furthermore,

(2) \[
\rho(\text{OS}_k^X) = 0 \quad \text{if } |k| < g - 1, \\
\rho(\text{OS}_{X}^{\pm(g-1)}(\alpha)) = \begin{cases} 
\text{OS}_{M_1}^{\pm(g-1)}(1) \cdot \text{OS}_{M_2}^{\pm(g-1)}(1) & \text{if } \alpha = 1 \\
0 & \text{if } \deg(\alpha) > 1.
\end{cases}
\]

In other words, the fiber sum of manifolds of simple type has simple type after sum over rim tori. We note that Equation (2) holds if $M_1$ and $M_2$ are assumed only to have $\Lambda(\Sigma)$–simple type, that is, if $\Phi_{M,s}(\alpha) = 0$ whenever $\alpha$ lies in the ideal of $\Lambda(M)$ generated by $U$ and the image of $H_1(\Sigma)$.

We should remark that Taubes [20] has shown that symplectic 4–manifolds with $b^+ \geq 2$ have Seiberg–Witten simple type. It seems safe, therefore, to conjecture the following:

**Conjecture 1.3** If $X$ is a symplectic 4–manifold with $b^+(X) \geq 2$ then $X$ has Ozsváth–Szabó simple type.

Leaving this issue for now, we turn to the case of a fiber sum along a torus, where the product formula is slightly different.
Theorem 1.4 Let $X = M_1 \#_\Sigma M_2$ be obtained by fiber sum along a surface $\Sigma$ of genus $g = 1$, such that $M_1$, $M_2$, and $X$ each have $b^+ \geq 2$. Let $\tilde{T}$ denote the Poincaré dual of the class in $H_2(X; \mathbb{Z})$ induced by $[\Sigma_1]$, and write $T$ for the image of $\tilde{T}$ in $H^2(X; \mathbb{Z})/\mathbb{R}$. Then for any $\alpha \in \Lambda(X)$ we have
\[
\rho(\mathrm{OS}_X(\alpha)) = (T - T^{-1})^2 \cdot \mathrm{OS}_{M_1}(\alpha_1) \cdot \mathrm{OS}_{M_2}(\alpha_2)
\]
where $\alpha_1 \otimes \alpha_2 \in \Lambda(M_1) \otimes \Lambda(M_2)$ maps to $\alpha$ as before.

Here the product between $\mathrm{OS}_{M_1}$ and $\mathrm{OS}_{M_2}$ uses the previous construction, while multiplication with $T$ takes place in the group ring of $H^2(X; \mathbb{Z})/\mathbb{R}$.

We will show (Proposition 11.1) that any 4–manifold $M$ containing an essential torus $T$ of self-intersection 0 has $\Lambda(T)$–simple type, in analogy with a result of Morgan, Mrowka, and Szabó in Seiberg–Witten theory [7].

It is interesting to compare these results with those in Seiberg–Witten theory. Taubes proved an analogue of Theorem 1.4 in [21], generalizing work of Morgan–Mrowka–Szabó [7], and D Park [17] gave an independent proof of that result. The higher-genus case was considered by Morgan, Szabó and Taubes [8], but only under the condition that $|k| = g - 1$. In this case the sum appearing in Theorem 1.1 is trivial since $B_{g-1} = \{1\}$, and the result here gives a product formula directly analogous to that of [8]. To our knowledge, no product formulae at the level of generality of Theorem 1.1 have yet appeared in the literature on Seiberg–Witten theory.

1.2 Relative invariants and a general gluing result

The theorems above are proved as particular cases of a general result on the Ozsváth–Szabó invariants of 4–manifolds obtained by gluing two manifolds along their boundary. In its most general form, the form that is useful in the context of fiber sums (Theorem 1.6 below), the statement involves perturbed Heegaard Floer invariants. If one is interested in gluing two manifolds-with-boundary that both have $b^+ \geq 1$, however, the perturbed theory is unnecessary and there is a slightly simpler “intermediate” result. To state it, recall that the construction of the 4–manifold invariant $\Phi_{M,s}$ is based on the Heegaard Floer homology groups associated to closed spin$^c$ 3–manifolds $(Y, s)$. These groups have various incarnations; the relevant one for our immediate purpose is denoted $HF_{\text{red}}(Y, s)$. Below, we recall the construction of Heegaard Floer homology with “twisted” coefficients, whereby homology groups are obtained whose coefficients are modules $M$ over the group ring $R_Y = \mathbb{Z}[H^1(Y)]$ (here and below, ordinary (co)homology is considered with integer coefficients). If $Y = \partial Z$ is the boundary of an oriented 4–manifold $Z$, then such a module is provided by
\[
M_Z = \mathbb{Z}[\ker(H^2(Z, \partial Z) \rightarrow H^2(Z))],
\]
where \( H^1(Y) \) acts by the coboundary homomorphism \( H^1(Y) \to H^2(Z, \partial Z) \). The intermediate product formula alluded to above can be formulated as follows.

**Theorem 1.5** If \((Z, s)\) is a spin\(^c\) \(-\)manifold with connected spin\(^c\) boundary \((Y, s_Y)\) and if \(b^+(Z) \geq 1\), then there exists a relative Ozsváth–Szabó invariant \( \Psi_{Z, s} \) which is a function

\[
\Psi_{Z, s}: \mathcal{A}(Z) \to HF_{\text{red}}(Y, s_Y; M_Z),
\]

a diffeomorphism invariant of \((Z, s)\) well-defined up to multiplication by a unit in \(\mathbb{Z}[H^1(Y)]\).

Furthermore, if \((Z_1, s_1)\) and \((Z_2, s_2)\) are two such spin\(^c\) \(-\)manifolds with spin\(^c\) boundary \(\partial Z_1 = (Y, s) = -\partial Z_2\), write \(X = Z_1 \cup_Y Z_2\). Then there exists an \(R_Y\)–sesquilinear pairing

\[
(\cdot, \cdot): HF_{\text{red}}(Y, s; M_{Z_1}) \otimes_{R_Y} HF_{\text{red}}(-Y, s; M_{Z_2}) \to M_{X,Y},
\]

where \(M_{X,Y} = \mathbb{Z}[K(X,Y)]\) and \(K(X,Y) = \ker(H^2(X) \to H^2(Z_1) \oplus H^2(Z_2))\). The pairing has the property that for any spin\(^c\) structure \(s\) on \(X\) restricting to \(s_i\) on \(Z_i\), we have an equality of group ring elements:

\[
\sum_{h \in K(X,Y)} \Phi_{X,s+h}(\alpha) e^h = (\Psi_{Z_1, s_1}(\alpha_1), \Psi_{Z_2, s_2}(\alpha_2)),
\]

up to multiplication by a unit in \(\mathbb{Z}[K(X,Y)]\). Here \(\alpha \in \mathcal{A}(X)\), \(\alpha_1 \in \mathcal{A}(Z_1)\) and \(\alpha_2 \in \mathcal{A}(Z_2)\) are related by inclusion-induced multiplication as before.

To understand the term “\(R_Y\)–sesquilinear,” observe that \(R_Y = \mathbb{Z}[H^1(Y)]\) is equipped with an involution \(r \mapsto \bar{r}\) induced by \(h \mapsto -h\) in \(H^1(Y)\). To say that the pairing in the theorem is sesquilinear means that

\[
(g\xi, \eta) = g(\xi, \eta) = (\xi, g\eta)
\]

for \(g \in R_Y\), \(\xi \in HF_{\text{red}}(Y, s; M_{Z_1})\) and \(\eta \in HF_{\text{red}}(-Y, s; M_{Z_2})\).

We note that the reason for the assumption \(b^+(Z) \geq 1\) in the theorem above is that this condition guarantees that the homomorphism in \(HF^-\) induced by \(Z \setminus B^4\) (which gives rise to the relative invariant \(\Psi_{Z, s}\) above) takes values in the reduced Floer homology \(HF_{\text{red}}(Y, s; M_{Z_1}) \subset HF^-(Y, s; M_Z)\). That fact in turn is necessary to make sense of the pairing \((\cdot, \cdot)\). In the notation of later sections, \((\cdot, \cdot) = (\tau^{-1}(.), \cdot)\) where \(\tau: HF^+ \to HF^-\) is the natural map; \(\tau\) is invertible only on the reduced groups.

The utility of Theorem 1.5 is limited somewhat by the difficulty of determining the relative invariants \(\Psi_{Z, s}\) in general. Furthermore, in the case of a fiber sum it is natural
to hope to relate the relative invariants of the complement of the neighborhood \( \Sigma \times D^2 \) of the summing surface in \( M \) to the absolute invariants of \( M \); however the manifold \( \Sigma \times D^2 \) has \( b^+ = 0 \) and it is not clear that the relative invariant is well-defined. This issue is addressed by the introduction of a “perturbation.”

1.3 Perturbed Heegaard Floer theory and results when \( b^+ \geq 1 \)

Let \( Y \) be a closed oriented 3–manifold and \( \eta \in H^2(Y; \mathbb{R}) \) a given cohomology class. The Novikov ring associated to \( \eta \) is the set of formal series

\[
\mathcal{R}_{Y, \eta} = \left\{ \sum_{g \in H^1(Y; \mathbb{Z})} a_g \cdot g \mid a_g \in \mathbb{Z} \right\} \subset \mathbb{Z}[[H^1(Y; \mathbb{Z})]]
\]

subject to the condition that for each \( N \in \mathbb{Z} \), the set of \( g \in H^1(Y; \mathbb{Z}) \) with \( a_g \) nonzero and \( (g \cup \eta, [Y]) < N \) is finite. This means \( \mathcal{R}_{Y, \eta} \) consists of “semi-infinite” series with variables in \( H^1(Y; \mathbb{Z}) \), with the usual convolution product.

In Section 8 below, we develop the theory of Heegaard Floer homology for 3–manifolds \( Y \) and 4–dimensional cobordisms \( W \) equipped with 2–dimensional cohomology classes \( \eta \), having coefficients in a module \( \mathcal{M}_\eta \) over \( \mathcal{R}_{Y, \eta} \). We refer to this theory as Heegaard Floer homology perturbed by \( \eta \). Many features of the unperturbed theory carry over to this setting with minimal modification, but one key simplification is that if \( \eta \) is chosen “generically” in a suitable sense (in particular \( \eta \neq 0 \)), then \( HF^\infty(Y, s; \mathcal{M}_\eta) = 0 \) for any \( \mathcal{R}_{Y, \eta} \)–module \( \mathcal{M}_\eta \). In fact, one can arrange this latter fact to hold for any nonzero perturbation \( \eta \) by a further extension of coefficients: Heegaard Floer homology is naturally a module over a polynomial ring \( \mathbb{Z}[U] \), and we form a “\( U \)–completion” by extension to the power series ring \( \mathbb{Z}[[U]] \). The \( U \)–completed Floer homology is written \( HF_\bullet(Y, s; \mathcal{M}_\eta) \) by notational analogy with a similar construction in monopole Floer homology (see Kronheimer and Mrowka [4]). The vanishing of \( HF^\infty_\bullet(Y, s; \mathcal{M}_\eta) \) means that \( HF^-_\bullet(Y, s; \mathcal{M}_\eta) = HF^-_\text{red}(Y, s; \mathcal{M}_\eta) \) for all such \( \mathcal{M}_\eta \), and allows us to define a relative invariant

\[
\Psi_{Z, s, \eta} \in HF^-_\text{red}(Y, s; \mathcal{M}_{Z, \eta})
\]

that has the desired properties so long as \( \eta|_Y \neq 0 \). Note, however, that \( \Psi_{Z, s, \eta} \) is defined only up to sign and multiplication by an element of \( H^1(Y) \). We remark that if \( \eta|_Y = 0 \) then \( \mathcal{R}_{Y, \eta} = \mathcal{R}_Y \), and we recover the unperturbed theory.

Now suppose that \( X \) is a closed 4–manifold, \( Y \subset X \) a separating submanifold, and \( \eta \in H^2(X; \mathbb{R}) \) a cohomology class such that either \( \eta|_Y \neq 0 \), or in the decomposition \( X = Z_1 \cup_Y Z_2 \) we have \( b^+(Z_i) \geq 1 \). (Such a submanifold \( Y \) is said to be an allowable

cut for \( \eta \).) Then we can define the perturbed Ozsváth–Szabó invariant associated to \( X, Y, \eta, s \) and a spin\(^c\) structure \( s \) to be

\[
\Phi_{X,Y,\eta,s}(\alpha) = \langle \tau^{-1}(\Psi_{Z_1,\eta,s}(\alpha_1)), \Psi_{Z_2,\eta,s}(\alpha_2) \rangle.
\]

This invariant takes values in a module \( \mathcal{M}_{X,Y,\eta} \), which is a suitable Novikov completion of \( M_{X,Y} \) introduced previously. In Section 8 we show (Theorem 8.17) that if \( b^+(X) \geq 2 \) then \( \Phi_{X,Y,\eta,s} \) is in fact a polynomial lying in \( M_{X,Y} \), whose coefficients are the Ozsváth–Szabó invariants of \( X \) in the various spin\(^c\) structures having restrictions to \( Z_1 \) and \( Z_2 \) that agree with the restrictions of \( s \). The precise statement is the following:

**Theorem 1.6** Let \( X \) be a closed oriented 4–manifold with \( b^+(X) \geq 2 \), and \( Y \subset X \) a connected submanifold determining a decomposition \( X = Z_1 \cup_Y Z_2 \), where \( Z_i \) are 4–manifolds with boundary. Fix a class \( \eta \in H^2(X; \mathbb{R}) \), and assume that \( Y \) is an allowable cut for \( \eta \). If \( b^+(Z_1) \) and \( b^+(Z_2) \) are not both 0, then for any spin\(^c\) structure \( s \) on \( X \) and element \( \alpha \in \mathbb{A}(X) \),

\[
\sum_{t \in K(X,Y)} \Phi_{X,s+\tau}e^t = \Phi_{X,Y,\eta,s}(\alpha) = \langle \tau^{-1}\Psi_{Z_1,\eta,s}(\alpha_1), \Psi_{Z_2,\eta,s}(\alpha_2) \rangle
\]

up to sign and multiplication by an element of \( K(X,Y) \), where \( \alpha_1 \otimes \alpha_2 \mapsto \alpha \) as before. If \( b^+(Z_1) = b^+(Z_2) = 0 \) then the same is true after possibly replacing \( \eta \) by another class \( \tilde{\eta} \), where \( \tilde{\eta}|_{Z_i} = \eta|_{Z_i} \) for \( i = 1, 2 \).

The above definition (3) of \( \Phi_{X,Y,\eta,s} \) makes sense for any allowable pair \( (Y, \eta) \) and spin\(^c\) structure \( s \), but its dependence on the choice of \( (Y, \eta) \) is not clear. When \( b^+(X) \geq 2 \) it follows from Theorem 1.6 that since \( \Phi_{X,s} \) is independent of \( Y \) and \( \eta \), so is \( \Phi_{X,Y,\eta,s} \). However when \( b^+(X) = 1 \) the situation is not so simple; indeed, different choices of \( (Y, \eta) \) for a given \( (X, s) \) can lead to different results. This situation is analogous to the chamber structure of Seiberg–Witten invariants for 4–manifolds with \( b^+ = 1 \); partial results in this direction are given in Section 8.

Note that the existence of a separating 3–manifold \( Y \subset X \) and a class \( \eta \in H^2(X, \mathbb{R}) \) restricting nontrivially to \( Y \) implies that \( X \) is indefinite, in particular \( b^+(X) \geq 1 \).

We also point out a minor difference between Theorem 1.1 and Theorem 1.4 from the first section, and Theorem 1.6 above and Theorem 1.8 and Theorem 1.9 below. In the former results, the various spin\(^c\) structures are labeled by their Chern classes, while in the latter they are identified in an affine way with two-dimensional cohomology classes. Thus the results in the present situation do not lose information corresponding to classes whose difference is of order 2, and to translate from results in this subsection to those in the first one we must square the variables.
An immediate consequence of Theorem 1.6 is the following result on the Ozsváth–Szabó invariants of a manifold obtained by gluing two 4–manifolds along a boundary 3–torus. To state it, note first that if $Z$ is a 4–manifold with boundary diffeomorphic to $T^3$ and $\eta \in H^2(Z; \mathbb{R})$ is a class whose restriction to $T^3$ is nontrivial then the relative invariant $\Psi_{Z, s, \eta}$ is well-defined, and takes values in the ring $K(Z, \eta) \subset \mathbb{Z}[[K(Z)]]$, where $K(Z) = \ker(H^2(Z, \partial Z) \to H^2(Z))$ and $K(Z, \eta)$ is a Novikov completion of the group ring $\mathbb{Z}[K(Z)]$. (If $b^+(Z) \geq 1$ then $\Psi_{Z, s, \eta}$ lies in $\mathbb{Z}[[K(Z)]]$.) Indeed, $K(Z, \eta)$ is precisely the perturbed Floer homology of $T^3$ in the appropriate coefficient system. Note that $K(Z, \eta)$ can be identified with a multivariable Laurent series ring, which is polynomial in variables that pair trivially with $\eta$ (and some variables may have finite order, if there is torsion in the cokernel of $H^1(Z) \to H^1(\partial Z)$).

If $X = Z_1 \cup Z_2$ is obtained by gluing two 4–manifolds $Z_1$ and $Z_2$ with boundary $T^3$, and $\eta \in H^2(X; \mathbb{R})$ restricts nontrivially to the splitting 3–torus, then the pairing appearing in (4) is naturally identified with a multiplication map

$$K(Z_1, \eta) \otimes K(Z_2, \eta) \xrightarrow{\sim} M_{X,T^3,\eta} \subset \mathbb{Z}[[H^2(X; \mathbb{Z})]]$$

induced by the maps $j^*_1: H^2(Z_1, \partial Z_1) \to H^2(X)$ Poincaré dual to the inclusion homomorphisms. Thus Theorem 1.6 gives:

**Corollary 1.7** Let $X = Z_1 \cup_{\partial} Z_2$ be a 4–manifold obtained as the union of two manifolds $Z_1$ and $Z_2$ whose boundary is diffeomorphic to the 3–torus $T^3$, $\eta \in H^2(X; \mathbb{R})$ a class restricting nontrivially to $T^3$, and $s$ a spin$^c$ structure on $X$. Then

$$\Phi_{X,T^3,s,\eta} = j^*_1(\Psi_{Z_1,\eta,s}) j^*_2(\Psi_{Z_2,\eta,s})$$

In particular if $b^+(X) \geq 2$ then

$$\sum_{k \in \delta H^1(T^3)} \Phi_{X,s+k} e^k = j^*_1(\Psi_{Z_1,\eta,s}) j^*_2(\Psi_{Z_2,\eta,s})$$

up to sign and translation by an element of $\delta H^1(T^3)$, where $\delta: H^1(T^3) \to H^2(X)$ is the Mayer–Vietoris coboundary.

We deduce the fiber sum formulae in Theorem 1.1 and Theorem 1.4 from the following somewhat more general results, which apply in particular to the situation in which $M_1$, $M_2$, and/or $X$ have $b^+ = 1$. In each case, the perturbed invariants $\Phi_{M_i, \Sigma \times S^1}$ take values in $M_{M_i, \Sigma \times S^1, \eta}$, which is isomorphic to the ring $\mathcal{L}(t)$ of Laurent series in the variable $t$ corresponding to the Poincaré dual of the surface $\Sigma$. Each of the following is obtained by an application of (3), combined with knowledge of the relative invariants.
of manifolds of the form $\Sigma \times D^2$. In particular, Theorem 1.8 follows quickly from the fact that up to multiplication by $\pm t^n$,

$$
\Psi_{T^2 \times D^2, \eta, s} = \frac{1}{t - 1}
$$

where $s$ is the spin$^c$ structure with trivial first Chern class and $\eta \in H^2(T^2 \times D^2; \mathbb{R})$ has $\int_{T^2} \eta > 0$ (Proposition 10.3). Note that this implies that the complement $Z$ of a torus of square 0 in a closed 4–manifold $M$ has relative invariant satisfying

$$
\rho(\Psi_{Z, \eta, s}) = (t - 1) \Phi_{M, T^3, \eta, s},
$$

where $\eta$ is a class as above. To understand the homomorphism $\rho: \mathcal{K}(Z, \eta) \to \mathcal{L}(t)$, recall that $\mathcal{K}(Z, \eta)$ can be identified with a Laurent series ring in variables generating $K(Z) \cong H^1(\partial Z)/H^1(Z)$. Since $\eta$ is defined on $M$ (in particular $\eta$ extends from $\partial Z = T^3$ to $T^2 \times D^2$), its restriction to $T^3$ is a multiple of the Poincaré dual of the meridian circle $pt \times D^2$. Thus we can choose generators for $K(Z)$ in such a way that $\eta \cup t$ is nonzero, while $\eta$ pairs trivially with the other generators. Then there is a well-defined homomorphism $\rho: \mathcal{K}(Z, \eta) \to \mathcal{L}(t)$ that corresponds to setting the variables other than $t$ equal to 1 (for more detail on homomorphisms between Novikov rings see Section 8.1; this particular case is considered in Section 10, specifically Equation (32)).

**Theorem 1.8** Let $X = M_1 \#_{T_1} M_2$ be the fiber sum of two 4–manifolds $M_1, M_2$ along tori $T_1, T_2$ of square 0. Assume that there exist classes $\eta_i \in H^2(M_i; \mathbb{R})$, $i = 1, 2$, such that the restrictions of $\eta_i$ to $T_i \times S^1 \subset M_i$ correspond under the gluing diffeomorphism $f: T_1 \times S^1 \to T_2 \times S^1$, and assume that $\int_{T_i} \eta_i > 0$. Let $\eta \in H^2(X; \mathbb{R})$ be a class whose restrictions to $Z_i = M_i \setminus (T_i \times D^2)$ agree with those of $\eta_i$, and choose spin$^c$ structures $s_i \in \text{Spin}^c(M_i)$, $s \in \text{Spin}^c(X)$ whose restrictions correspond similarly. Then for any $\alpha \in \mathbb{A}(X)$, the image of $\alpha_1 \otimes \alpha_2$ under the map $\mathbb{A}(Z_1) \otimes \mathbb{A}(Z_2) \to \mathbb{A}(X)$, we have

$$
\rho(\Phi_{X, T \times S^1, \eta, s}(\alpha)) = (t^{1/2} - t^{-1/2})^2 \Phi_{M_1, T_1 \times S^1, \eta_1, s_1}(\alpha_1) \cdot \Phi_{M_2, T_2 \times S^1, \eta_2, s_2}(\alpha_2)
$$

up to multiplication by $\pm t^n$.

In the higher-genus case we have the following.

**Theorem 1.9** Let $X = M_1 \#_{\Sigma_1} M_2$ be the fiber sum of two 4–manifolds $M_1, M_2$ along surfaces $\Sigma_1, \Sigma_2$ of genus $g > 1$ and square 0. Let $\eta_1, \eta_2, \eta$ be 2–dimensional cohomology classes satisfying conditions analogous to those in the previous theorem, and choose spin$^c$ structures $s_1, s_2$, and $s$ restricting compatibly as before. If the
Chern classes of each spin$^c$ structure restrict to $\Sigma \times S^1$ as a class other than $2k \text{PD}[S^1]$ with $|k| \leq g - 1$ then the Ozsváth–Szabó invariants of all manifolds involved vanish. Otherwise, writing $f$ for the gluing map $\Sigma_1 \times S^1 \to \Sigma_2 \times S^1$, we have

$$\rho(\Phi_{Y, \Sigma \times S^1, \eta, \nu}(\alpha)) = \sum_{\beta} \Phi_{M_1, \Sigma_1 \times S^1, \eta_1, \nu_1}(\alpha_1 \otimes \beta) \cdot \Phi_{M_2, \Sigma_2 \times S^1, \eta_2, \nu_2}(\alpha_2 \otimes f_*(\beta^2)) \cdot u_{\beta, k}$$

up to multiplication by $\pm t^n$.

In this theorem, $\{\beta\}$ is a basis for $H_*(\text{Sym}^d \Sigma)$, $d = g - 1 - |k|$, as before, and $u_{\beta, k}$ is a polynomial in $t$ with constant coefficient 1, which is equal to 1 except possibly if $k = 0$.

The maps $\rho: M_{X, \Sigma \times S^1, \eta} \to L(t)$ appearing in Theorem 1.8 and Theorem 1.9 are “change of coefficient” homomorphisms as before, defined in (32) below.

### 1.4 Examples

#### 1.4.1 Elliptic surfaces

For $n \geq 1$, let $E(n)$ denote the smooth 4–manifold underlying a simply connected minimal elliptic surface with no multiple fibers and holomorphic Euler characteristic $n$. In [13], Ozsváth and Szabó calculated that $\text{OS}_{E(2)} = 1$, meaning that $\Phi_{E(2), s}$ is trivial on all spin$^c$ structures $s$ with $c_1(s) \neq 0$, while if $c_1(s) = 0$ then $\Phi_{E(2), s} = 1$. We infer a posteriori that $E(2)$ has simple type.

In general, we have that $E(n)$ is diffeomorphic to the fiber sum of $n$ copies of the rational elliptic surface $E(1) = \mathbb{C}P^2 \# 9\overline{\mathbb{C}P}^2$, summed along copies of the torus fiber $F$ of the elliptic fibration, using the fibration structure to identify neighborhoods of the fibers. From Theorem 1.8 we infer that the perturbed Ozsváth–Szabó invariant of $E(1)$, calculated with respect to the splitting along the boundary of a neighborhood of $F$ and using a spin$^c$ structure whose Chern class restricts trivially to the complement of $F$, is given by the Laurent series $(t - 1)^{-1}$, up to multiplication by $\pm t^n$. For other spin$^c$ structures the perturbed invariant vanishes.

It is straightforward to deduce from this and Theorem 1.4 that for $n \geq 2$,

$$\text{OS}_{E(n)} = (T - T^{-1})^{n-2},$$

where $T$ is the class Poincaré dual to a regular fiber. In fact, Theorem 1.4 gives this after summing over rim tori using the homomorphism $\rho$ on the left hand side. Arguments based on the adjunction inequality [15, Theorem 1.5], familiar from Seiberg–Witten theory [2], show that only multiples of $T$ can contribute to $\text{OS}_{E(n)}$ and therefore
application of $\rho$ is unnecessary. Likewise, the only ambiguity remaining in the formula above is an overall sign; the conjugation-invariance of $\Phi_{X,s}$ when $b^+(X) \geq 2$ due to Ozsváth and Szabó [15, Theorem 3.6] shows that $\text{OS}_{E(n)}$ must be a symmetric polynomial.

**1.4.2 Higher-genus sums** The elliptic surface $E(n)$ can be realized as the double branched cover of $S^2 \times S^2$, branched along a surface obtained by smoothing the union of 4 parallel copies of $S^2 \times \{pt\}$ and $2n$ copies of $\{pt\} \times S^2$. The projection $\pi_1: S^2 \times S^2 \to S^2$ to the first factor lifts to an elliptic fibration on $E(n)$, while projection $\pi_2$ on the second factor realizes $E(n)$ as a fibration with typical fiber a surface $\Sigma$ of genus $n-1$, which can be perturbed to be a Lefschetz fibration if desired. Note that $\Sigma$ intersects the fiber $F$ of the elliptic fibration in two (positive) points. Let $X_n = E(n) \# \Sigma(n)$ denote the fiber sum of two copies of $E(n)$ along $\Sigma$, and suppose $n \geq 3$. We wish to use Theorem 1.1 to calculate the Ozsváth–Szabó invariants of $X_n$.

A useful observation is that $E(n)$ has simple type by the example above. Corollary 1.2 then shows that we can have a nontrivial contribution to $\rho(\text{OS}_{X_n})$ only when $|k| = g - 1$, i.e., from spin$^c$ structures $s$ with $|\langle c_1(s), [\Sigma] \rangle| = 2g - 2 = 2n - 4$. From the preceding example and the fact that $|\langle [\Sigma], [F] \rangle| = 2$, the right-hand side of (1) in the case $|k| = g - 1$ is equal to $\pm 1$, being the product of the invariants arising from $T^{\pm(n-2)}$. Since $T^{\pm(n-2)}$ is equal (up to sign) to the first Chern class $c_1(E(n))$, a convenient way to express these conclusions is that $\text{OS}_{X_n} = \pm K \pm K^{-1}$, where $K$ is the canonical class on $X_n$. This formula is true after summing over rim tori.

Note that $X_n$ is diffeomorphic to a minimal complex surface of general type, and therefore this calculation agrees with the corresponding one in Seiberg–Witten theory; see Witten [22].

**1.5 Organization**

The first goal of the paper is to set up enough machinery for the proof of Theorem 1.5. To this end, the next section recalls the definition of Heegaard Floer homology with twisted coefficients from [12] and the corresponding constructions associated to 4–dimensional cobordisms in [15]. Section 3 discusses a refinement of the relative grading on Heegaard Floer homology, available with twisted coefficients. Sections 4, 5 and 6 extend other algebraic features of Heegaard Floer homology to the twisted-coefficient setting, including the pairing mentioned in Theorem 1.5 and the action on Floer homology by $H_1(Y; \mathbb{Z})$/tors which is useful in later calculations. With this machinery in place, Section 7 proves Theorem 1.5. Section 8 defines perturbed Heegaard Floer theory, and deals with the extension of many of the results in preceding
sections to that case; in particular Theorem 1.6. After making the necessary Floer homology calculations in Section 9, Section 10 gives the proofs of Theorem 1.8 and Theorem 1.9, and thence Theorem 1.1 and Theorem 1.4. We conclude with some remarks on manifolds of simple type in Section 11.

2 Preliminaries on twisted coefficients

2.1 Definitions

We briefly recall the construction of the Heegaard Floer homology groups with “twisted” coefficients. For more details, the reader is referred to Ozsváth–Szabó [12; 11].

To a closed oriented 3–manifold $Y$ we can associate a pointed Heegaard diagram $(\Sigma, \alpha, \beta, z)$ where $\Sigma$ is a surface of genus $g \geq 1$ and $\alpha = \alpha_1, \ldots, \alpha_g$ and $\beta = \beta_1, \ldots, \beta_g$ are sets of attaching circles for the two handlebodies in the Heegaard decomposition. We consider intersection points between the $g$–dimensional tori $T_\alpha = \alpha_1 \times \cdots \times \alpha_g$ and $T_\beta = \beta_1 \times \cdots \times \beta_g$ in the symmetric power $\text{Sym}^g(\Sigma)$, which we assume intersect transversely. Recall that the basepoint $z$, chosen away from the $\alpha_i$ and $\beta_i$, gives rise to a map $s_z: T_\alpha \cap T_\beta \to \text{Spin}^c(Y)$. Given a spin$^c$ structure $s$ on $Y$, and under suitable admissibility hypotheses on the Heegaard diagram, the generators for the Heegaard Floer chain complex $CF^\infty(Y, s)$ are pairs $[x, i]$ where $i \in \mathbb{Z}$ and $x \in T_\alpha \cap T_\beta$ satisfies $s_z(x) = s$.

The differential in $CF^\infty$ counts certain maps $u: D^2 \to \text{Sym}^g(\Sigma)$ of the unit disk in $\mathbb{C}$ that connect pairs of intersection points $x$ and $y$. That is to say, we consider maps $u$ satisfying the boundary conditions:

\[
\begin{align*}
  u(e^{i\theta}) &\in T_\alpha \text{ for } \cos \theta \geq 0 & u(i) &= y \\
  u(e^{i\theta}) &\in T_\beta \text{ for } \cos \theta \leq 0 & u(-i) &= x.
\end{align*}
\]

For $g > 2$ we let $\pi_2(x, y)$ denote the set of homotopy classes of such maps; for $g = 2$ we let $\pi_2(x, y)$ be the quotient of the set of such homotopy classes by a further equivalence, the details of which need not concern us (see Ozsváth–Szabó [12]).

There is a topological obstruction to the existence of any such disk connecting $x$ and $y$, denoted $e(x, y) \in H_1(Y; \mathbb{Z})$. To any homotopy class $\phi \in \pi_2(x, y)$ we can associate the quantity $n_z(\phi)$, being the algebraic intersection number between $\phi$ and the subvariety $\{z\} \times \text{Sym}^{g-1}(\Sigma)$. The following is a basic fact in Heegaard Floer theory:
Proposition 2.1 [12, Proposition 2.15] Suppose $g > 1$ and let $x, y \in T_\alpha \cap T_\beta$. If $\epsilon(x, y) \neq 0$ then $\pi_2(x, y)$ is empty, while if $\epsilon(x, y) = 0$ then there is an affine isomorphism
\[
\pi_2(x, y) = \mathbb{Z} \oplus H^1(Y; \mathbb{Z}),
\]
such that the projection $\pi_2(x, y) \to \mathbb{Z}$ is given by the map $n_z$.

We remark that if $x = y$, then the isomorphism in the above proposition is natural (not merely affine).

There is a natural “splicing” of homotopy classes
\[
\pi_2(x, y) \times \pi_2(y, z) \to \pi_2(x, z),
\]
as well as an action
\[
\pi'_2(\text{Sym}^g(\Sigma_g)) \times \pi_2(x, y) \to \pi_2(x, y),
\]
where $\pi'_2$ denotes the second homotopy group divided by the action of the fundamental group. (For $g > 1$, $\pi'_2(\text{Sym}^g(\Sigma_g)) \cong \mathbb{Z}$, generated by a class $S$ with $n_z(S) = 1$. When $g > 2$, $\pi'_2(\text{Sym}^g(\Sigma_g)) = \pi_2(\text{Sym}^g(\Sigma_g))$. The isomorphism in the above proposition is affine in the sense that it respects the splicing action by $\pi_2(x, x)$, under the natural identification $\pi_2(x, x) = \mathbb{Z} \oplus H^1(Y)$.

The ordinary “untwisted” version of Heegaard Floer homology takes $CF^\infty$ to be generated (over $\mathbb{Z}$) by pairs $[x, i]$ as above, equipped with a boundary map such that the coefficient of $[y, j]$ in the boundary of $[x, i]$ is the number of pseudo-holomorphic maps in all homotopy classes $\phi \in \pi_2(x, y)$ having moduli spaces of formal dimension 1 and $n_z(\phi) = i - j$. The twisted version is similar, but where one keeps track of all possible homotopy data associated to $\phi$. In light of the above proposition, this means that we should form a chain complex freely generated by intersection points $x$ as a module over the group ring of $\mathbb{Z} \oplus H^1(Y)$, or equivalently by pairs $[x, i]$ over the group ring of $H^1(Y)$. Following [11, Section 8.1], we define:

Definition 2.2 An additive assignment for the diagram $(\Sigma, \alpha, \beta, z)$ is a collection of functions
\[
A_{x,y} : \pi_2(x, y) \to H^1(Y; \mathbb{Z})
\]
that satisfies the following:

1. $A_{x,z}(\phi * \psi) = A_{x,y}(\phi) + A_{y,z}(\psi)$ whenever $\phi \in \pi_2(x, y)$ and $\psi \in \pi_2(y, z)$.
2. $A_{x,y}(S * \phi) = A_{x,y}(\phi)$ for $S \in \pi'_2(\text{Sym}^g(\Sigma_g))$. 

*Geometry & Topology, Volume 12 (2008)*
We will drop the subscripts from $A_{x,y}$ whenever possible. It is shown in [11] how a certain finite set of choices (a “complete set of paths”) gives rise to an additive assignment in the above sense. We can also assume that $A_{x,y}: \pi_2(x,y) \cong \mathbb{Z} \oplus H^1(Y) \to H^1(Y)$ is the natural projection on the second factor.

**Definition 2.3** Let $(\Sigma, \alpha, \beta, z)$ be a pointed Heegaard diagram for $Y$ and $s \in \text{Spin}^c(Y)$. Fix an additive assignment $A$ for the diagram. The twisted Heegaard Floer chain complex $CF^\infty(Y, s; \mathbb{Z}[H^1(Y)])$ is the module freely generated over $\mathbb{Z}[H^1(Y)]$ by pairs $[x,i]$, with differential $\partial^\infty$ given by

$$\partial^\infty[x,i] = \sum_{y \in T_\alpha \cap T_\beta} \sum_{\phi \in \pi_2(x,y)} \# \mathcal{M}(\phi) \cdot e^A(\phi)[y,i - n_z(\phi)],$$

where the symbol $e^A(\phi)$ indicates the variable in $\mathbb{Z}[H^1(Y)]$ corresponding to $A(\phi)$.

Here $\mathcal{M}(\phi)$ denotes the space of holomorphic disks in the homotopy class $\phi$, where “holomorphic” is defined relative to an appropriately generic path of almost-complex structure on $\text{Sym}^g(\Sigma)$. For such a path, $\mathcal{M}(\phi)$ is a smooth manifold of dimension given by a Maslov index $\mu(\phi)$. There is an action of $\mathbb{R}$ on $\mathcal{M}(\phi)$ by reparametrization of the disk, and $\tilde{\mathcal{M}}(\phi)$ denotes the quotient of $\mathcal{M}(\phi)$ by this action. When $\mu(\phi) = 1$, $\tilde{\mathcal{M}}(\phi)$ is a compact, zero-dimensional manifold. An appropriate choice of “coherent orientation system” serves to orient the points of $\tilde{\mathcal{M}}(\phi)$ in this case, and $\# \tilde{\mathcal{M}}(\phi)$ denotes the signed count of these points. It is shown in [12; 11] that under appropriate admissibility hypotheses on the diagram $(\Sigma, \alpha, \beta, z)$ the chain homotopy type of $CF^\infty(Y, s; \mathbb{Z}[H^1(Y)])$ is an invariant of $(Y, s)$.

As in the introduction, in much of what follows we will write $R_Y$ for the ring $\mathbb{Z}[H^1(Y)]$, or simply $R$ when the underlying 3–manifold is apparent from context. Note that by choosing a basis for $H^1(Y)$ we can identify $R$ with the ring of Laurent polynomials in $b_1(Y)$ variables.

By following the usual constructions of Heegaard Floer homology, we obtain other variants of the above with coefficients in $R_Y$: namely by considering only generators $[x,i]$ with $i < 0$ we obtain a subcomplex $CF^-(Y, s; R)$ whose quotient complex is $CF^+(Y, s; R)$, with associated homology groups $HF^-$ and $HF^+$ respectively. There is an action $U: [x,i] \mapsto [x,i - 1]$ on $CF^\infty$ as usual; the kernel of the induced action on $CF^+$ is written $\widehat{CF}$ with homology $\widehat{HF}(Y, s; R)$. There is a relative grading on the Floer complex with respect to which $U$ decreases degree by 2; we will discuss gradings further in Section 3.
Given any module $M$ for $R_Y$ we can form Heegaard Floer homology with coefficients in $M$ by taking the homology of the complex $\text{CF}_{\mathcal{R}} M$. In particular if $M = \mathbb{Z}$, equipped with the action of $R_Y$ by which every element of $H^1(Y)$ acts as the identity, we recover the ordinary untwisted theory.

For use in later sections, we introduce the following notion of conjugation of $R_Y$–modules. First, observe that the automorphism $x \mapsto -x$ of $H^1(Y)$ induces an automorphism $R_Y \to R_Y$ that we refer to as conjugation, and write as $r \mapsto \bar{r}$ for $r \in R_Y$. Now if $M$ is a module for $R_Y$, we let $\tilde{M}$ denote the additive group $M$ equipped with the “conjugate” module structure in which module multiplication is given by

$$r \otimes m \mapsto \bar{r} \cdot m$$

for $r \in R_Y$ and $m \in \tilde{M}$.

### 2.2 Twisted cobordism invariants

We now sketch the construction and main properties of twisted-coefficient Heegaard Floer invariants associated to cobordisms, which can be found in greater detail in [15].

Recall that if $W: Y_1 \to Y_2$ is an oriented 4–dimensional cobordism and $M$ is a module for $R_1 := R_{Y_1} = \mathbb{Z}[H^1(Y_1)]$, then there is an induced module $M(W)$ for $R_2 = R_{Y_2}$ defined as follows. Let

$$K(W) = \ker(H^2(W, \partial W) \to H^2(W))$$

be the kernel of the map in the long exact sequence for the pair $(W, \partial W)$: then $\mathbb{Z}[K(W)]$ is a module for $R_1$ and $R_2$ via the coboundary maps $H^1(Y_i) \to K(W) \subset H^2(W, \partial W)$. Define

$$M(W) = \tilde{M} \otimes_{R_1} \mathbb{Z}[K(W)].$$

Then $M(W)$ is a module for $R_2$ in the obvious way. The reason for the appearance of the conjugate module $\tilde{M}$ above has to do with the fact that the orientation of $W$ induces the opposite orientation on $Y_1$ from the given one, and will be explained more fully in the next section.

Ozsváth and Szabó show in [15] how to associate to a cobordism $W$ as above with spin$^c$ structure $s$ a homomorphism

$$F_{W,s}^\circ: HF^\circ(Y_1, s_1; M) \to HF^\circ(Y_2, s_2; M(W))$$

(where $s_i$ denotes the restriction of $s$ to $Y_i$, and $\circ$ indicates a map between each of the varieties of Heegaard Floer homology, respecting the long exact sequences relating
them). This is defined as a composition

$$F_W^* = E^* \circ H^* \circ G^*,$$

where $G^*$ is associated to the 1–handles in $W$, $H^*$ to the 2–handles, and $E^*$ to the 3–handles. Note that the coefficient module remains unchanged by cobordisms consisting of 1– or 3–handle additions. Indeed, such cobordisms induce homomorphisms in an essentially formal way, so we simply refer the reader to [15, Section 4.3] for the definition of $E^*$ and $G^*$.

Suppose that $W$ is a cobordism consisting of 2–handle additions, so that we can think of $W$ as associated to surgery on a framed link $L \subset Y_1$. In this situation, Ozsváth and Szabó construct a “Heegaard triple” $(\Sigma, \alpha, \beta, \gamma, z)$ associated to $W$. This diagram describes three 3–manifolds $Y_{\alpha\beta}$, $Y_{\beta\gamma}$ and $Y_{\alpha\gamma}$ obtained by using the indicated circles on $\Sigma$ as attaching circles, such that

$$Y_{\alpha\beta} = Y_1, \quad Y_{\beta\gamma} = \#^k S^1 \times S^2, \quad Y_{\alpha\gamma} = Y_2,$$

where $k$ is the genus of $\Sigma$ minus the number of components of $L$. In fact the diagram $(\Sigma, \alpha, \beta, \gamma, z)$ describes a 4–manifold $X_{\alpha\beta\gamma}$ in a natural way, whose boundaries are the three manifolds above. Furthermore, in the current situation, $X_{\alpha\beta\gamma}$ is obtained from $W$ by removing the regular neighborhood of a 1–complex (see [15, Proposition 4.3]).

We can arrange that the top-dimensional generator of

$$HF^{\leq 0}(Y_{\beta\gamma}, s_0; \mathbb{Z}) \cong \Lambda^* H^1(Y_{\beta\gamma}; \mathbb{Z}) \otimes \mathbb{Z}[U]$$

is represented by an intersection point $\Theta \in T_{\beta} \cap T_{\gamma}$ (here $s_0$ denotes the spin$^c$ structure on $\#^k S^1 \times S^2$ having $c_1(s_0) = 0$). The map $F^*$ is defined by counting holomorphic triangles, with the aid of another additive assignment. To describe this, suppose $x \in T_{\alpha} \cap T_{\beta}$, $y \in T_{\beta} \cap T_{\gamma}$, and $w \in T_{\alpha} \cap T_{\gamma}$ are intersection points arising from a Heegaard triple $(\Sigma, \alpha, \beta, \gamma, z)$. Let $\Delta$ denote a standard 2–simplex, and write $\pi_2(x, y, w)$ for the set of homotopy classes of maps $u: \Delta \to \text{Sym}^g(\Sigma)$ that send the boundary arcs of $\Delta$ into $T_{\alpha}$, $T_{\beta}$, and $T_{\gamma}$ respectively, under a clockwise ordering of the boundary arcs $e_\alpha$, $e_\beta$, and $e_\gamma$ of $\Delta$, and such that

$$u(e_\alpha \cap e_\beta) = x, \quad u(e_\beta \cap e_\gamma) = y, \quad u(e_\alpha \cap e_\gamma) = w.$$ 

Again there is a topological obstruction $\epsilon(x, y, w) \in H_1(X_{\alpha\beta\gamma}; \mathbb{Z})$ that vanishes if and only if $\pi_2(x, y, w)$ is nonempty. The analogue of Proposition 2.1 in this context is the following.
Proposition 2.4 [12, Proposition 8.3] Let \((\Sigma, \alpha, \beta, \gamma, z)\) be a pointed Heegaard triple as above, and \(X_{\alpha\beta\gamma}\) the associated 4–manifold. Then whenever \(\epsilon(x, y, w) = 0\) we have an (affine) isomorphism
\[
\pi_2(x, y, w) \cong \mathbb{Z} \oplus H_2(X_{\alpha\beta\gamma}; \mathbb{Z})
\]
where the projection to \(\mathbb{Z}\) is given by \(\psi \mapsto n_z(\psi)\).

There is an obvious “splicing” action on homotopy classes of triangles by disks on each corner; the above identification respects this action.

Recall from [12, Section 8.1] that the basepoint \(z\) gives rise to a map
\[
s_z : \bigcup_{x,y,w} \pi_2(x, y, w) \to \text{Spin}^c(X_{\alpha\beta\gamma}),
\]
such that triangles \(\psi \in \pi_2(x, y, w)\) and \(\psi' \in \pi_2(x', y', w')\) have \(s_z(\psi) = s_z(\psi')\) if and only if there exist disks \(\phi_x \in \pi_2(x, x')\), \(\phi_y \in \pi_2(y, y')\) and \(\phi_w \in \pi_2(w, w')\) with \(\psi' = \psi + \phi_x + \phi_y + \phi_w\). In this case \(\psi\) and \(\psi'\) are said to be spin\(^c\) equivalent. Note that in case \((\Sigma, \alpha, \beta, \gamma, z)\) describes a 2–handle cobordism \(W\) as previously, we can think of \(s_z\) as a function
\[
s_z : \bigcup_{x,w} \pi_2(x, \Theta, w) \to \text{Spin}^c(W).
\]

Definition 2.5 An additive assignment for a Heegaard triple \((\Sigma, \alpha, \beta, \gamma, z)\) describing a 2–handle cobordism \(W : Y_1 \to Y_2\) as above is a function
\[
A_W : \bigcup_{s \in \text{Spin}^c(W)} s_z^{-1}(s) \to K(W)
\]
obtained in the following manner. For a fixed \(\psi_0 \in s_z^{-1}(s)\), let \(\psi = \psi_0 + \phi_{\alpha\beta} + \phi_{\beta\gamma} + \phi_{\alpha\gamma}\) be an arbitrary element of \(s_z^{-1}(s)\). Then set
\[
A_W(\psi) = \delta(-A_1(\phi_{\alpha\beta}) + A_2(\phi_{\alpha\gamma}))
\]
where \(A_i\) are additive assignments for \(Y_i\) and \(\delta : H^1(\partial W) \to H^2(W, \partial W)\) is the coboundary from the long exact sequence of \((W, \partial W)\).

We are now in a position to define the map on Floer homology induced by \(W\) (given additive assignments on \(Y_1, Y_2,\) and \(W\)). We again refer to [15, Section 4] for the details required to make full sense of the following.
Definition 2.6 For a triple \((\Sigma, \alpha, \beta, \gamma, z)\) describing a 2–handle cobordism \(W\) with spin\(^c\) structure \(s\), we define
\[
F_{W,s}^*: HF^0(Y_1, s_1; M) \to HF^0(Y_2, s_2; M(W)),
\]
where \(s_i = s|_{Y_i}\), to be the map induced on homology by the chain map
\[
[x, i] \mapsto \sum_{w \in T_0 \cap T_\gamma} \sum_{\psi \in \pi_2(x, \Theta, w)} \# \mathcal{M}(\psi) \cdot [w, i - n_z(\psi)] \otimes e^{A_W(\psi)}.
\]
Here \(\mu(\psi)\) denotes the expected dimension of the moduli space \(\mathcal{M}(\psi)\) of pseudo-holomorphic triangles in the homotopy class \(\psi\), and \(\# \mathcal{M}(\psi)\) indicates the signed count of points in a compact oriented 0–dimensional manifold.

We should note that while the Floer homology \(HF^0(Y, s; M)\) does not depend on the additive assignment \(A_Y\), the map \(F_{W,s}\) does depend on the choice of \(A_W\) as in Definition 2.5 through the reference triangle \(\psi_0\). Changing this choice has the effect of precomposing (postcomposing) \(F_W\) with the action of an element of \(H^1(Y_1)\) (resp \(H^1(Y_2)\)), which in turn act in \(M(W)\) via the coboundary. Likewise the generator \(\Theta\) is determined only up to sign, so that \(F_W\) has a sign indeterminacy as well. Following [15], we let \([F_{W,s}]\) denote the orbit of \(F_{W,s}^*\) under the action of \(H^1(Y_1) \oplus H^1(Y_2)\).

With the conventions employed here \(F_{W,s}^*\) is “antilinear” with respect to the action of \(R_{Y_1}\), meaning that \(F_{W,s}^*(r \xi) = \overline{r} F_{W,s}^*(\xi)\) for \(r \in R_{Y_1}\).

2.3 Composition law

An advantage to using twisted coefficient modules for Heegaard Floer homology is the availability of a refined composition law in this situation. To describe this, we must first understand the behavior of the coefficient modules themselves under composition of cobordisms. The following lemma will be useful in formulating results to come; as usual, ordinary (co)homology is taken with integer coefficients.

Lemma 2.7 Let \(W = W_1 \cup_{Y_1} W_2\) be the composition of two cobordisms \(W_1: Y_0 \to Y_1\) and \(W_2: Y_1 \to Y_2\). Define
\[
K(W, Y_1) = \ker[\rho_1 \oplus \rho_2: H^2(W, \partial W) \to H^2(W_1) \oplus H^2(W_2)],
\]
where \(\rho_i\) denotes the restriction map \(H^2(W, \partial W) \to H^2(W_i)\). Then
\[
\mathbb{Z}[K(W_1)] \otimes \mathbb{Z}[H^1(Y_1)] \cong \mathbb{Z}[K(W, Y_1)]
\]
as modules over \(\mathbb{Z}[H^1(Y_0)]\) and \(\mathbb{Z}[H^1(Y_2)]\).
Proof We have

\[ 
\mathbb{Z}[K(W_1)] \otimes_{\mathbb{Z}[H^1(Y_1)]} \mathbb{Z}[K(W_2)] \cong \mathbb{Z}
\left[ \frac{K(W_1) \oplus K(W_2)}{H^1(Y_1)} \right],
\]

so the claim amounts to exhibiting an isomorphism

\[ 
\frac{K(W_1) \oplus K(W_2)}{H^1(Y_1)} \cong K(W, Y_1).
\]

To see this, consider the diagram

\[ 
\begin{array}{ccc}
H^1(Y_1) & \longrightarrow & H^2(W_1, \partial W_1) \oplus H^2(W_2, \partial W_2) \\
& & \downarrow f \\
H^2(W_1) \oplus H^2(W_2),
\end{array}
\]

where the horizontal row is (the Poincaré dual of) the Mayer–Vietoris sequence. Write

\[ 
i_*: H^2(W_1, \partial W_1) \rightarrow H^2(W, \partial W) \quad \text{and} \quad j_*: H^2(W_2, \partial W_2) \rightarrow H^2(W, \partial W)
\]

for the components of \( f \); then it is not hard to see that

\[ 
\rho_1 \circ i_*: H^2(W_1, \partial W_1) \rightarrow H^2(W_1) \quad \text{and} \quad \rho_2 \circ j_*: H^2(W_2, \partial W_2) \rightarrow H^2(W_2)
\]

agree with the maps induced by inclusion, while

\[ 
\rho_2 \circ i_* = 0 \quad \text{and} \quad \rho_1 \circ j_* = 0.
\]

From this it is easy to deduce that \( f^{-1}(K(W, Y_1)) = K(W_1) \oplus K(W_2) \), from which the lemma follows.

Remark 2.8 If \( W \) is a cobordism between homology spheres, or more generally if \( H^2(W, \partial W) \rightarrow H^2(W) \) is an isomorphism, then there is an identification

\[ 
K(W, Y_1) = \ker[H^2(W) \rightarrow H^2(W_1) \oplus H^2(W_2)],
\]

the kernel of the restriction map in the ordinary Mayer–Vietoris sequence in cohomology. In this case if \( s_1 \) and \( s_2 \) are spin\(^c\) structures on \( W_1 \) and \( W_2 \), then \( K(W, Y_1) \) parametrizes spin\(^c\) structures \( s \) on \( W \) such that \( s|_{W_i} = s_i \) (when that set is nonempty). In the case of a closed 4–manifold \( X \), the module \( M_{X,Y} \) of the introduction is simply \( \mathbb{Z}[K(W, Y)] \) where \( W \) is obtained from \( X \) by removing a 4–ball on each side of \( Y \).

When regarding \( W \) as a single cobordism the group relevant to twisted coefficient modules is \( K(W) \), while if \( W = W_1 \cup W_2 \) is viewed as a composite the coefficient
modules change by tensor product with the group ring of \( K(W, Y_1) \) (in light of the lemma above). By commutativity of the diagram

\[
\begin{array}{ccc}
H^2(W, \partial W) & \rightarrow & H^2(W) \\
\downarrow \phi_1 \oplus \phi_2 & & \downarrow \\
H^2(W_1) \oplus H^2(W_2).
\end{array}
\]

there is a natural inclusion \( \iota: K(W) \rightarrow K(W, Y_1) \). This gives rise to a projection map

\[
\Pi: \mathbb{Z}[K(W, Y_1)] \rightarrow \mathbb{Z}[K(W)].
\]

namely (cf [15, Section 3.1])

\[
\Pi(e^w) = \begin{cases} 
  e^w & \text{if } w = \iota(v) \text{ for some } v \\
  0 & \text{otherwise.}
\end{cases}
\]

Equivalently, if we think of a group ring \( \mathbb{Z}[G] \) as a set of functions \( G \rightarrow \mathbb{Z} \), then \( \Pi \) corresponds to the restriction of functions on \( K(W, Y_1) \) to \( K(W) \).

Thus, if \( M \) is a module for \( \mathbb{Z}[H^1(Y_0)] \) we obtain a map

\[
\Pi_M: M(W_1)(W_2) \rightarrow M(W)
\]

by tensor product of the identity with \( \Pi \) under the identifications

\[
M(W_1)(W_2) = \overline{M} \otimes_{\mathbb{Z}[H^1(Y_0)]} \mathbb{Z}[K(W, Y_1)]
\]

and

\[
M(W) = \overline{M} \otimes_{\mathbb{Z}[H^1(Y_0)]} \mathbb{Z}[K(W)].
\]

The refined composition law for twisted coefficients can be stated as follows.

**Theorem 2.9** [15, Theorem 3.9] *Let* \( W = W_1 \cup_{Y_1} W_2 \) *be a composite cobordism as above with spin\(^c\) structure* \( s \). *Write* \( s_i = s|_{W_i} \). *Then there are choices of representatives for the various maps involved such that*

\[
[F_{W, s}^\circ] = [\Pi_M \circ F_{W_2, s_2}^\circ \circ F_{W_1, s_1}^\circ].
\]

*More generally, if* \( h \in H^1(Y_1) \) *then for these choices we have*

\[
[F_{W, s-\delta h}^\circ] = [\Pi_M \circ F_{W_2, s_2}^\circ \circ e^h \cdot F_{W_1, s_1}^\circ],
\]

*where* \( \delta h \) *is the image of* \( h \) *under the Mayer–Vietoris coboundary* \( H^1(Y_1) \rightarrow H^2(W) \).*

*Geometry & Topology, Volume 12 (2008)*
We should also remark that for a cobordism $W: Y_1 \to Y_2$ with spin$^c$ structure $s$ the map
\[ F_{W,s} : HF^\otimes(Y_1,s_1;Z) \to HF^\otimes(Y_2,s_2;Z) \]
in untwisted Floer homology can be obtained from the twisted-coefficient map
\[ HF^\otimes(Y_1,s_1;\mathbb{Z}) \to HF^\otimes(Y_2,s_2;\mathbb{Z}(W)) \]
(here $\mathbb{Z}(W)$ is the module $M(W)$ with $M = \mathbb{Z}$, namely $\mathbb{Z}(W) = \mathbb{Z} \otimes \mathbb{Z}[H_1(Y)]$ $\mathbb{Z}[K(W)] = \mathbb{Z}[^{\ker(H^2(W,Y_2) \to H^2(W))}]$) by composition with the map $\epsilon_s$ induced in homology by the homomorphism
\[ \epsilon : \mathbb{Z}(W) \to \mathbb{Z} \]
of coefficient modules that sends each element of $\ker(H^2(W,Y_2) \to H^2(W))$ to 1.

3 Refined relative gradings

The $\mathbb{Z}$–coefficient version of Heegaard Floer homology is naturally a relatively cyclically graded theory, in general. This means that if $S = \{ [x,i] \mid s_2(x) = s \}$ denotes the natural generating set for $CF^\infty(Y,s;\mathbb{Z})$ then there is a map
\[ \text{gr} : S \times S \to \mathbb{Z}/\partial(s)\mathbb{Z}, \]
where
\[ \partial(s) = \gcd\{c_1(s),h) \mid h \in H_2(Y;\mathbb{Z})\} \]
is the divisibility of $c_1(s)$ (or by abuse of language, of $s$ itself). The differential in $CF^\infty$ has degree $-1$ with respect to this grading, while the endomorphism $U$ has degree $-2$.

In the case of fully twisted coefficients (coefficients in $\mathbb{Z}[H^1(Y)]$), Ozsváth and Szabó [11, Section 8] observe that there is a lift of this cyclic grading to a relative $\mathbb{Z}$–grading. Here we provide an extension of this construction to Floer homology with coefficients in an arbitrary (graded) module $M$, in which elements of $H^1(Y) \subset R_Y$ are explicitly assigned nontrivial degrees depending on their Chern numbers. That the action of such elements on fully-twisted Floer homology shifts degree by their Chern numbers is implicit in the definition given in [11].

**Definition 3.1** Fix a closed, oriented, spin$^c$ 3–manifold $(Y,s)$. Define the $s$–grading of $\mathbb{Z}[H^1(Y)]$ by
\[ \langle x \rangle = -(c_1(s) \cup x, [Y]) \quad \text{for } x \in H^1(Y). \]
The $s$–grading makes $\mathbb{Z}[H^1(Y)]$ into a graded ring, isomorphic to a multivariable Laurent polynomial ring in which the variables have degrees determined by their negative Chern numbers (5). When thinking of $\mathbb{Z}[H^1(Y)]$ as a graded ring, we write it as $R_{Y,s}$ or just $R_Y$. It is important to recognize that this grading depends on both the spin$^c$ structure $s$ and the orientation of $Y$, though we usually do not include $s$ in the notation. In particular, if $-Y$ denotes the 3–manifold $Y$ with its orientation reversed, then although $R_{Y,s} = R_{-Y,s}$ as sets, the gradings have opposite sign. On the other hand, the conjugation homomorphism $c: r \mapsto \overline{r}$ induces an isomorphism of graded rings $c: R_{Y,s} \to R_{-Y,s}$.

**Definition 3.2** Let $(\Sigma, \alpha, \beta, z)$ be a marked Heegaard triple describing the 3–manifold $Y$. Fix a spin$^c$ structure $s$ for $Y$ and an additive assignment $\{A_{x,y}\}$ for the diagram. The relative $\mathbb{Z}$ grading between generators $[x, i]$ and $[y, j]$ for $CF^\infty(Y, s; R_Y)$ is defined by

\begin{equation}
\text{gr}([x, i], [y, j]) = \mu(\phi) + 2(i - j) - 2n_z(\phi) - \langle c_1(s) \cup A_{x,y}(\phi), [Y] \rangle,
\end{equation}

where $\phi$ is any element of $\pi_2(x, y)$. More generally, if $r_1, r_2 \in R_Y$ are homogeneous elements, then we set

\[\text{gr}(r_1 \cdot [x, i], r_2 \cdot [y, j]) = \text{gr}([x, i], [y, j]) + \text{gr}_s(r_1) - \text{gr}_s(r_2).\]

It is not hard to check that the expression (6) is independent of the choice of $\phi \in \pi_2(x, y)$, and that the differential in $CF^\infty(Y, s; R_Y)$ has relative degree $-1$ with respect to the above grading.

Now suppose $M$ is a module for $R_Y$, which is equipped with a grading $\text{gr}_M$ satisfying

\begin{equation}
\text{gr}_M(r \cdot m) = \text{gr}_s(r) + \text{gr}_M(m).
\end{equation}

(Here we suppose $R_Y$ is equipped with the $s$–grading induced by some $s \in \text{Spin}^c(Y)$.)

Then the twisted Floer complex $CF(Y, s; M) = CF(Y, s; R_Y) \otimes_{R_Y} M$ naturally carries a relative $\mathbb{Z}$ grading given by

\[\text{gr}(m_1 [x, i], m_2 [y, j]) = \text{gr}([x, i], [y, j]) + \text{gr}_M(m_1) - \text{gr}_M(m_2),\]

inducing a relative $\mathbb{Z}$ grading on the Floer homology with coefficients in $M$.

More generally, if (7) holds modulo some integer $d \in \mathbb{Z}$, we obtain a relative $\mathbb{Z}/d\mathbb{Z}$ grading on $CF(Y, s; M)$. For example, taking $M = \mathbb{Z}$ to be the trivial $R_Y$–module supported in grading 0, we have for $n \in \mathbb{Z}$ and $r \in H^1(Y)$,

\[\text{gr}_M(r \cdot n) = \text{gr}_M(n) = 0 \quad \text{while} \quad \text{gr}_s(r) + \text{gr}_M(n) = -\langle c_1(s) \cup r, [Y] \rangle.\]
Thus (7) holds modulo the divisibility \( d(s) \) of \( s \); in particular, the “untwisted” Floer complex \( CF(Y, s; \mathbb{Z}) \) carries a relative cyclic grading by \( \mathbb{Z}/d(s)\mathbb{Z} \).

In light of these observations, henceforth we will assume that all modules for \( R_Y \) are graded, and often omit this assumption from statements. In particular, we will suppose that (7) holds at least modulo some \( d \in \mathbb{Z} \).

That the homology of \( CF^\infty(Y, s; M) \) is an invariant of \( (Y, s) \) follows by verifying that the arguments in [12; 11] respect the grading described here, together with the following.

**Lemma 3.3** The chain complex \( CF^\infty(Y, s; M) \), equipped with the relative grading defined above, is independent of the choice of additive assignment up to graded chain isomorphism.

**Proof** Suppose \( A_1 \) and \( A_2 \) are two additive assignments satisfying the criteria at the beginning of the previous section, and let \( \{ \theta_x \in \pi_2(x_0, x) \} \) be a complete set of paths for the spin\(^c \) structure \( s \). That is, \( x_0 \) is a fixed intersection point with \( s(x_0) = s \) and \( \theta_x \) is some choice of homotopy class for each \( x \in s^{-1}(s) \). Define a homomorphism \( F: CF^\infty(Y, s, A_1) \to CF^\infty(Y, s, A_2) \) between the chain complexes constructed with the two choices of assignment, by the formula

\[
F([x, i]) = e^{A_2(\theta_x) - A_1(\theta_x)}[x, i].
\]

Then

\[
F(\partial^\infty[x, i]) = \sum_{y, \phi} \#\widehat{M}(\phi)[y, i - n_z(\phi)] e^{A_1(\phi)} e^{A_2(\theta_y) - A_1(\theta_y)},
\]

while

\[
\partial^\infty F([x, i]) = \sum_{y, \phi} \#\widehat{M}(\phi)[y, i - n_z(\phi)] e^{A_2(\theta_y) - A_1(\theta_y)} e^{A_2(\phi)}.
\]

Now, for \( i = 1, 2 \) and given \( \phi \in \pi_2(x, y) \), we have \( \theta_x * \phi = \theta_y * P_\phi \) for a periodic domain \( P_\phi \in \pi_2(y, y) \) (up to addition of a multiple of the sphere class \([S]\), which does not affect the value of the additive assignment). Therefore by additivity

\[
A_i(\theta_x) + A_i(\phi) = A_i(\theta_y) + H(P_\phi)
\]

where \( H(P_\phi) \in H^1(Y; \mathbb{Z}) \) is the cohomology class corresponding to \( P_\phi \). It follows that the group ring elements appearing in the previous expressions are equal, so that \( F \) is a chain map. Since \( F \) is clearly an isomorphism of \( R_Y \)-modules, we get that \( CF^\infty(Y, s, A_1) \) and \( CF^\infty(Y, s, A_2) \) are isomorphic as ungraded \( R_Y \)-chain complexes.
To see invariance of the relative gradings, we calculate that
\[
\text{gr}_{A_2}(F([x, i], F([y, j]))) = \text{gr}_{A_2}([x, i], [y, j]) + \text{gr}_s(A_2(\theta_s) - A_1(\theta_s))
\]
\[
-\text{gr}_s(A_2(\theta_s) - A_1(\theta_s))
\]
\[
= \mu(\phi) + 2(i - j) - 2n_2(\phi) - (c_1(s) \cup A_2(\phi), [Y])
\]
\[
- (c_1(s) \cup (A_2(\theta_s) - A_1(\theta_s)), [Y])
\]
\[
+ (c_1(s) \cup (A_2(\theta_s) - A_1(\theta_s)), [Y])
\]

Applying the identity (8) twice, this easily reduces to \(\text{gr}_{A_1}([x, i], [y, j])\).

We now show that one can always work with relatively \(\mathbb{Z}\)-graded Floer homology (rather than groups with a finite cyclic grading) if the coefficient module and spin\(^c\) structure are induced by a cobordism from \(S^3\) to \(Y\). To do so we spell out the notion of a conjugate module in the current, graded, context. As usual, if \(Y\) is an oriented 3–manifold then \(-Y\) denotes the same manifold with the opposite orientation.

**Definition 3.4** Suppose \(M\) is a graded \(R_Y\)–module. The **conjugate module** \(\bar{M}\) is the graded \(R_{-Y}\) module whose underlying graded group is the same as \(M\), but whose multiplication is given by

\[
r \otimes m \mapsto \tilde{r} \cdot m, \quad r \in R_{-Y}.
\]

It is clear that if (7) is satisfied for \(M\) as a graded \(R_Y\)–module (modulo \(d\)), then the same is true for \(\bar{M}\) as a graded \(R_{-Y}\)–module.

**Proposition 3.5** Suppose \(W: S^3 \to Y\) is an oriented cobordism with spin\(^c\) structure \(s_W\), and \(M(W)\) is the induced module for \(R_Y\). Then \(M(W)\) carries a natural grading induced by \(s_W\) that is compatible with the \(s\)–grading on \(R_Y\) in the sense of (7), where \(s\) is the restriction of \(s_W\) to \(Y\). In particular, \(HF^0(Y, s; M(W))\) carries a relative \(\mathbb{Z}\) grading.

More generally, if \(W: Y_1 \to Y_2\) is an oriented cobordism with spin\(^c\) structure \(s_W\) whose restrictions to \(Y_1\) and \(Y_2\) are \(s_1\) and \(s_2\) respectively, and \(M\) is a module for \(R_{Y_1}\) satisfying (7) modulo \(d\), then the induced module \(M(W)\) carries a grading induced by \(s_W\) also satisfying (7) modulo \(d\).

**Proof** Observe first that since \(\partial W = -Y_1 \cup Y_2\), we should most naturally consider \(\mathbb{Z}[K(W)]\) as a module for \(R_{-Y_1}\) and \(R_{Y_2}\). Recall that \(M(W) = \bar{M} \otimes_{R_{-Y_1}} \mathbb{Z}[K(W)]\), where \(K(W) = \ker(H^2(W, \partial W) \to H^2(W))\). Define \(\text{gr}_W: K(W) \to \mathbb{Z}\) by

\[
\text{gr}_W(k) = -(c_1(s_W) \cup k, [W, \partial W])
\]
and use this to impose a grading \( \text{gr}_W \) on \( \mathbb{Z}[K(W)] \). We claim that this grading respects the action by \( R_{-Y_1} \) and \( R_{Y_2} \), where the latter are equipped with gradings coming from the restrictions of \( s_W \). To see this, it suffices to note that the actions of \( R_{-Y_1} \) and \( R_{Y_2} \) on \( \mathbb{Z}[K(W)] \) are induced by the coboundary maps \( \delta_i \): \( H^1(Y_i) \to K(W) \), and that

\[
c_1(s_W) \cup \delta_i r = \delta_i (j_i^* c_1(s_W) \cup r) = \delta_i(c_1(s_i) \cup r)
\]

where \( j_i: Y_i \to W, \ i = 1, 2 \) are the inclusions of the boundary components. Hence for \( r \in H^1(Y_1) \),

\[
\langle c_1(s_W) \cup \delta_1 r, [W, \partial W] \rangle = \langle c_1(s_1) \cup r, [-Y_1] \rangle
\]

and correspondingly for elements of \( H^1(Y_2) \).

\[\square\]

4 Pairings and duality

In [15], Ozsváth and Szabó defined a pairing

\[
\langle \cdot, \cdot \rangle: HF^+(Y, s; \mathbb{Z}) \otimes HF^-(Y, s; \mathbb{Z}) \to \mathbb{Z}
\]

on Floer homology, with respect to which cobordism-induced maps satisfy a certain duality. Here we extend this pairing to Floer homology with twisted coefficients and prove a corresponding duality; throughout we use the ring \( R_Y \) and modules \( M \) that are graded via some choice of spin\(^c\) structure on \( Y \) as in the previous section.

Recall that if \( (\Sigma, \alpha, \beta, z) \) is a pointed Heegaard diagram for \( Y \), then \( (-\Sigma, \alpha, \beta, z) \) describes the oppositely oriented manifold \( -Y \), and the map \( s_z \) is invariant under this change of orientation.

**Definition 4.1** Define a pairing

\[
\langle \cdot, \cdot \rangle: CF^\infty(Y, s; R_Y) \otimes_{R_Y} CF^\infty(-Y, s; R_{-Y}) \to R_Y
\]

as follows: for generators \( [x, i] \in CF^\infty(Y, s; R_Y) \) and \( [y, j] \in CF^\infty(-Y, s; R_{-Y}) \) set

\[
\langle [x, i], [y, j] \rangle = \begin{cases} 
1 & \text{if } x = y \text{ and } j = -i - 1 \\
0 & \text{otherwise}.
\end{cases}
\]

The desired pairing is obtained by extending by \( R_Y \)-linearity.

We must check that this definition has the desired properties:

*Geometry & Topology, Volume 12 (2008)*
Lemma 4.2 For any \( \xi \in CF^\infty(Y, s; R_Y) \), \( \eta \in CF^\infty(-Y, s; R_{-Y}) \), we have
\[
\langle \partial^\infty \xi, \eta \rangle = \langle \xi, \partial^\infty \eta \rangle
\]
\[
\langle U \xi, \eta \rangle = \langle \xi, U \eta \rangle.
\]

Proof This is much like the proof of the corresponding fact in untwisted Floer homology [15, Lemma 5.1], but we must be more careful with the coefficients. Observe that composition with the reflection \( r: D^2 \to D^2 \) across the real axis gives a map \( \pi_2(x, y) \to \pi_2(y, x) \) that exchanges \( J \)-holomorphic disks in \( \text{Sym}^g(\Sigma) \) with \( -J \)-holomorphic disks in \( \text{Sym}^g(-\Sigma) \); in other words
\[
M_{-\Sigma}(\phi \circ r) = M_{\Sigma}(\phi)
\]
for \( \phi \in \pi_2(x, y) \).

Furthermore, if \( A_Y \) is an additive assignment for \( (\Sigma, \alpha, \beta, z) \) then we can think of \( A_Y \) as also giving an additive assignment \( A_{-Y} \) for \( (-\Sigma, \alpha, \beta, z) \). For \( \phi \in \pi_2(x, y) \) we have that \( \phi \circ (\phi \circ r) \) is homotopic to a constant map, from which it follows that
\[
A_{-Y}(\phi \circ r) = -A_Y(\phi).
\]

Since \( n^{-\Sigma}_z(\phi) = n^{-\Sigma}_z(\phi \circ r) \), we have
\[
\partial^\infty[y, j] = \sum_{\phi \in \pi_2(y, w)} \#\hat{M}_{-\Sigma}(\phi)[w, j - n^{-\Sigma}_z(\phi)] \otimes e^{A_{-Y}(\phi)}
\]
\[
= \sum_{\phi \in \pi_2(w, y)} \#\hat{M}_{-\Sigma}(\phi \circ r)[w, j - n^{-\Sigma}_z(\phi \circ r)] \otimes e^{A_{-Y}(\phi \circ r)}
\]
\[
= \sum_{\tilde{\phi} \in \tilde{\pi}_2(w, y)} \#\hat{M}_{\tilde{\Sigma}}(\tilde{\phi})[w, j - n^{-\tilde{\Sigma}}_z(\tilde{\phi})] \otimes e^{-A_Y(\tilde{\phi})}.
\]

From this it follows (using the conjugate module structure on the second factor) that
\[
\langle [x, i], \partial^\infty[y, j] \rangle = \sum_{\phi \in \pi_2(x, y)} \#\hat{M}(\phi) e^{A_Y(\phi)}
\]
\[
= \sum_{\mu = 1}^{\infty} \sum_{\n = i + j + 1}^{\infty} \hat{M}(\phi) \cdot \langle \partial^\infty[x, i], [y, j] \rangle.
\]

The first claim of the lemma follows from this, while the second is obvious. \( \square \)

Thus we obtain a pairing on homology
\[
HF^+(Y, s; R_Y) \otimes_{R_Y} HF^-(Y, s; R_{-Y}) \to R_Y
\]
that descends to the reduced homologies.

More generally, suppose $M$ and $N$ are (graded) modules for $R_Y$ and $R_{-Y}$, respectively: we can extend the construction above to a pairing between $HF^+(-Y, s; M)$ and $HF^+(-Y, s; N)$. To this end, define

$$
\langle \cdot, \cdot \rangle : CF^\infty(Y, s; M) \otimes_{R_Y} CF^\infty(-Y, s; N) \to M \otimes_{R_Y} N
$$

on generators by

$$
\langle [x, i] \otimes m, [y, j] \otimes n \rangle = ([x, i], [y, j]) \cdot m \otimes n.
$$

where the pairing on the right is the universal one just defined. It follows from the calculation above that the pairing descends to homology:

$$
HF^+(Y, s; M) \otimes_{R_Y} HF^+(-Y, s; N) \to M \otimes_{R_Y} N.
$$

We can now give the analogue for twisted coefficients of Theorem 3.5 of [15].

**Theorem 4.3** (Duality for twisted coefficients) Let $W : Y_1 \to Y_2$ be a cobordism and $M_1$ and $M_2$ coefficient modules for $R_{Y_1}$ and $R_{Y_2}$ respectively. Write $W'$ for the manifold $W$ regarded as a cobordism $-Y_2 \to -Y_1$, and let $s$ be a spin$^c$ structure on $W$ with restrictions $s_i = s|_{Y_i}$. Then for any $\xi \in HF^+(Y_1, s_1; M_1)$ and $\eta \in HF^+(-Y_2, s_2; M_2)$, we have

$$
\langle F^+_{\bar{W}, s}(\xi), \eta \rangle = \langle \xi, F^{-}_{\bar{W}', s}(\eta) \rangle.
$$

Observe that the two pairings in the theorem above take values in

$$
M_1(W) \otimes_{R_{Y_2}} M_2 = M_1 \otimes_{R_{-Y_1}} \mathbb{Z}[K(W)] \otimes_{R_{Y_2}} M_2
$$

(for the left hand side) and

$$
M_1 \otimes_{R_{Y_1}} M_2(W) = M_1 \otimes_{R_{Y_1}} \mathbb{Z}[K(W)] \otimes_{R_{Y_2}} M_2 = M_1 \otimes_{R_{Y_1}} \mathbb{Z}[K(W)] \otimes_{R_{-Y_2}} M_2,
$$

(for the right). Thus the two target groups are identical (with conjugate module structures), and the equality of the theorem makes sense.

**Proof** We adapt the proof from [15]. Decompose $W$ into a composition of 1–handle additions, followed by 2–handles and then 3–handles. The verification of duality for
1– and 3–handle cobordisms is unchanged from the untwisted case given in [15], so we omit it here.

Assume, then, that \( W \) is a cobordism comprised entirely of 2–handle additions. Let \( R \) denote the reflection of the standard 2–simplex \( \Delta \) that fixes one corner and exchanges the other two. Specifically, if the edges are labeled \( e_\alpha, e_\beta \) and \( e_\gamma \), we take \( R \) to exchange \( e_\beta \) and \( e_\gamma \) while reversing \( e_\alpha \). If \( A_W \) is an additive assignment for a Heegaard triple \((\Sigma, \alpha, \beta, \gamma, z)\) associated to \( W \) as in Definition 2.5 (using a base triangle \( \psi_0 \)), then we obtain an additive assignment \( A_W' \) for \( W' \) (described by the triple \( (-\Sigma, \alpha, \gamma, \beta, z) \)) from the triangle \( \psi_0 \circ R \).

More generally, for any (homotopy class of) triangle \( \psi \in \pi_2(x, y, w) \), precomposition with \( R \) gives a triangle \( \psi \circ R \in \pi_2(w, y, x) \). Moreover, if \( \psi = \psi_0 + \phi_{\alpha\gamma} + \phi_{\beta\gamma} + \phi_{\alpha\beta} \) then it is easy to see that

\[
\psi \circ R = \psi_0 \circ R + (\phi_{\alpha\gamma} \circ r) + \phi_{\gamma\beta} + (\phi_{\alpha\beta} \circ r),
\]

where \( r \) is the reflection across the real axis used previously. Therefore

\[
A_W' (\psi \circ R) = \delta (-A_{-\gamma_2} (\phi_{\alpha\gamma} \circ r) + A_{-\gamma_1} (\phi_{\alpha\beta} \circ r)) = A_W (\psi)
\]

(cf the proof of Lemma 4.2). Furthermore, just as in the case of disks we have an identification

\[
\mathcal{M}_{-\Sigma} (\psi \circ R) = \mathcal{M}_{\Sigma} (\psi).
\]

Thus for \( m_i \in M_1 \):

\[
\langle F_{m_i}, [x, i]m_1, [w, k]m_2 \rangle = \sum_{\psi \in \pi_2(x, \Theta, x)} \sum_{v \in T_\alpha \cap T_\gamma} \sum_{\psi \in \pi_2(x, \Theta, v)} \#M_{\Sigma} (\psi) \cdot [v, i - n_z (\psi)]m_1 \otimes e^{A_W (\psi)},
\]

\[
[w, k]m_2
\]

\[
= \sum_{\psi \in \pi_2(x, \Theta, w)} \sum_{n_z (\psi) = i + k + 1} \#M_{\Sigma} (\psi) \cdot (m_1 \otimes e^{A_W (\psi)}) \otimes m_2,
\]

an element of \( M_1 (W) \otimes \overline{M}_2 \) (where all sums are over triangles with Maslov index 0).

*Geometry & Topology, Volume 12 (2008)*
On the other hand, in $M_1 \otimes M_2(W)$.

$$\langle [x, i]m_1, F_{W, s}( [w, k]m_2) \rangle = \left\langle [x, i]m_1, \right.$$ 

$$\sum_{\psi \in \pi_2(w, \Theta, v)} \#M_{\Sigma}(\bar{\psi}) \cdot [v, k - n_z(\bar{\psi})]m_2 \otimes e^{A_{W, s}(\bar{\psi})} \right\rangle$$

$$= \sum_{\psi \in \pi_2(w, \Theta, x)} \#M_{\Sigma}(\psi \circ R) \cdot m_1 \otimes (m_2 \otimes e^{A_{W, s}(\psi \circ R)})$$

$$= \sum_{\psi \in \pi_2(w, \Theta, x)} \#M_{\Sigma}(\psi \circ R) \cdot m_1 \otimes (m_2 \otimes e^{A_{W, s}(\psi)}) \quad \Box$$

5 Action of first homology

In this section we extend to twisted coefficients an additional aspect of the algebraic structure of Heegaard Floer homology, namely the action of $\Lambda^*(H_1(Y)/\text{tors})$ on $HF^*(Y, s)$. We also discuss the interaction of this structure with cobordism-induced homomorphisms. Much of this section is a straightforward generalization of material from [12; 11; 15], so we omit many of the details.

**Proposition 5.1** Fix an oriented spin$^c$ 3–manifold $(Y, s)$ and a module $M$ for $R_Y = \mathbb{Z}[H_1(Y)]$. Then for any $h \in H_1(Y)/\text{tors}$ there is a chain endomorphism $A_h$ of $CF^\infty(Y, s; M)$ of degree $-1$, equivariant with respect to $U$ and the $R_Y$ action, with the property that $A_h \circ A_h$ is chain homotopic to 0.

Thus, the collection of maps $A_h$ provides $HF^*(Y, s; M)$ with the structure of a module over $R_Y[U] \otimes \Lambda^*(H_1(Y)/\text{tors})$.

**Proof** For a generator $[x, i] \otimes m \in CF^\infty(Y, s; M)$ we set

$$A_h([x, i] \otimes m) = \sum_{y \in T_0 \cap T_{10}} \sum_{\phi \in \pi_2(x, y)} \#M(\phi)(A(\phi), h) \cdot [y, i - n_z(\phi)] \otimes e^{A(\phi) \cdot m}.$$

*Geometry & Topology, Volume 12 (2008)*
Then the proof that $A_h$ is a chain map whose square is trivial in homology is virtually identical to the proof in the untwisted case (cf Proposition 4.17 of [12]), and it is straightforward to check that the action of $A_h$ on homology is independent of the choice of additive assignment $A$ (cf the proof of Lemma 3.3).

We will omit the map $A_h$ from the notation and simply write $h \cdot \xi$ for the action of $h$ on the element $\xi \in HF^0(Y, s; M)$.

**Remark 5.2** Though the action of $H_1(Y)_{\text{tors}}$ is defined for Floer homology with any coefficients, it may be largely trivial. Indeed, suppose $M$ is an $R_Y$–module, and let $Z_M \subset H^1(Y)$ denote the stabilizer of $M$: that is, the set of all $\alpha \in H^1(Y)$ such that $\alpha m = m$ for all $m \in M$. Then it can be shown that if $h \in H_1(Y)$ has the property

$$\langle \alpha, h \rangle = 0 \text{ for all } \alpha \in Z_M,$$

then $A_h$ is chain homotopic to 0. In particular, this implies that the $H_1(Y)_{\text{tors}}$ action on the fully twisted homology $HF^0(Y, s; R_Y)$ is trivial.

**Lemma 5.3** Let $(Y, s)$ be as above, and let $M$ and $N$ be modules for $R_Y$ and $R_{-Y}$ respectively. Then for any $h \in H_1(Y)_{\text{tors}}$, any $\xi \in HF^+(Y, s; M)$ and any $\eta \in HF^-(Y, s; N)$ we have

$$\langle h \cdot \xi, \eta \rangle = -\langle \xi, h \cdot \eta \rangle.$$

**Proof** This follows from a calculation very similar to the one in Lemma 4.2. Indeed, the only difference is the appearance of the factors $\langle A(\phi), h \rangle$, which change sign under orientation reversal.

We now extend the twisted cobordism invariants from the previous section to include the action of first homology. Specifically, for a cobordism $W: Y_0 \to Y_1$ we wish to define $F_{W,0}^\circ$ as a map

$$F_{W,0}^\circ: HF^0(Y_0, s_0; M) \otimes \Lambda^* H_1(W)_{\text{tors}} \to HF^0(Y_1, s_1; M(W)),$$

With the preceding in place the definition runs precisely as in the untwisted case in [15]; we summarize the construction.

Suppose first that $W: Y_0 \to Y_1$ is a cobordism consisting only of 2–handle additions. Then it is easy to see that the map

$$i_* = i_{0*} - i_{1*}: H_1(Y_0)_{\text{tors}} \oplus H_1(Y_1)_{\text{tors}} \to H_1(W)_{\text{tors}}$$

in

*Geometry & Topology, Volume 12 (2008)*.
we set

!

Let

Theorem 5.4

properties of the original ones. We mention two results here.

Many properties of the extended cobordism maps (9) follow from corresponding properties of the original ones. We mention two results here.

Theorem 5.4 Let \( W: Y_0 \to Y_1 \) be a cobordism with spin\(^c\) structure \( s \) and suppose \( \omega \in \Lambda^* H_1(W)/\text{tors} \). Write \( s_i \) for \( s|_{Y_i} \). Then for modules \( M \) and \( N \) over \( R_{Y_0} \) and \( R_{Y_1} \) respectively, and for any \( x \in HF^+(Y_0, s_0; M) \) and \( y \in HF^-(Y_1, s_1; N) \), we have

\[
\langle F^+_W(x \otimes \omega), y \rangle = \langle x, F^-_{W,s}(y \otimes \omega) \rangle.
\]

Proof Assume first that \( W \) consists of 2–handles only, and suppose \( h \in H_1(W)/\text{tors} \) has the expression \( h = i_s(h_0, h_1) \) for \( h_i \in H_1(Y_i)/\text{tors} \). Then using the duality theorem for twisted coefficients (Theorem 4.3) and Lemma 5.3 we have

\[
\langle F^+_W(x \otimes h), y \rangle = \langle F^+_W(h_0 \cdot x) - h_1 \cdot F^+_W(x), y \rangle
\]

\[
= -(x, h_0 \cdot F^-_{W,s}(y)) + \langle x, F^-_{W,s}(h_1 \cdot y) \rangle
\]

\[
= \langle x, F^-_{W,s}(y \otimes h) \rangle.
\]

It is a simple matter to extend to general cobordisms and general \( \omega \).
Theorem 5.5  The composition law (Theorem 2.9) holds for the extended maps (9). More precisely, suppose $W = W_1 \cup_{Y_1} W_2$ is a composite cobordism and write

$$j_*: \Lambda^*(H_1(W_1)/\text{tors}) \otimes \Lambda^*(H_1(W_2)/\text{tors}) \rightarrow \Lambda^*(H_1(W)/\text{tors})$$

for the surjection induced on exterior algebras by the Mayer–Vietoris map $H_1(W_1) \oplus H_1(W_2) \rightarrow H_1(W)$. Fix $\omega_i \in \Lambda^*H_1(W_i)/\text{tors}$ and write $\omega$ for the image of $\omega_1 \otimes \omega_2$ under $j_*$. Then for any spin$^c$ structure $s$ on $W$, we can find choices of representatives for the maps $F^{\circ}$ such that for any $\alpha \in H^1(Y_1)$

$$F_{W,s-\delta\alpha}^{\circ}(\xi \otimes \omega) = \Pi_W \left[ F_{W_2,s\mid W_2}^{\circ} \left( e^{\alpha} \cdot F_{W_1,s\mid W_1}^{\circ}(\xi \otimes \omega_1) \otimes \omega_2 \right) \right].$$

Proof  This follows from Theorem 2.9 together with the formal properties of the $H_1$–action, particularly (10) in the case of 2–handles. (See Ozsváth–Szabó [15], particularly Proposition 4.20. Note that here the strengthened composition law means that summing over spin$^c$ structures is unnecessary.)

6 Conjugation and orientation reversal

As in the original Heegaard Floer theory, there are simple relationships between the twisted Heegaard Floer homologies of $(Y,s)$, $(-Y,s)$, and $(Y,\bar{s})$, where $\bar{s}$ is the conjugate spin$^c$ structure. To describe the effect of spin$^c$ conjugation, recall that though we normally do not include it in the notation, the ring $R_Y$ depends on $s$ through the grading (5), and here we write $R_{Y,s}$ to indicate this. Thus $R_{Y,s}$ and $R_{Y,\bar{s}}$ are identical rings with opposite gradings; in fact $R_{Y,\bar{s}} = R_{-Y,s}$ as graded rings. In particular, if $M$ is a graded module for $R_{Y,s}$, the conjugate module $\bar{M}$ can be considered either as a module for $R_{-Y,s}$ or for $R_{Y,\bar{s}}$.

Theorem 6.1  If $(Y,s)$ is a closed spin$^c$ 3–manifold and $M$ is a module for $R_{Y,s}$, then there is a grading–preserving isomorphism of $R_{Y,s}$–modules

$$J: HF^{\circ}(Y,s;M) \rightarrow HF^{\circ}(Y,\bar{s};\bar{M}).$$

Proof  We mimic the argument in the untwisted case [11, Theorem 2.4]. Recall that if $(\Sigma,\alpha,\beta,z)$ is a Heegaard diagram for $Y$ and $x \in T_\alpha \cap T_\beta$ has $s_z(x) = s$, then $(-\Sigma,\beta,\alpha,z)$ also describes $Y$, and in this diagram $s_z(x) = \bar{s}$. If $\{A_{x,y}\}$ is an additive assignment for $(\Sigma,\alpha,\beta,z)$, then we obtain an assignment $A'$ for $(-\Sigma,\beta,\alpha,z)$ by $A'_{x,y}(\phi) = -A_{x,y}(\phi \circ f)$, where $f$ is the reflection across the imaginary axis in $\mathbb{C}$.

Define a homomorphism $J: CF^{\circ}(Y,s;R_{Y,s}) \rightarrow CF^{\circ}(Y,\bar{s};R_{Y,\bar{s}})$ by mapping $[x,i]$ in the diagram $(\Sigma,\alpha,\beta,z)$ to $[x,i]$ in the diagram $(-\Sigma,\beta,\alpha,z)$ and extending.
by $\mathbb{Z}[H^1(Y)]$–antilinearity. Then it is a straightforward exercise to check that $J$ is a chain map preserving relative gradings, recalling that $M_\Sigma(\phi \circ f) = M_\Sigma(\phi)$, $n_\Sigma^\pm(\phi \circ f) = n_\Sigma^\pm(\phi)$, and $\mu_\Sigma(\phi \circ f) = \mu_\Sigma(\phi)$. In general,

$$J : CF^\bullet(Y, s) \otimes_{R_Y, s} M \to CF^\bullet(Y, \bar{s}) \otimes_{R_Y, \bar{s}} \bar{M}$$

is given by $[x, i] \otimes m \mapsto [x, i] \otimes m$. Since this is an antilinear chain isomorphism, the theorem follows.

It is not hard to generalize the naturality of cobordism-induced maps under conjugation to the twisted case.

Before describing the effect of orientation reversal, we pause to spell out our duality conventions. Let $M$ be a graded $R_{Y, s}$–module, and set

$$CF^*_0(Y, s; M) = \text{Hom}_{R_{Y, s}}(CF^*_0(Y, s), M),$$

made into an $R_{Y, s}$–module in the obvious way. For the grading, suppose $\alpha, \beta \in CF^*_0(Y, s; M)$ are homogeneous (as homomorphisms between relatively graded $R_{Y, s}$–modules). Set

$$\text{gr}_{CF^*}(\alpha, \beta) = \text{gr}_M(\alpha(f)) - \text{gr}_M(\beta(g)) - \text{gr}_{CF_*}(f, g)$$

for any homogeneous $f, g \in CF^*_0(Y, s)$ with $\alpha(f)$ and $\beta(f)$ nonzero in $M$. Thus, for example, $\text{gr}_{CF^*}(r\alpha, \alpha) = \text{gr}_s(r)$ for $r \in R_{Y, s}$.

Observe that there is a natural generating set for $CF^\infty_0(Y, s; R_{Y, s})$. Namely, for a generator $[x, i] \in CF^\infty_0(Y, s)$, define $[x, i]^* : CF^\infty_0(Y, s) \to R_{Y, s}$ by setting $[x, i]^*([y, j] \otimes r) = r$ if $[y, j] = [x, i]$, and 0 otherwise. Since $CF^\infty_0(Y, s)$ is a free complex over $R_{Y, s}$, elements of $CF^\infty_0(Y, s; M)$ can be expressed as combinations of elements of the form $[x, i]^* \otimes m$, whose value on $[y, j]$ is $[x, i]^*([y, j]) \cdot m$.

In terms of these generators, the coboundary in $CF^*$ can be expressed explicitly by

$$\delta([x, i]^* \otimes m) = \sum_{\phi \in \pi_2(y, x)} \#\tilde{M}(\phi)[y, i + n_\Sigma(\phi)]^* \otimes e^A(\phi)m.$$ 

With the grading conventions outlined above, we have

$$\text{gr}_{CF^*(Y)}([x, i]^*, [y, j]^*) = -\text{gr}_{CF^*(Y)}([x, i], [y, j]).$$

Observe that with these conventions, the codifferential has degree $-1$, in other words, $CF^\infty_0(Y, s; M)$ is a chain complex rather than a cochain complex. Likewise, the transpose action of $U$ given by $U : [x, i]^* \mapsto [x, i + 1]^*$ decreases grading by 2.
Theorem 6.2  For \((Y, s)\) a closed spin\(^c\) 3–manifold and \(M\) a module for \(R_{Y, s}\), there is a grading-preserving isomorphism of \(R_{Y, s}\)–modules

\[
HF^\pm_*(Y, s; M) \cong HF^*_{-\mp}(-Y, s; \bar{M}).
\]

Proof  Just as in the proof in [11, Proposition 2.5], define a homomorphism

\[
CF^\circ_* (Y, s; M) \rightarrow CF^*_{-\circ}(-Y, s; \bar{M})
\]

by \([x, i] \otimes m \mapsto [x, -1 - i]^* \otimes m\), where on the right we consider \(m\) as an element of \(\bar{M}\). One checks easily that this gives rise to a \(\mathbb{Z}[H^1(Y)]\)–antilinear chain isomorphism that preserves relative grading.

\[
\square
\]

7  Invariants for 4–manifolds

We briefly recall the definition of Ozsváth–Szabó 4–manifold invariants from [15], and then proceed to discuss their calculation in the context of 4–manifolds obtained by gluing two manifolds with boundary.

Suppose \(X\) is a closed 4–manifold having \(b^+(X) \geq 2\). Then we can find an admissible cut for \(X\): that is, a hypersurface \(N \subset X\) separating \(X\) into components \(X = V_1 \cup_N V_2\) with the following properties:

(1)  For \(i = 1, 2\), we have \(b^+(V_i) \geq 1\).

(2)  The image of the Mayer–Vietoris map \(\delta: H^1(N) \rightarrow H^2(X)\) is trivial.

As observed previously (Remark 2.8), the second condition ensures that spin\(^c\) structures on \(X\) are determined by their restrictions to \(V_1\) and \(V_2\).

The first condition is relevant because of the following.

Lemma 7.1  [15]  If \(W\) is a cobordism having \(b^+(W) \geq 1\) then for any spin\(^c\) structure \(s\) and in any coefficient module, the map \(F^\infty_{W, s}\) vanishes.

Recall that for all sufficiently large integers \(r\), the subgroups \(\ker(U^+_r) \subset HF^-(Y, s)\) and \(\im(U^+_r) \subset HF^+(Y, s)\) are independent of \(r\) (where \(U^\pm\) denotes the action of \(U\) on \(HF^\pm\)). The reduced Floer homology groups are defined by \(HF^\text{red}_-(Y, s) = \ker(U^+_r)\) and \(HF^\text{red}_+(Y, s) = \coker(U^+_r)\). Together with the long exact sequence

\[
\cdots \rightarrow HF^\infty(Y, s) \rightarrow HF^+(Y, s) \rightarrow \eta \rightarrow HF^-(Y, s) \rightarrow \cdots
\]

\(\text{Geometry & Topology, Volume 12 (2008)}\)
and the fact that $U$ is an isomorphism on $HF^\infty$, Lemma 7.1 implies that the image of $F^-_{W,s}$ for $W$ a cobordism with $b^+(W) \geq 1$ lies in $HF^-_{\text{red}}$, while $F^+_{W,s}$ factors through $HF^+_{\text{red}}$. Note also that the homomorphism $\tau$ in the sequence induces an isomorphism

$$\tau: HF^+_{\text{red}}(Y, s) \to HF^-_{\text{red}}(Y, s).$$

(All of the above holds in any coefficient system).

**Definition 7.2** [15] Let $\Theta^-$ denote a top-degree generator of $HF^-(S^3)$. Let $N$ be an admissible cut for a 4–manifold $X$ as above, and fix a spin$^c$ structure $s$ on $X$. The **Ozsváth–Szabó invariant** of $(X, s)$ is the integer-valued function

$$\Phi_{X,s}: \Lambda(X) := \mathbb{Z}[U] \otimes \Lambda^*(H_1(X)/\text{tors}) \to \mathbb{Z}/\pm 1$$

defined by

$$\Phi_{X,s}(U^n \otimes \omega) = ((F^+_2 \circ \tau^{-1} \circ F^+_1)(U^n \cdot \Theta^- \otimes \omega), \Theta^-).$$

Note that $\Phi_{X,s}$ is defined only modulo a sign, due to the sign ambiguity of the maps associated to cobordisms.

**Remark 7.3** As a slight abuse of notation, if $Z$ is a 4–manifold with one boundary component $Y$, and $s$ is a spin$^c$ structure on $Z$, we will denote by $F^o_{Z,s}$ the homomorphism $HF^o(S^3) \to HF^o(Y)$ induced by the cobordism obtained by removing a 4–ball from the interior of $Z$.

**Remark 7.4** It follows from the formula for the degree shift induced by a cobordism that $\Phi_{X,s}$ is nonzero only on elements of $\Lambda(X)$ having degree $d(s)$, where

$$d(s) = \frac{1}{4}(c_2(s) - 2e(X) - 3\sigma(X)).$$

Here $e(X)$ is the Euler characteristic of $X$ and $\sigma(X)$ is the signature, and $\Lambda(X)$ is graded so that $U$ carries degree 2 and elements of $H_1(X)/\text{tors}$ carry degree 1.

Ozsváth and Szabó show that $\Phi_{X,s}$ does not depend on the choice of admissible cut $N$, and therefore gives an invariant of smooth spin$^c$ 4–manifolds with $b^+ \geq 2$. An important property of $\Phi_{X,s}$ is that it is nonzero for at most finitely many spin$^c$ structures $s$ on $X$.

In many situations there are convenient decompositions $X = Z_1 \cup_Y Z_2$, in which $Y$ fails to be admissible in the sense above—specifically, condition (2) in the definition of admissibility is violated. Ozsváth and Szabó prove that one can use such a cut to
obtain information about sums of invariants of \( X \) (Lemma 8.8 of [15]), but in order to obtain more detailed information we must pass to twisted coefficients.

We express our results in terms of group rings. In the situation of cutting \( X \) along a 3–manifold \( Y \) satisfying (1) but not (2) in the definition of admissible cut, the relevant group is \( K(X, Y) = \ker(H^2(X) \to H^2(Z_1) \oplus H^2(Z_2)) \) (cf Remark 2.8). For a given \( s \in \text{Spin}^c(X) \) and \( \alpha \in \Lambda(X) \), we would like a way to calculate the element

\[
\sum_{t \in K(X, Y)} \Phi_{X, s+t}(\alpha) \cdot e^t \in \mathbb{Z}[K(X, Y)]
\]

in terms of invariants on the manifolds-with-boundary \( Z_1 \) and \( Z_2 \). Indeed, the invariants of all \text{spin}^c structures on \( X \) can be read from the coefficients of the above expressions for various \( s \).

Since we need to refer to maps in both twisted and untwisted Floer homology, in this section we will follow the notation of Ozsváth and Szabó and write \( F_W \) for the map in twisted coefficients induced by \( W \) and \( F^o_W \) for the untwisted map.

**Definition 7.5** Suppose \( Z \) is an oriented 4–manifold with connected boundary \( \partial Z = Y \) and \( s \in \text{Spin}^c(Z) \). Define the relative Ozsváth–Szabó invariant \( \Psi_{Z,s} \) of \( Z \) to be the function

\[
\Psi_{Z,s} : \Lambda(Z) \to HF^{-}(Y, s|_Y; \mathbb{Z}[K(Z)])/K(Z)
\]

given by

\[
\Psi_{Z,s}(U^n \otimes \omega) = [F^{-}_{Z,s}(U^n \cdot \Theta^{-} \otimes \omega)].
\]

Here the brackets indicate equivalence class under the action of \( K(Z) \), where \( K(Z) = \ker(H^2(Z, Y) \to H^2(Z)) \).

Normally we will think of \( \Psi_{Z,s} \) as an honest function with values in \( HF^{-}(Y) \) by choosing a representative for the equivalence class (though strictly, the twisted-coefficient map \( F^{-}_{Z,s} \) is defined only up to sign and the action of \( \delta(H^1(\partial Z)) = K(Z) \)). Note also that if \( b^+(Z) \geq 1 \) then \( \Psi_{Z,s} \) takes values in \( HF^{-}_{\text{red}}(Y) \).

The following result gives the central statement of Theorem 1.5 from the introduction, and shows how to calculate (11) in terms of relative invariants.

**Theorem 7.6** Let \( X \) be a closed 4–manifold with \( b^+(X) \geq 2 \) and \( Y \subset X \) a 3–dimensional submanifold separating \( X \) into components \( Z_1 \) and \( Z_2 \). Let \( s \) be a \text{spin}^c structure on \( X \) and write \( s_i = s|_{Z_i} \). Assume that \( \Psi_{Z_1,s_i} \) takes values in \( HF^{-}_{\text{red}} \) for
\(i = 1, 2,\) and also that \(b^+(Z_i) \geq 1\) for at least one of \(Z_1, Z_2\). Then for any \(\alpha_i \in \mathcal{A}(Z_i)\) we have
\[
\sum_{t \in K(X, Y)} \Phi_{X, \alpha + t}(\alpha) \cdot e^t = (\tau^{-1}(\Psi_{Z_1, s_1}(\alpha_1)), \Psi_{Z_2, s_2}(\alpha_2))
\]
as elements of \(\mathbb{Z}[K(X, Y)]\), up to sign and multiplication by an element of \(K(X, Y)\). Here \(\alpha\) is the image of \(\alpha_1 \otimes \alpha_2\) under the natural map \(\mathcal{A}(Z_1) \otimes \mathcal{A}(Z_2) \to \mathcal{A}(X)\).

In the statement of the theorem, we are implicitly choosing representatives for \(\Psi_{Z_i, s_i}(\alpha_i)\) and pairing them using the twisted-coefficient pairing defined earlier. Lemma 2.7 shows that the pairing does indeed take values in \(\mathbb{Z}[K(X, Y)]\), and it follows also that different choices of representatives give rise to elements of \(\mathbb{Z}[K(X, Y)]\) differing by multiplication by an element of \(K(X, Y)\).

The rest of this section is devoted to the proof of Theorem 7.6. For simplicity, we focus on the case \(\alpha = 0\) in the following; the general case follows by an entirely analogous argument with Theorem 5.4 and Theorem 5.5 replacing Theorem 4.3 and Theorem 2.9.

We begin with a few easy preparatory lemmas.

**Lemma 7.7** Fix a spin\(^c\) 3–manifold \(Y\) and \(R_Y\)–modules \(M\) and \(N\). Let \(\phi: M \to N\) be a module homomorphism, and write \(\phi_*: HF^c(Y; M) \to HF^c(Y; N)\) for the induced map in Floer homology. Then the following diagram commutes:
\[
\begin{array}{ccc}
HF^-(Y; M) & \to & HF^c(Y; M) & \to & HF^+(Y; M) \\
\downarrow \phi & & \downarrow \phi & & \downarrow \phi \\
HF^-(Y; N) & \to & HF^c(Y; N) & \to & HF^+(Y; N)
\end{array}
\]
In particular, \(\phi_*\) descends to a map on reduced homology, and commutes with \(\tau\) (and \(\tau^{-1}\)).

**Proof** This is clear.

**Lemma 7.8** For \(i = 1, 2\) let \(M_i\) and \(N_i\) be modules for \(R_Y\) and \(R_{-Y}\) respectively, and consider homomorphisms \(\phi: M_1 \to M_2\) and \(\psi: N_1 \to N_2\). For any \(\xi \in HF^+(Y; M_1)\) and \(\eta \in HF^-(Y; N_1)\), we have
\[
(\phi_*(\xi), \psi_*(\eta)) = \phi \otimes \psi((\xi, \eta)) \in M_2 \otimes_{R_Y} N_2.
\]

**Proof** This follows easily from the definitions.
Lemma 7.9 Suppose \( W = W_1 \cup Y_1 W_2; Y_0 \to Y_2 \) is a composite cobordism, and \( s_1 \) and \( s_2 \) are spin\(^c\) structures on \( W_1 \) and \( W_2 \) with \( s_1|_{Y_1} = s_2|_{Y_1} \). If \( F^-_{W_1,s_1} \) has image in \( HF^-_{red}(Y_1) \) then for any coefficient module \( M \) for \( Y_0 \),

1. \( \text{im}(F^-_{W_2,s_2} \circ F^-_{W_1,s_1}) \subset HF^-_{red}(Y_2; M(W_1)(W_2)), \) and
2. \( \tau^{-1} \circ F^-_{W_2,s_2} \circ F^-_{W_1,s_1} = F^+_{W_2,s_2} \circ \tau^{-1} \circ F^-_{W_1,s_1}. \)

Proof Point (1) is clear from the fact that \( F^-_{W_2,s_2} \) maps \( HF^-_{red}(Y_1; M(W_1)) \) into \( HF^-_{red}(Y_2; M(W_1)(W_2)) \).

Statement (2) follows from the commutative diagram

\[
\begin{array}{ccc}
HF^+(Y_1; M(W_1)) & \xrightarrow{F^+_{W_2,s_2}} & HF^+(Y_2; M(W_1)(W_2)) \\
\tau & & \tau \\
HF^-(Y_0; M) & \xrightarrow{F^-_{W_1,s_1}} & HF^-(Y_1; M(W_1)) \xrightarrow{F^-_{W_2,s_2}} HF^-(Y_2; M(W_1)(W_2))
\end{array}
\]

together with part (1).

With these preliminaries in place, we turn our attention to the proof of Theorem 7.6 (with \( \alpha_1 = \alpha_2 = \alpha = 1 \)). Thus, let \( X = Z_1 \cup_Y Z_2 \) be as in the statement of the theorem, and let us assume \( b^+(Z_2) \geq 1 \). Then we can find an admissible cut \( N \) for \( X \) contained in \( Z_2 \) (cf the construction in example 8.4 of [15]). Suppose \( X \) is decomposed into pieces \( V_1 \) and \( V_2 \) along \( N \), so that

\[ X = V_1 \cup_Z V_2 = Z_1 \cup_Y W \cup_N V_2 \]

where \( W = V_1 \cap Z_2 \) is a cobordism \( Y \to N \).

Let us fix a spin\(^c\) structure \( s \) on \( X \). For simplicity we will omit the spin\(^c\) structure from the notation for homomorphisms induced by cobordisms, but all relevant cobordisms and their boundaries will be equipped with spin\(^c\) structures obtained by restricting \( s \).

By definition, we have

\[
\Phi_{X,s}(1) = \langle F^+_V \circ \tau^{-1} \circ F^-_{V_1}(\Theta^-), \Theta^- \rangle \\
= \langle \tau^{-1} \circ F^-_{V_1}(\Theta^-), F^-_{V_2}(\Theta^-) \rangle \\
= \langle \tau^{-1} \circ \varepsilon_* \circ F^-_{V_1}(\Theta^-), \varepsilon_* \circ F^-_{V_2}(\Theta^-) \rangle \\
= \langle \tau^{-1} \circ F^-_{V_1}(\Theta^-), F^-_{V_2}(\Theta^-) \rangle.
\]

(13)
We have passed to twisted coefficients using the remark after Theorem 2.9. The last line uses Lemma 7.7 and the twisted pairing which takes values in $\mathbb{Z}[K(X, N)]$. Since $N$ is admissible the group $K(X, N)$ is trivial and hence the pairing is $\mathbb{Z}$–valued; the homomorphism $\epsilon_* \otimes \epsilon_*$ arising from Lemma 7.8 is the identity here.

According to Theorem 2.9 we can find representatives for the maps involved that satisfy

$$F_{V_1} = \Pi_{V_1} \circ F_{W} \circ F_{Z_1},$$

where $\Pi_{V_1}$ is the map induced in homology by a projection map $\mathbb{Z}[K(V_1, Y)] \to \mathbb{Z}[K(V_1)]$, which we also denote by $\Pi_{V_1}$. Different choices of representatives for $[F_{V_1}]$ and the other maps differ by the action of $R_N$ on $\mathbb{Z}[K(X, N)] = \mathbb{Z}$, which is trivial. Hence we can replace (13) with

$$\hat{X}, s_{1/2} \cdot (\tau^{-1} \circ \Pi_{V_1} \circ F_{W} \circ F_{Z_1}(\Theta^-), F_{V_2}(\Theta^-)).$$

(14)

**Lemma 7.10** Under the isomorphism $\mathbb{Z}[K(V_1, Y)] \otimes_{R_N} \mathbb{Z}[K(V_2)] \cong \mathbb{Z} \left[ \frac{K(V_1, Y) \oplus K(V_2)}{H^1(N)} \right]$, the map $\Pi_{V_1} \otimes 1$ corresponds to the homomorphism $\Pi_{Z}$ sending an element of a group ring to the coefficient of the identity element.

**Proof** We have a diagram of identifications:

$$\begin{array}{ccc}
\mathbb{Z}[K(V_1, Y)] \otimes_{R_N} \mathbb{Z}[K(V_2)] & \xrightarrow{\Pi_{V_1} \otimes 1} & \mathbb{Z}[K(V_1)] \otimes_{R_N} \mathbb{Z}[K(V_2)] \\
\mathbb{Z} \left[ \frac{K(V_1, Y) \oplus K(V_2)}{H^1(N)} \right] & \xrightarrow{P} & \mathbb{Z} \left[ \frac{K(V_1) \oplus K(V_2)}{H^1(N)} \right]
\end{array}$$

Again, since $N$ is admissible

$$\frac{K(V_1) \oplus K(V_2)}{H^1(N)} = \ker(H^2(X) \to H^2(V_1) \oplus H^2(V_2)) = 0.$$

The projection $P$ is induced by some map

$$\frac{K(V_1) \oplus K(V_2)}{H^1(N)} \to \frac{K(V_1, Y) \oplus K(V_2)}{H^1(N)},$$

for which there is only one choice since the domain group is trivial. The construction of $P$ from this map proves the claim. $\square$
Returning with this to Equation (14), we have
\[
\Phi_{X,s}(1) = \Pi_Z (\tau^{-1} \circ F_W \circ F_{Z_1}^{-1} (\Theta) \cdot F_{V_2}^{-1} (\Theta))
\]
\[
= \Pi_Z (F_W^{-1} \circ \tau^{-1} \circ F_{Z_1}^{-1} (\Theta) \cdot F_{V_2}^{-1} (\Theta))
\]
\[
= \Pi_Z (\tau^{-1} \circ F_{Z_1}^{-1} (\Theta) \cdot F_W \circ F_{V_2}^{-1} (\Theta))
\]
(15)

using Lemma 7.9 and Theorem 4.3. Note that the pairings above can be thought of as taking values in
\[
\mathbb{Z} \left[ \frac{K(Z_1) \oplus K(W) \oplus K(V_2)}{H^1(Y) \oplus H^1(N)} \right]
\]
with appropriate grading.

We would like to apply the composition law in (15) to replace \( F_W \circ F_{V_2} \) by \( F_{Z_2}^{-1} \), but we are missing a factor of \( \Pi_{Z_2} \) required by Theorem 2.9. By commutativity of the square \((*)\) in the following diagram, we are free to introduce this factor:

\[
\begin{array}{ccc}
\mathbb{Z}[K(Z_1)] \otimes_{R_Y} \mathbb{Z}[K(Z_2)] & \xrightarrow{1 \otimes \Pi_{Z_2}} & \mathbb{Z}[K(Z_1)] \otimes_{R_Y} \mathbb{Z}[K(Z_2)] \\
\xrightarrow{(*)} & & \\
\mathbb{Z} \left[ \frac{K(Z_1) \oplus K(Z_2)}{H^1(Y)} \right] & \xrightarrow{\Pi_Z} & \mathbb{Z} \left[ \frac{K(Z_1) \oplus K(Z_2)}{H^1(Y)} \right] \\
\xrightarrow{(*)} & & \\
\mathbb{Z} \left[ \frac{K(Z_1) \oplus K(W) \oplus K(V_2)}{H^1(Y) \oplus H^1(N)} \right] & \xrightarrow{\Pi_Z} & \mathbb{Z} \\
\end{array}
\]

Indeed, it follows that \( \Pi_Z = \Pi_Z \circ (1 \otimes \Pi_{Z_2}) \) (after identifying the groups in the column on the left). Thus (15) becomes:

\[
\Phi_{X,s}(1) = \Pi_Z \circ (1 \otimes \Pi_{Z_2}) \cdot (\tau^{-1} \circ F_{Z_1}^{-1} (\Theta) \cdot F_W \circ F_{V_2}^{-1} (\Theta))
\]
\[
= \Pi_Z (\tau^{-1} \circ F_{Z_1}^{-1} (\Theta) \cdot \Pi_{Z_2} \circ F_W \circ F_{V_2}^{-1} (\Theta))
\]
\[
= \Pi_Z (\tau^{-1} \circ F_{Z_1}^{-1} (\Theta) \cdot F_{Z_2}^{-1} (\Theta))
\]

after possibly translating by an element of \( R_Y \). This verifies the “constant coefficient” of (12). For the general statement, suppose \( t = \delta h \in K(X,Y) \). Then since \( s + t = s \) when restricted to \( V_2 \) we can follow the same steps as above (and using the second...
part of Theorem 2.9) to see
\[
\Phi_{X, s+t}^{\ast}(1) = (\tau^{-1} \circ \mathcal{F}_{1, s+t}^{-1}(\Theta^{-}), \mathcal{F}_{V_2, s}^{-1}(\Theta)) \\
= (\tau^{-1} \circ \mathcal{F}_{1, s+t}^{-1}(\Theta^{-}), \mathcal{F}_{V_2, s}^{-1}(\Theta^{-})) \\
= (\tau^{-1} \circ \Pi_{V_1} \circ \mathcal{F}_{W, s}^{-1} \circ e^{-h} \cdot \mathcal{F}_{Z_1, s}^{-1}(\Theta^{-}), \mathcal{F}_{V_2, s}^{-1}(\Theta^{-})) \\
= \Pi_{Z} [e^{-h} \cdot (\tau^{-1} \circ \mathcal{F}_{Z_1, s}^{-1}(\Theta^{-}), \mathcal{F}_{Z_2, s}^{-1}(\Theta^{-}))]
\]
where we can use the same representatives for \([\mathcal{F}_{Z_i, s}^{-1}]\) as before. Since the action of \(R_Y\) on \(\mathbb{Z}[K(X, Y)]\) is via the coboundary, this last expression is exactly the coefficient of \(e^{bh} = e^t\) in \(\langle \tau^{-1} \circ \mathcal{F}_{Z_1, s}^{-1}(\Theta^{-}), \mathcal{F}_{Z_2, s}^{-1}(\Theta^{-}) \rangle\), completing the proof of Theorem 7.6.

8 Perturbed Heegaard Floer invariants

The utility of Theorem 7.6 is limited in many practical circumstances by the restriction on \(b^+(Z_i)\). In particular, if one wishes to split a 4–manifold along the boundary of a tubular neighborhood of a surface of square 0, it is not obvious whether the assumptions of that theorem are satisfied. In this section we show how to remedy this circumstance by making use of Heegaard Floer homology “perturbed” by a 2–dimensional cohomology class \(\eta \in H^2(Y; \mathbb{R})\). (A version of this theory was mentioned briefly in [12]; here we give a rather fuller treatment.)

8.1 Definitions and basic properties

**Definition 8.1** Fix a closed oriented 3–manifold \(Y\) and a class \(\eta \in H^2(Y; \mathbb{R})\). The Novikov ring associated to \((Y, \eta)\) is the ring \(\mathcal{R}_{Y, \eta} \subset \mathbb{Z}H^1(Y; \mathbb{Z})\) of \(\mathbb{Z}\)–valued functions on \(H^1(Y; \mathbb{Z})\) defined by the condition that \(f \in \mathcal{R}_{Y, \eta}\) if and only if for each \(N \in \mathbb{Z}\), the set \(\text{supp}(f) \cap \{a \in H^1(Y)| \langle a \cup \eta, [Y] \rangle < N\}\) is finite.

More concretely, we can think of \(\mathcal{R}_{Y, \eta}\) as the collection of formal series

\[
\mathcal{R}_{Y, \eta} = \left\{ \sum_{g \in H^1(Y; \mathbb{Z})} a_g \cdot g \mid a_g \in \mathbb{Z} \right\}
\]

subject to the condition that for each \(N \in \mathbb{Z}\) the set of \(g \in H^1(Y)\) with \(a_g\) nonzero and \(\langle g \cup \eta, [Y] \rangle < N\) is finite.

The multiplication on \(\mathcal{R}_{Y, \eta}\) is the usual convolution product; note that in the case \(\eta = 0\) we have \(\mathcal{R}_{Y, 0} = \mathbb{Z}[H^1(Y)]\). Clearly, \(\mathcal{R}_{Y, \eta} = \mathcal{R}_{Y, c\eta}\) for any positive constant \(c\). Furthermore, \(\mathcal{R}_{Y, \eta}\) depends on the orientation of \(Y\) in the sense that \(\mathcal{R}_{Y, \eta} = \mathcal{R}_{Y, -\eta}\).
The above is an instance of a general construction: given an abelian group $G$ and a homomorphism $\eta : G \to \mathbb{R}$, we can form an associated Novikov ring $\mathcal{N}(G, \eta)$ as a subset of $\mathbb{Z}^G$. Namely,

$$\mathcal{N}(G, \eta) = \left\{ \sum_{g \in G} a_g \cdot g \mid a_g \in \mathbb{Z} \right\},$$

with the condition that for each $N \in \mathbb{Z}$ the set of $g \in G$ with $a_g$ nonzero and $\eta(g) < N$ is finite. We now pause to remark on the functoriality of this construction.

Suppose $(G, \eta)$ and $(H, \nu)$ are two groups with homomorphisms to $\mathbb{R}$, and $f: G \to H$ is a group homomorphism. There are two ways in which one might wish to associate a homomorphism between $\mathcal{N}(G, \eta)$ and $\mathcal{N}(H, \nu)$. First is a “pushforward”

$$\hat{f}_* : \mathcal{N}(G, \eta) \to \mathcal{N}(H, \nu)$$

defined by

$$\hat{f}_* \left( \sum_{g \in G} a_g \cdot g \right) = \sum_{g \in G} a_g \cdot f(g) = \sum_{h \in H} b_h \cdot h,$$

where $b_h$ is the sum of all $a_g$ for $g \in f^{-1}(h)$. For the above to make sense we must have that each collection \{ $g \in f^{-1}(h) \mid a_g \neq 0$ \} is finite, and for the above to define an element of $\mathcal{N}(H, \nu)$ we need the set \{ $h \mid h \in \text{im}(f), \nu(h) < N$ \} to be finite for each $N$. It is easy to see that both of these properties are satisfied if whenever $S \subset H$ is a subset on which $\nu$ is bounded, the function $\eta$ is bounded on $f^{-1}(S)$, which in turn is true if $\eta = \nu \circ f$. In this situation, the expression above gives a well-defined function $\hat{f}_*$, which is easily seen to be a ring homomorphism.

On the other hand we can define a “pullback” map

$$\hat{f}^* : \mathcal{N}(H, \nu) \to \mathcal{N}(G, \eta)$$

defined by

$$\hat{f}^* \left( \sum_{h \in H} b_h \cdot h \right) = \sum_{g \in G} b_{f(g)} \cdot g.$$

The expression above defines an element of $\mathcal{N}(G, \eta)$ if the set \{ $g \mid b_{f(g)} \neq 0$ and $\eta(g) < N$ \} is finite for each $N$. This will happen if whenever $\eta$ is bounded on a subset $S \subset G$ we have that $\nu$ is bounded on $f(S)$, and additionally, $\ker(f)$ is finite. In particular, if $\eta = \nu \circ f$ and $f$ is injective, $\hat{f}^*$ is a well-defined function. In general, $\hat{f}^*$ is not a ring homomorphism. However, we can regard $\mathcal{N}(H, \nu)$ as a module over $\mathcal{N}(G, \eta)$ using the homomorphism $\hat{f}_*$ constructed above, and then one can check that $\hat{f}^*$ is a homomorphism of $\mathcal{N}(G, \eta)$–modules.
To summarize:

**Lemma 8.2** Suppose \( G \) and \( H \) are abelian groups and \( \eta \colon G \to \mathbb{R} \) and \( \nu \colon H \to \mathbb{R} \) are additive homomorphisms. Let \( f \colon G \to H \) be a homomorphism with the property that \( \eta = \nu \circ f \). Then there is a well-defined homomorphism

\[
\widehat{f}_*: N(G, \eta) \to N(H, \nu)
\]

of Novikov rings.

If in addition \( f \) is injective, then there is a well-defined pullback or “restriction” map

\[
\hat{f}^*: N(H, \nu) \to N(G, \eta),
\]

which is a homomorphism of \( N(G, \eta) \)–modules.

It is easy to see that the above constructions are functorial with respect to compositions of homomorphisms. Furthermore, if \( f \) is injective then clearly \( \hat{f}^* \circ \hat{f}_* = \text{id}_{N(G, \eta)} \), so in this case \( \hat{f}^* \) is surjective and \( \hat{f}_* \) is injective.

We can now recite the definition of twisted-coefficient Heegaard Floer homology using the Novikov ring \( R_{Y, \eta} \) in place of \( R_Y \).

**Definition 8.3** Let \((Y, s)\) be a closed oriented spinc 3–manifold, and let \( \eta \in H^2(Y; \mathbb{R}) \). Endow \( R_{Y, \eta} \) with the \( s \)–grading defined by (5). Let \((\Sigma, \alpha, \beta, z)\) be a marked Heegaard diagram for \( Y \), and choose an additive assignment \( A \) for the diagram. The \( \eta \)–perturbed Heegaard Floer complex is the free \( R_{Y, \eta} \)–module \( CF^\infty(Y, s; R_{Y, \eta}) \) generated by pairs \([x, i]\) where \( x \in T_\alpha \cap T_\beta \) is an intersection point with \( s_z(x) = s \), equipped with the relative \( \mathbb{Z} \) grading defined in (6).

The boundary operator is given as in Definition 2.3, where \( e^{A(\phi)} \) is interpreted as an element of \( R_{Y, \eta} \).

If \((\Sigma, \alpha, \beta, z)\) is strongly \( s \)–admissible, in the sense of [12, Definition 4.10], then the definition above obviously yields the Heegaard Floer complex for the unperturbed theory with coefficients in the \( R_Y \)–module \( R_{Y, \eta} \); ie, the complex \( CF^\phi(Y, s; R_Y) \otimes_{R_Y} R_{Y, \eta} \).

In fact, the perturbed complex can be defined with relaxed admissibility hypotheses: if \( \eta \) is generic in the sense that the induced map \( H^1(Y; \mathbb{Z}) \to \mathbb{R} \) is injective, weak admissibility suffices to define \( H\!F^\infty(Y, s; R_{Y, \eta}) \) and \( H\!F^-(Y, s; R_{Y, \eta}) \), while no admissibility conditions are necessary to define \( H\!F^+(Y, s; R_{Y, \eta}) \) or \( \hat{H}\!F(Y, s; R_{Y, \eta}) \). However, we have no need for this generality, and the observation in the previous paragraph suffices to show that the perturbed Heegaard Floer homology is a topological invariant of \((Y, s, \eta)\).

*Geometry & Topology, Volume 12 (2008)*
Note that if $M$ is a (graded) module for $R_Y$, we can obtain a module for $\mathcal{R}_{Y,\eta}$ by tensor product: $\mathcal{M}_\eta = M \otimes_{R_Y} \mathcal{R}_{Y,\eta}$. Thus we can consider perturbed Heegaard Floer homology with coefficients in the “completed” module $\mathcal{M}_\eta$, namely the homology of the complex $CF(Y; s; \mathcal{R}_{Y,\eta}) \otimes_{\mathcal{R}_{Y,\eta}} \mathcal{M}_\eta$ (of course, since any module for $\mathcal{R}_{Y,\eta}$ is also a module for $R_Y$, we see trivially that any $\mathcal{R}_{Y,\eta}$ module is obtained in this way).

Calculation of perturbed Floer homology is facilitated by the following.

**Lemma 8.4** For any $\eta \in H^2(Y; \mathbb{R})$, the ring $\mathcal{R}_{Y,\eta}$ is flat as an $R_Y$–module.

**Proof** Let $K$ denote the kernel of the homomorphism $H^1(Y; \mathbb{Z}) \to \mathbb{R}$ given by $x \mapsto \langle x \cup \eta, [Y] \rangle$; note that $K$ is a direct summand of $H^1(Y; \mathbb{Z})$. Let $rk(K) = k$. The ring $R_Y$ can be identified with a Laurent polynomial ring in variables $\{x_1, \ldots, x_b\}$, $b = b_1(Y)$, and we can choose the generators $x_i$ such that $\langle x_i \cup \eta, [Y] \rangle = 0$ for $i = 1, \ldots, k$, while $\langle x_i \cup \eta, [Y] \rangle > 0$ for $i > k$. The Novikov ring $\mathcal{R}_{Y,\eta}$ can be constructed as follows. First let $\mathbb{Z}_\eta$ denote the (“partial”) power series ring obtained by completing the ring $\mathbb{Z} = \mathbb{Z}[x_1, \ldots, x_b]$ with respect to the ideal generated by $x_{k+1}, \ldots, x_b$. Then if $V$ denotes the multiplicative subset generated by the variables $x_1, \ldots, x_b$, we have that $\mathcal{R}_{Y,\eta} = V^{-1} \mathbb{Z}_\eta$. It is a standard fact that $\mathbb{Z}_\eta$ is flat over $\mathbb{Z}$ (see, eg, [1, Theorem 7.2]), and it follows easily that $\mathcal{R}_{Y,\eta} = V^{-1} \mathbb{Z}_\eta$ is flat over $R_Y = V^{-1} \mathbb{Z}$. □

**Definition 8.5** Let $Y$ be a closed oriented 3–manifold, $s \in \text{Spin}^c(Y)$, and $\eta \in H^2(Y; \mathbb{R})$. We say $\eta$ is *generic for $s$* if $\ker(c_1(s)) \not\subset \ker(\eta)$. That is to say, $\eta$ is generic for $s$ if there exists a class $x \in H^1(Y)$ such that

$$\eta \cup x \neq 0 \quad \text{but} \quad c_1(s) \cup x = 0.$$  

Observe that if $c_1(s)$ is torsion and $\eta$ is nonzero then $\eta$ is automatically generic for $s$, while if $b_1(Y) = 1$ and $c_1(s)$ is nontorsion, then a generic class $\eta$ for $s$ does not exist. Once $b_1(Y) > 1$, however, any class $\eta \in H^2(Y; \mathbb{R})$ that is “generic” in the sense that $\langle \eta \cup \cdot, [Y] \rangle$ is injective is automatically generic for any spin$^c$ structure $s$.

In Seiberg–Witten theory, once $b_1(Y) > 0$ it is possible to “perturb away” reducible solutions to the Seiberg–Witten equations on $Y$. The following can be seen as an analog of that statement in Heegaard Floer theory.

**Corollary 8.6** If $\eta \in H^2(Y; \mathbb{R})$ is generic for a spin$^c$ structure $s$ on $Y$, then $HF^\infty(Y; s; \mathcal{R}_{Y,\eta}) = 0$.  

*Geometry & Topology, Volume 12 (2008)*
and therefore $HF^\infty(Y, s; \mathcal{M}) = 0$ for any $\mathcal{R}_{Y, \eta}$–module $\mathcal{M}$. In particular, under this assumption, for any $R_Y$–module $M$ with completion $\mathcal{M}_\eta = M \otimes_{R_Y} \mathcal{R}_{Y, \eta}$ we have isomorphisms

$$HF^\pm(Y, s; \mathcal{M}_\eta) = HF^\pm_{\text{red}}(Y, s; \mathcal{M}_\eta) \cong HF^\pm_{\text{red}}(Y, s; M) \otimes_{R_Y} \mathcal{R}_{Y, \eta}.$$  

**Proof** By the previous lemma, $HF^\infty(Y, s; \mathcal{R}_{Y, \eta}) \cong HF^\infty(Y, s; R_Y) \otimes_{R_Y} \mathcal{R}_{Y, \eta}$. Oszváth and Szabó showed [11, Theorem 10.12, Remark 10.13] that for any 3–manifold $Y$, the fully-twisted Floer homology satisfies

$$HF^\infty(Y, s; R_Y) \cong \mathbb{Z}[U, U^{-1}]$$

where an element $x \in H^1(Y; \mathbb{Z})$ having $\langle c_1(s) \cup x, [Y] \rangle = 2k$ acts as multiplication by $U^k$. Take $x$ to be as in the definition of generic above, so that $k = 0$. Without loss of generality we can assume that $\langle \eta \cup x, [Y] \rangle > 0$, so that the element $1 - x$ has an inverse $\sum_{n \geq 0} x^n$ in $\mathcal{R}_{Y, \eta}$. But then $1 - x$ is a unit that acts as 0 on $HF^\infty(Y, s; \mathcal{R}_{Y, \eta})$, meaning the latter module must vanish. The remaining statements follow easily from the flatness of $\mathcal{R}_{Y, \eta}$.

As noted above, it is not always possible to guarantee the existence of a generic perturbation (namely when $b_1(Y) \leq 1$). Of more concern for our purposes, a similar situation arises when considering cobordisms $W: Y_1 \to Y_2$, where perturbations and spin$^c$ structures on $Y_i$ are taken to be induced from $W$. Here if $b_2(W) = 1$, for example, then any class $\eta$ induced from $W$ must be a multiple of the Chern class of a spin$^c$ structure on $Y_2$ induced from $W$, and again we cannot arrange genericity regardless of the value of $b_1(Y)$.

To deal with this situation we make a further completion of Heegaard Floer homology, this time with respect to $U$.

**Definition 8.7** Let $\mathbb{Z}[\llbracket U \rrbracket]$ denote the ring of integer power series in $U$. The $U$–completed Heegaard Floer groups for $(Y, s, \eta)$ in a module $\mathcal{M}$ are defined by

$$HF^\bullet_{\underline{U}}(Y, s; \mathcal{M}) = HF^\bullet(Y, s; \mathcal{M}) \otimes_{\mathbb{Z}[U]} \mathbb{Z}[\llbracket U \rrbracket].$$

Thus the perturbed, completed Floer homology $HF^\bullet_{\underline{U}}(Y, s; \mathcal{M})$ is a module for $\mathcal{R}_{Y, s}[\llbracket U \rrbracket]$. Observe that since the action of $U$ is nilpotent on elements of $HF^+$, this completion has no effect on the latter group:

$$HF^\bullet_{\underline{U}}(Y, s; \mathcal{M}) = HF^+(Y, s; \mathcal{M}).$$

There is a natural map $\text{HF}^\circ(Y, s; \mathcal{M}) \to \text{HF}_Y^\circ(Y, s; \mathcal{M})$ that is typically (when $\eta$ is generic for $s$, for example) an injection. We will often implicitly make use of this homomorphism when extending previous results to the $U$–completed setting.

The definition is most useful when the uncompleted group $\text{HF}^\circ(Y, s; \mathcal{M})$ carries a relative $\mathbb{Z}$–grading (not a cyclic grading). We will generally be interested in coefficient modules $\mathcal{M}$ that arise from cobordisms $S^3 \to Y$, and in light of Proposition 3.5 we will therefore be in the $\mathbb{Z}$–graded case.

**Corollary 8.8** Let $(Y, s)$ be a closed spin$^c$ 3–manifold and $\eta \in H^2(Y; \mathbb{R})$ a fixed class. If $c_1(s)$ is torsion, assume that $\eta \neq 0$. Then

$$\text{HF}_Y^\circ(Y, s; \mathcal{M}_\eta) = 0$$

for any $\mathcal{R}_{Y, \eta}$ module $\mathcal{M}_\eta$.

The other conclusions of Corollary 8.6 of course follow as well for the $U$–completed Floer homology perturbed by a compatible class $\eta$. Note that if $c_1(s)$ is nontorsion, then it suffices to take $\eta = 0$.

**Proof** It suffices to show the vanishing with coefficients in $\mathcal{R}_{Y, \eta}$; if $c_1(s)$ is torsion then a nonzero $\eta$ is necessarily generic for $s$ so that Corollary 8.6 applies. Otherwise, we can find $t \in H^1(Y)$ such that $\langle c_1(s) \cup t, [Y] \rangle = -2k$ with $k > 0$; then as before $t$ acts as multiplication by $U^{-k}$ on $\text{HF}_Y^\circ(Y, s; \mathcal{R}_Y)$. Hence the element $1 - tU^k$ acts as 0, but the former is a unit in the completed ring $\mathcal{R}_{Y, \eta}[[U]]$. □

We now wish to extend perturbed Heegaard Floer theory to cobordism-induced homomorphisms. To do so, we again follow the program from the unperturbed case; we need only make sure that the coefficient modules respect the algebraic nature of the Novikov rings.

**Definition 8.9** Let $W: Y_1 \to Y_2$ be an oriented cobordism between 3–manifolds $Y_1$, and fix $\eta \in H^2(W; \mathbb{R})$ with restrictions $\eta_i = \eta|_{Y_i}$. Let $\mathcal{K}(W, \eta)$ be the Novikov completion of $\mathbb{Z}[K(W)]$ with respect to $\eta$, where as usual $K(W) = \text{im} \left( H^1(\partial W; \mathbb{Z}) \to H^2(W, \partial W; \mathbb{Z}) \right)$. Concretely, $\mathcal{K}(W, \eta)$ is the ring of formal series

$$\mathcal{K}(W, \eta) = \left\{ \sum_{g \in K(W)} a_g \cdot g \mid a_g \in \mathbb{Z} \right\}$$

subject to the condition that for each $N \in \mathbb{Z}$ the set of $g \in K(W)$ with $a_g$ nonzero and $\langle g \cup \eta, [W, \partial W] \rangle < N$ is finite. Then $\mathcal{K}(W, \eta)$ is a module for both $\mathcal{R}_{Y_1, \eta_1}$ and $\mathcal{R}_{Y_2, \eta_2}$.
If $\mathcal{M}$ is a (graded) module for $\mathcal{R}_{Y_1,\eta_1}$, the module $\mathcal{M}(W, \eta)$ for $\mathcal{R}_{Y_2,\eta_2}$ induced by $(W, \eta)$ is defined by

$$\mathcal{M}(W, \eta) = \overline{\mathcal{M}} \otimes_{\mathcal{R}_{-Y_1,\eta_1}} \mathcal{K}(W, \eta).$$

The module structure of $\mathcal{K}(W, \eta)$ over $\mathcal{R}_{-Y_1,\eta_1}$ and $\mathcal{R}_{Y_2,\eta_2}$ is induced by the maps $\delta: H^1(Y_1) \to H^2(W, \partial W)$, as usual. The fact that these maps induce well-defined homomorphisms between Novikov rings relies on Lemma 8.2, together with the fact that $\eta_i$ is the restriction of $\eta$. Note that $\mathcal{K}(W, \eta)$ can be given an integer grading depending on a choice of spin$^c$ structure just as in Proposition 3.5.

For the conjugate module appearing in the last statement of the definition, observe that the map $x \mapsto -x$ in $H^1(Y)$ induces a conjugation map $\mathcal{R}_{Y,\eta} \to \mathcal{R}_{-Y,\eta}$. Thus $\mathcal{M}$, defined to be the same graded group as $\mathcal{M}$ with conjugate module structure, makes sense as a graded $\mathcal{R}_{-Y,\eta}$–module.

It is now straightforward to define a homomorphism

$$F^\omega_{W,\eta,s}: HF^\omega_\bullet(Y_1, s_1, \mathcal{M}) \to HF^\omega_\bullet(Y_2, s_2, \mathcal{M}(W, \eta))$$

associated to a spin$^c$ cobordism $(W, s)$ with chosen perturbation $\eta$ (or similar maps between the groups without the “$\cdot$”), by making the usual formal construction for 1– and 3–handles, and using Definition 2.6 for the 2–handles, where $e^{A_W}\psi$ is considered to lie in $\mathcal{K}(W, \eta)$. The proof that the result of this construction is a chain map whose induced map in homology is an invariant of $W$ (up to a sign and the action of $H^1(Y_1; \mathbb{Z}) \oplus H^1(Y_2; \mathbb{Z})$) is identical to the proof in the unperturbed case in [15]. Alternatively, one can deduce this fact from the corresponding fact in the unperturbed theory using Lemma 8.4.

Similarly, there is a composition law for perturbed cobordism maps that follows from the usual one given in Theorem 2.9. Indeed, suppose we are given a cobordism $W: Y_1 \to Y_2$ and a module $M$ for $\mathcal{R}_Y$, along with a class $\eta \in H^2(W; \mathbb{R})$. Write $\mathcal{M} = M \otimes_{\mathcal{R}_{Y_1}} \mathcal{R}_{Y_1,\eta}$ for the Novikov completion of $M$ (we do not distinguish in the notation between $\eta$ and its restrictions to $Y_1$, $Y_2$); then $\mathcal{M}$ can also be considered as an $\mathcal{R}_{Y_1}$–module. As such, we obtain an induced $\mathcal{R}_{Y_2}$–module $\mathcal{M}(W) = \overline{\mathcal{M}} \otimes_{\mathcal{R}_{-Y_1}} \mathbb{Z}[K(W)]$.

It is not hard to see that the $\mathcal{R}_{Y_2,\eta}$–module induced by $(W, \eta)$ is then

$$\mathcal{M}(W, \eta) = \mathcal{M}(W) \otimes_{\mathcal{R}_{Y_2}} \mathcal{R}_{Y_2,\eta} = \mathcal{R}_{-Y_1,\eta} \otimes_{\mathcal{R}_{-Y_1}} \mathcal{M}(W) \otimes_{\mathcal{R}_{Y_2}} \mathcal{R}_{Y_2,\eta}$$
and we have a commutative diagram (with or without \( \bullet \)'s)

\[
\begin{array}{ccc}
HF_\bullet(Y_1, \mathcal{M}) & \xrightarrow{F_W} & HF_\bullet(Y_2, \mathcal{M}(W)) \\
& \overset{1}{\otimes} & HF_\bullet(Y_2, \mathcal{M}(W)) \otimes_{R_{Y_2}} R_{Y_2, \eta} \\
& F_W, \eta & \\
& & HF_\bullet(Y_2, \mathcal{M}(W, \eta))
\end{array}
\]

where the vertical arrow is an isomorphism according to Lemma 8.4. Combining this observation with the original composition law gives the desired result for perturbed Floer homology.

All of the algebraic constructions earlier introduced for twisted coefficients go through with only minor modifications in the perturbed setup. The action of \( H_1(Y; \mathbb{Z})/\text{tors} \) on \( HF_*^\mathfrak{s}(Y, s; \mathcal{M}) \) for \( \mathcal{M} \) an \( R_{Y, \eta} \)-module is defined just as before, as is the extension of cobordism-induced maps to incorporate this action. Likewise the previous definition applies to give a pairing

\[
HF_*^+ (Y, s; \mathcal{M}) \otimes_{R_{Y, \eta}} HF_*^- (-Y, s; \bar{\mathcal{N}}) \to \mathcal{M} \otimes_{R_{Y, \eta}} \bar{\mathcal{N}}
\]

for any \( R_{Y, \eta} \)-module \( \mathcal{M} \) and \( R_{-Y, \eta} \)-module \( \bar{\mathcal{N}} \) (and similarly without \( \bullet \)'s).

### 8.2 Conjugation and orientation reversal

The perturbed versions of the results of Section 6 are straightforward generalizations, with the caveat that conjugation \( R_{Y, s} \to R_{Y, \bar{s}} \) extends to the setting of Novikov rings only at the cost of reversing the sign of \( \eta \). Indeed, if \( r \in R_{Y, s, \eta} \), we can consider the conjugate \( \bar{r} \) to lie either in \( R_{-Y, s, \eta} \) or in \( R_{Y, \bar{s}, -\eta} \). Hence if \( \mathcal{M} \) is a module for \( R_{Y, s, \eta} \), we can think of \( \bar{\mathcal{M}} \) as a module either for \( R_{-Y, s, \eta} \) or for \( R_{Y, \bar{s}, -\eta} \).

**Theorem 8.10** If \((Y, s)\) is a closed spin\(^c\) 3–manifold with class \( \eta \in H^2(Y; \mathbb{R}) \), and \( \mathcal{M} \) is a module for \( R_{Y, \eta} \), then we have an isomorphism of \( R_{Y, \eta} \)-modules

\[
HF_*^\theta (Y, s; \mathcal{M}) \cong HF_*^\theta (Y, \bar{s}; \bar{\mathcal{M}})
\]

preserving relative gradings, where \( \bar{\mathcal{M}} \) is considered as a module for \( R_{Y, \bar{s}, -\eta} \). In particular,

\[
HF_*^\theta (Y, s; R_{Y, s, \eta}) \cong HF_*^\theta (Y, \bar{s}, R_{Y, s, \eta}) \cong HF_*^\theta (Y, \bar{s}, R_{Y, \bar{s}, -\eta}).
\]

Thus in the perturbed case, there is a natural equivalence between Floer homology for spin\(^c\) structure \( s \) perturbed by a form \( \eta \), and the homology for \( \bar{s} \) perturbed by \( -\eta \).
Theorem 8.11  For \((Y, s)\) a closed oriented spin\(^c\) 3–manifold with class \(\eta \in H^2(Y; \mathbb{R})\), and \(\mathcal{M}\) a module for \(\mathcal{R}_{Y, \eta}\), there is an isomorphism
\[
HF^\pm(Y, s; \mathcal{M}) \cong HF^\pm(-Y, s; \mathcal{N}),
\]
of relatively graded \(\mathcal{R}_{Y, s, \eta}\–modules, where \(\mathcal{N}\) is a module for \(\mathcal{R}_{-Y, s, \eta}\).

As usual, there are obvious analogues of each of these results before taking \(U\)–completions.

### 8.3 Perturbed 4–manifold invariants

We are now in a position to define invariants for closed 4–manifolds using perturbed Floer homology. If \((Z, s)\) is a spin\(^c\) 4–manifold with boundary \(Y\) and \(\eta \in H^2(Z; \mathbb{R})\), we define the perturbed relative invariant for \((Z, s)\) to be the map
\[
\Psi_{Z, s, \eta}: \mathbb{A}(Z) \to HF^\pm(Y, s; K(Z, \eta))
\]
given by \(\Psi_{Z, s, \eta}(U^n \otimes \omega) = [F^\pm_{Z, s, \eta}(U^n \cdot \Theta^- \otimes \omega)]\), where the brackets indicate the equivalence class under the action of \(K(Z)\) as before. Here \(K(Z, \eta)\) is the \(\mathcal{R}_{Y, \eta}\–module induced by \(Z\), thought of as a cobordism \(S^3 \to Y\); in other words \(K(Z, \eta)\) is the Novikov completion of \(\mathbb{Z}[\ker(H^2(Z, Y) \to H^2(Z))]\) with respect to \(\eta\).

Definition 8.12  Let \(X\) be a closed 4–manifold and \(\eta \in H^2(X; \mathbb{R})\). An oriented 3–dimensional embedded submanifold \(Y \subset X\) is an allowable cut for \(X\) if \(Y\) separates \(X\) into two components, \(X = Z_1 \cup Y \backslash Z_2\) with \(\partial Z_1 = Y = -\partial Z_2\), and at least one of the following conditions are satisfied:

1. \(\eta|_Y \neq 0\).
2. \(b^+(Z_i) \geq 1\) for \(i = 1, 2\).

Observe that if property (1) of the definition holds, then it follows from Corollary 8.6 that the induced map \(F^\infty_{Z, s, \eta}\) is trivial in perturbed, \(U\)–completed Floer homology for any spin\(^c\) structure on \(X\). (Indeed, if the restriction of \(c_1(s)\) to \(Y\) is a nontorsion class then we need not even assume (1), but of course in this case one can always find a class \(\eta\) satisfying (1), namely the image in real cohomology of \(c_1(s)\). To avoid complicating the statements of results to follow, we ignore this point.)

On the other hand, if \(W: Y_1 \to Y_2\) is a cobordism with \(b^+(W) > 0\) and \(\eta \in H^2(W; \mathbb{R})\), then since the unperturbed map in \(HF^\infty\) induced by \(W\) is trivial, the same is true for the map perturbed by \(\eta\), whether \(\eta\) vanishes on \(\partial W\) or not. Hence the perturbed relative invariant \(\Psi_{Z, s, \eta}\) for a component of \(X\) arising from a cut allowable for \(\eta\), takes values in the reduced Floer homology in both cases, and the following makes sense.
Definition 8.13  Let $X$ be a closed oriented 4–manifold and $s$ a spin\,\!^c structure on $X$. For a pair $(Y, \eta)$ consisting of an element $\eta \in H^2(X; \mathbb{R})$ and a cut $X = Z_1 \cup_Y Z_2$ of $X$ that is allowable for $\eta$, the perturbed Ozsváth–Szabó invariant of $X$ associated to $(Y, \eta, s)$ is the linear map $\Phi_{X,Y,\eta,s} : \mathcal{A}(X) \to \mathcal{K}(X,Y,\eta)$ defined by
\[
\Phi_{X,Y,\eta,s}(\alpha) = (\tau^{-1} \Psi_{Z_1,s,\eta}(\alpha_1), \Psi_{Z_2,s,\eta}(\alpha_2)),
\]
up to sign and multiplication by an element of $K(X,Y)$. Here $\alpha$ is the image of $\alpha_1 \otimes \alpha_2$ under the natural map $\mathcal{A}(Z_1) \otimes \mathcal{A}(Z_2) \to \mathcal{A}(X)$.

In this definition, we set
\[
\mathcal{K}(X,Y,\eta) = \mathcal{K}(Z_1,\eta) \otimes_{R_{Y,\eta}} \mathcal{K}(Z_2,\eta).
\]
This can be identified with the Novikov completion of the $R_Y$–module $\mathbb{Z}[K(X,Y)]$ with respect to $\eta$ as in Lemma 2.7. That is to say, $\mathcal{K}(X,Y,\eta) = \mathbb{Z}[K(X,Y)] \otimes_{R_Y} R_{Y,\eta}$. Note that $\Phi_{X,Y,\eta,s}$ depends on the orientation of $Y$ in the sense that $\Phi_{X,Y,\eta,s} = \Phi_{X,-Y,\eta,s}$. Indeed, it is easy to see that the two are related by the action of the obvious antihomomorphism $\mathcal{K}(Z_1,\eta) \otimes \mathcal{K}(Z_2,\eta) \to \mathcal{K}(Z_2,\eta) \otimes \mathcal{K}(Z_1,\eta)$, which in turn corresponds to the conjugation homomorphism $\mathcal{K}(X,Y,\eta) \to \mathcal{K}(X,-Y,\eta)$.

We will see that when $b^+(X) \geq 2$, the definition above recovers the ordinary Ozsváth–Szabó invariants in the sense of Theorem 7.6: that is, $\Phi_{X,Y,\eta,s}$ lies in $\mathbb{Z}[K(X,Y)]$, and the coefficients of this group ring element are the Ozsváth–Szabó invariants of $X$ in the various spin\,\!^c structures that have given restrictions to $Z_1$ and $Z_2$. The utility of this definition is that we no longer need to assume that $b^+(Z_i) \geq 1$ or even that $F_{Z_i,s}^-$ takes values in the reduced Floer homology, so long as $\eta|_Y \neq 0$.

It should be noted, however, that the existence of a 3–manifold $Y$ separating $X$ and a class $\eta \in H^2(X; \mathbb{R})$ restricting nontrivially to $Y$ implies that $X$ is indefinite; in particular $b^+(X) \geq 1$.

Lemma 8.14  Suppose $X$ is a 4–manifold with $b^+(X) \geq 2$, $Y$ a submanifold splitting $X$ into components $Z_1$ and $Z_2$ with $b^+(Z_i) \geq 1$ (or more generally satisfying the hypotheses of Theorem 7.6), and $\eta \in H^2(X; \mathbb{R})$ a perturbing class on $X$. Then for any spin\,\!^c structure $s$ on $X$, $\Phi_{X,Y,\eta,s}$ takes values in $\mathbb{Z}[K(X,Y)] \subset \mathcal{K}(X,Y,\eta)$, and
\[
\Phi_{X,Y,\eta,s} = \sum_{t \in K(X,Y)} \Phi_{X,s+t} \cdot e^t
\]
up to multiplication by $\pm 1$ and an element of $K(X,Y)$.
Proof We have a commutative diagram

\[
\begin{array}{c}
HF^- (S^3) \rightarrow HF^- (Y, \mathbb{Z}[K(Z_1)]) \\
\downarrow i_* \quad \downarrow i_* \\
HF^- (S^3) \rightarrow HF^- (Y, \mathbb{Z}[K(Z_1, \eta)])
\end{array}
\]

(18)

where the upper arrow is the unperturbed, twisted-coefficient homomorphism induced by \((Z_1, s)\), and the lower arrow uses the perturbation \(\eta|_{Z_1}\). Here \(i_*\) is the natural map induced by the homomorphism \(\mathbb{Z}[K(Z_1)] \rightarrow \mathbb{K}(Z_1, \eta)\) of a ring to its Novikov completion; commutativity of the diagram is obvious from the definition of cobordism-induced maps. We have a similar diagram for \(Z_2\) with \(Y\) replaced by \(-Y\).

Likewise, there is a diagram:

\[
\begin{array}{c}
HF^- \left( Y, \mathbb{Z}[K(Z_1)] \right) \otimes_{\mathbb{R} Y} HF^- \left( -Y, \mathbb{Z}[K(Z_2)] \right) \xrightarrow{\left( \tau^{-1}(1), \cdot \right)} \mathbb{Z}[K(X, Y)] \\
i_* \otimes i_* \quad \downarrow j \\
HF^\bullet \left( Y, \mathbb{K}(Z_1, \eta) \right) \otimes_{\mathbb{R} Y, \eta} HF^\bullet \left( -Y, \mathbb{K}(Z_2, \eta) \right) \xrightarrow{\left( \tau^{-1}(1), \cdot \right)} \mathbb{K}(X, Y, \eta)
\end{array}
\]

(19)

If \(\eta|_Y = 0\), then the maps \(i_*\) and \(j\) are the identity maps: indeed, it follows from (16) that \(\mathbb{K}(Z_1, \eta) = \mathbb{Z}[K(Z_1)]\) and \(\mathbb{K}(X, Y, \eta) = \mathbb{Z}[K(X, Y)]\). Thus in this case, the lemma is just a restatement of Theorem 7.6.

Assume that \(\eta|_Y \neq 0\). We claim that the map \(j: \mathbb{Z}[K(X, Y)] \rightarrow \mathbb{Z}[K(X, Y)] \otimes_{\mathbb{R} Y} \mathbb{R} Y, \eta\) is injective, and this combined with Theorem 7.6 clearly implies the lemma. To see the injectivity, observe that since \(\eta\) is induced from the 4–manifold \(X\), we have a diagram

\[
\begin{array}{c}
H^1(Y; \mathbb{Z}) \xrightarrow{\delta} K(X, Y) \\
\downarrow \sigma_{\eta, [Y]} \\
\mathbb{R} \xrightarrow{\eta \cup \cdot [X]}
\end{array}
\]

with \(\delta\) surjective (recall that \(K(X, Y)\) is identified with a subgroup of \(H^2(X); cf \) Remark 2.8). From this it follows that the Novikov completion of \(\mathbb{Z}[K(X, Y)]\) as an \(\mathbb{R} Y\)–module is the same as its Novikov completion \(\mathcal{N}(K(X, Y), \eta)\) as a ring with respect to the function \(\eta \cup \cdot [X]\). It is straightforward to see that the map \(\mathbb{Z}[G] \rightarrow \mathcal{N}(G, \eta)\) from a group ring to its Novikov completion is injective. \(\square\)
Remark 8.15 The injectivity of \( j : \mathbb{Z}[K(X, Y)] \to \mathbb{Z}[K(X, Y)] \otimes_{\mathbb{R}_Y} \mathcal{R}_{Y, \eta} \) from \( \mathbb{Z}[K(X, Y)] \) to its (module) completion is not automatic, as can be seen in the case of a cut \( Y \) that is admissible in the sense of Ozsváth and Szabó: in this case \( K(X, Y) \) is trivial, \( \mathbb{Z}[K(X, Y)] \cong \mathbb{Z} \), and \( \mathbb{Z} \otimes_{\mathbb{R}_Y} \mathcal{R}_{Y, \eta} = 0 \) if \( \eta \neq 0 \).

To handle cases where not both sides of the cut \( Y \) have nonvanishing \( b^+ \), we consider the dependence of \( \Phi_{X, Y, \eta, s} \) on \( Y \). For our present purposes, it suffices to assume that we are given a closed 4–manifold \( X \) with two disjoint cuts \( Y_1 \) and \( Y_2 \), and both cuts are allowable for a class \( \eta \in H^2(X; \mathbb{R}) \). Assume also that the orientations on \( Y_1 \) and \( Y_2 \) are compatible, in the sense that in the decomposition \( X = Z_1 \cup Y_1, Z_2 \cup Y_2, Z_3 \), we have \( \partial Z_1 = Y_1, \partial Z_2 = -Y_1 \cup Y_2 \), and \( \partial Z_3 = -Y_2 \). We consider the Ozsváth–Szabó invariants \( \Phi_{X, Y_1, \eta, s} \) and \( \Phi_{X, Y_2, \eta, s} \), and for simplicity we calculate in particular their values on \( \alpha = 1 \in \mathbb{A}(X) \) (which we omit from the notation in the following).

According to the composition law, we can find representatives for the maps involved such that

\[
\Phi_{X, Y_1, \eta, s} = (\tau^{-1} \Psi_{Z_1, \eta, s}, \Psi_{Z_2 \cup Z_3, \eta})
\]

\[
= (\tau^{-1} F_{Z_1, \eta, s}(\Theta^{-}), F_{Z_2 \cup Z_3, \eta}(\Theta^{-}))
\]

\[
= 1 \otimes \prod (\tau^{-1} F_{Z_1, \eta, s}(\Theta^{-}), F_{Z_2, \eta} \circ F_{Z_3, \eta}(\Theta^{-})). \tag{20}
\]

Similarly,

\[
\Phi_{X, Y_2, \eta, s} = \prod \otimes 1 (\tau^{-1} F_{Z_2, \eta} \circ F_{Z_1, \eta}^{-1}(\Theta^{-}), F_{Z_3, \eta}^{-1}(\Theta^{-})). \tag{21}
\]

Thus, we can consider the quantity

\[
\Phi := (\tau^{-1} F_{Z_1, \eta}^{-1}(\Theta^{-}), F_{Z_2, \eta} \circ F_{Z_3, \eta}(\Theta^{-})) = (\tau^{-1} F_{Z_2, \eta} \circ F_{Z_1, \eta}^{-1}(\Theta^{-}), F_{Z_3, \eta}^{-1}(\Theta^{-})),
\]

where the second equality uses duality and the analog of Lemma 7.9 in the perturbed case. Here we also note that the pairings above take values in

\[
\mathcal{K}(Z_1, \eta) \otimes_{\mathcal{R}_{Y_1, \eta}} \mathcal{K}(Z_2 \cup Z_3, Y_2, \eta) \quad \text{and} \quad \mathcal{K}(Z_1 \cup Z_2, Y_1, \eta) \otimes_{\mathcal{R}_{Y_2, \eta}} \mathcal{K}(Z_3, \eta),
\]

which are mutually isomorphic to the Novikov completion of

\[
\mathbb{Z} \left[ \frac{K(Z_1) \oplus K(Z_2) \oplus K(Z_3)}{H^1(Y_1) \oplus H^1(Y_2)} \right].
\]
with respect to (the linear function on \(K(Z_1) \oplus K(Z_2) \oplus K(Z_3)\) induced by) \(\eta\). Just as in Lemma 2.7, there is an isomorphism

\[
\frac{K(Z_1) \oplus K(Z_2) \oplus K(Z_3)}{H^1(Y_1) \oplus H^1(Y_2)} \cong \ker[\rho_1 \oplus \rho_2 \oplus \rho_3] : H^2(X) \to H^2(Z_1) \oplus H^2(Z_2) \oplus H^2(Z_3),
\]

where \(\rho_i\) is the restriction \(H^2(X) \to H^2(Z_i)\). We denote the above group by \(K(X; Y_1, Y_2)\) and the Novikov completion of \(\mathbb{Z}[K(X; Y_1, Y_2)]\) with respect to \(\eta\) by \(\mathcal{K}(X; Y_1, Y_2, \eta)\); this is a module for \(\mathcal{R}_{Y_1, \eta}\) and \(\mathcal{R}_{Y_2, \eta}\) via the coboundary map \(H^1(Y_1) \oplus H^1(Y_2) \to H^2(X)\) in the Mayer–Vietoris sequence arising from the decomposition \(X = (Z_1 \cup Z_3) \cup Y_1 \cup Y_2, Z_2\). For this to make sense with the above identifications, we adopt the convention that in this situation the map \(H^1(Y_2) \to H^2(X)\) is signed oppositely from the one that arises when considering the single cut along \(Y_2\); this is to account for the conjugate modules appearing above.

To understand the situation more concretely, consider the diagram:

\[
\begin{array}{ccc}
H^2(X) & \xrightarrow{\rho_1 \oplus \rho_{23}} & H^2(Z_1) \oplus H^2(Z_2 \cup Z_3) \\
\downarrow & & \downarrow 1 \oplus \rho_2 \oplus \rho_3 \\
H^2(Z_1) \oplus H^2(Z_2) & \oplus & H^2(Z_3)
\end{array}
\]

The kernel of the composition of the two maps is \(K(X; Y_1, Y_2)\), while the kernel of the horizontal map \(\rho_1 \oplus \rho_{23}\) is \(K(X, Y_1)\); this shows \(K(X, Y_1) \subset K(X; Y_1, Y_2)\) (and there is a corresponding diagram showing \(K(X, Y_2) \subset K(X; Y_1, Y_2)\)). On the other hand, the kernel of the composition is the preimage under \(\rho_1 \oplus \rho_{23}\) of the kernel of \(1 \oplus \rho_2 \oplus \rho_3\). The latter is clearly the image \(\im(\delta): H^1(Y_2) \to H^2(Z_2 \cup Z_3)\). Let \(\mathcal{S} \subset K(X; Y_1, Y_2)\) be a complete set of coset representatives for \(K(X, Y_1) \subset K(X; Y_1, Y_2)\). Thus we can think of \(\mathcal{S}\) as a collection of lifts to \(H^2(X)\) of the members of the image of \(H^1(Y_2) \to H^2(Z_2 \cup Z_3)\) that lie in the range of \(\rho_{23}\). In particular, for a given \(s \in \mathcal{S}\) the spin\(^c\) structure \(s + s\) has the same restrictions to \(Z_1, Z_2\) and \(Z_3\) as does \(s\), but the restriction to \(Z_2 \cup Z_3\) differs from that of \(s\).

Now, according to (20) and (21), the invariants \(\Phi_{X, Y_1, \eta, s}\) and \(\Phi_{X, Y_2, \eta, s}\) are the images of \(\bar{\Phi}\) under the homomorphisms \(1 \otimes \Pi\) and \(\Pi \otimes 1\), respectively. The projections \(\Pi\) are the restriction homomorphisms (in the sense of Lemma 8.2) associated to inclusions \(K(Z_1 \cup Z_2) \to K(Z_1 \cup Z_2, Y_1)\) (cf the discussion before Theorem 2.9). It is not hard to see that under the identifications above, \(1 \otimes \Pi\) is a restriction homomorphism associated to the inclusion \(K(X, Y_1) \to K(X; Y_1, Y_2)\). When thinking of \(1 \otimes \Pi\) in

*Geometry & Topology, Volume 12 (2008)*
this way, we will write it as \( \Pi_1: K(X; Y_1, Y_2) \to K(X, Y_1, \eta) \); and similarly write \( \Pi \otimes 1 \) as \( \Pi_2: K(X; Y_1, Y_2, \eta) \to K(X, Y_2, \eta) \).

Suppose we are given a spin\(^c\) structure \( s \) and an element \( \eta \in S \). We can write \( s \) as a lift \( \tilde{\delta}h \) of an element \( \delta h \in \text{im}(\delta: H^1(Y_2) \to H^2(Z_2 \cup Z_2)) \), and according to Theorem 2.9 and the sign convention on the coboundary operator mentioned previously, we have

\[
\Phi_{X,Y_1,\eta,s+s} = (\tau^{-1} F_{Z_1,\eta,s}(\Theta^-), F_{Z_2 \cup Z_3,\eta,s-\delta h}(\Theta^-))
\]

\[
= 1 \otimes \Pi_1(\tau^{-1} F_{Z_1,\eta,s}(\Theta^-), F_{Z_2,\eta,s} \circ e^h \cdot F_{Z_3,\eta,s}(\Theta^-))
\]

\[
= \Pi_1(\tau^{-1} F_{Z_2,\eta,s} \circ F_{Z_1,\eta,s}(\Theta^-), e^h \cdot F_{Z_3,\eta,s}(\Theta^-))
\]

\[
= \Pi_1(e^{-h} \cdot \tilde{\Phi})
\]

where we can use the same representatives for the maps involved as in (20).

The above can be interpreted as follows. The “two-cut invariant” \( \tilde{\Phi} \) is an integer-valued function on the group \( K(X; Y_1, Y_2) \), whose values on each coset \( K(X, Y_1) + s \) are equal to the values of the one-cut invariant \( \Phi_{X,Y_1,\eta,s+s} \). Indeed, (20) indicates that the restriction of \( \tilde{\Phi} \) to the subgroup \( K(X, Y_1) \) is equal to \( \Phi_{X,Y_1,\eta,s} \), while the above calculation indicates that after translating \( \Phi \) by \(-h\) and restricting, we obtain \( \Phi_{X,Y_1,\eta,s+s} \). Thus, with appropriate choices of representatives,

\[
\tilde{\Phi} = \sum_{s \in S} s \cdot \Phi_{X,Y_1,\eta,s+s},
\]

thinking of both sides as members of the Novikov ring \( K(X; Y_1, Y_2) \).

An entirely analogous discussion holds for the one-cut invariant arising from \( Y_2 \), which yields the following.

**Lemma 8.16** Suppose \( X \) is given with two disjoint cuts \( Y_1 \) and \( Y_2 \) that are allowable for a class \( \eta \in H^2(X; \mathbb{R}) \), and whose orientations are compatible. Then for a spin\(^c\) structure \( s \) on \( X \), \( \Phi_{X,Y_1,\eta,s} \) and \( \Phi_{X,Y_2,\eta,s} \) contain the same information in the following sense.

Let \( K(X; Y_1, Y_2) \) be as above, and let \( S_1 \) and \( S_2 \) be complete sets of coset representatives for \( K(X, Y_1) \) and \( K(X, Y_2) \) respectively in \( K(X; Y_1, Y_2) \). Then there are choices of representatives for the invariants \( \Phi_{X,Y_1,\eta,s+s_i} \) (for \( s_i \in S_i \)) such that

\[
\sum_{s_i \in S_1} s_1 \cdot \Phi_{X,Y_1,\eta,s+s_1} = \sum_{s_2 \in S_2} s_2 \cdot \Phi_{X,Y_2,\eta,s+s_2},
\]

as members of \( K(X; Y_1, Y_2) \).

\( \square \)
This implies, for example, that the collection of values (coefficients) taken by $\Phi_{X,Y_1,\eta,s}$ for various $s$ ranging through the collection \{s_0 + k \mid k \in K(X; Y_1, Y_2)\} is the same as that of $\Phi_{X,Y_2,\eta,s}$, though of course the above also means that the identification between the coefficients can be made to be equivariant with respect to the affine structure on $K(X; Y_1, Y_2)$.

Finally we obtain the following, which is a restatement of Theorem 1.6 from the introduction. It should be seen as a generalization of Theorem 7.6 that allows us to calculate Ozsváth–Szabó invariants using essentially any cut $Y$, if we can find an appropriate perturbation.

**Theorem 8.17** Let $X$ be a closed oriented 4–manifold with $b^+(X) \geq 2$, and $Y \subset X$ a connected submanifold determining a decomposition $X = Z_1 \cup_Y Z_2$, where $Z_i$ are 4–manifolds with boundary. Fix a class $\eta \in H^2(X; \mathbb{R})$, and assume that $Y$ is an allowable cut for $\eta$. If $b^+(Z_1)$ and $b^+(Z_2)$ are not both 0, then for any spin$^c$ structure $s$ on $X$ and element $\alpha \in \mathcal{A}(X)$,

$$
\sum_{\tau \in K(X,Y)} \Phi_{X,s+\tau}(\alpha) \cdot c' = \Phi_{X,Y,\eta,s}(\alpha) = (\tau^{-1} \Psi_{Z_1,\eta,s}(\alpha_1), \Psi_{Z_2,\eta,s}(\alpha_2))
$$

up to sign and multiplication by an element of $K(X,Y)$, where $\alpha_1 \otimes \alpha_2 \mapsto \alpha$ as before. If $b^+(Z_1) = b^+(Z_2) = 0$ then the same is true after possibly replacing $\eta$ by another class $\tilde{\eta}$, where $\tilde{\eta}|_{Z_i} = \eta|_{Z_i}$ for $i = 1, 2$.

**Proof** If both $b^+(Z_1) \geq 1$ and $b^+(Z_2) \geq 1$ then this follows from Lemma 8.14. Assume, therefore, that $b^+(Z_1) = 0$. We wish to find a cut $Y'$ for $X$ such that (1) $Y'$ is disjoint from $Y$, and (2) in the decomposition $X = Z'_1 \cup_Y Z'_2$, we have $b^+(Z'_i) \geq 1$ for $i = 1, 2$.

To find $Y'$, first consider the restriction $\eta|_Y$. Since $Y$ is allowable for $\eta$ and $b^+(Z_1) = 0$, we must have $\eta|_Y \neq 0 \in H^2(Y; \mathbb{R})$. Hence we can find a surface $\Sigma \subset Y$ such that $\int_{\Sigma} \eta \neq 0$, and since $\eta$ is defined on $X$, we infer $[\Sigma]$ is nonvanishing in $H_2(X; \mathbb{Z})$. Clearly $\Sigma \cdot \Sigma = 0$. Let $S$ be an embedded surface in $X$ intersecting $\Sigma$ transversely in a single point; then $[\Sigma], [S]$ determine a direct summand of the intersection matrix of $X$ having one positive and one negative eigenvalue. Let $N$ be a tubular neighborhood of $S$ in $X$; then $Y$ separates $N$ into two components $N_1 \cup N_2$, with $N_i \subset Z_i$. Let $\tilde{Z}_1$ be obtained by adding a collar $Y \times [0, \epsilon] \subset Z_2$ to $Z_1$, and set $Z'_1 = \tilde{Z}_1 \cup N_2$. Thus $Y' = \partial Z'_1$ is obtained by pushing $Y$ slightly into $Z_2$ and attaching the boundary of $N_2$.

Since $\Sigma \cup S \subset Z'_1$ we see $b^+(Z'_1) = 1$; on the other hand, the complement $Z'_2 = X \setminus Z'_1$ has $b^+(Z'_2) = b^+(Z_2)$. There are several cases to distinguish.

*Geometry & Topology, Volume 12 (2008)*
Case 1 \((b^+(Z'_2) \geq 1)\) Here we are done, by Lemma 8.14 and Lemma 8.16. Indeed, Lemma 8.14 shows that the invariants calculated from \(Y'\) are the Ozsváth–Szabó invariants, while Lemma 8.16 implies that the invariants calculated from \(Y\), taken over all spin\(^c\) structures, can be made to correspond in an equivariant way to those calculated from \(Y'\).

Case 2 \((b^+(Z'_2) = 0, \text{ but } \eta|_{Y'} \neq 0)\) Then \(Y'\) is still an allowable cut for \(\eta\) and disjoint from \(Y\), so Lemma 8.16 applies. We can now run the construction above with \(Z'_2\) playing the role of \(Z_1\); the result is a new cut \(Y''\), disjoint from \(Y'\), with \(b^+(Z''_i) \geq 1\) for \(i = 1, 2\). Lemma 8.16 implies that the invariants calculated from \(Y, Y', \text{ and } Y''\) agree, while Lemma 8.14 shows that the invariants calculated from \(Y''\) are the Ozsváth–Szabó invariants.

Case 3 \((b^+(Z'_2) = 0 \text{ and } \eta|_{Y'} = 0)\) Let \(\bar{\eta} = \eta + \text{PD}_X[\Sigma]\), where \(\text{PD}_X[\Sigma]\) denotes the image in real cohomology of the Poincaré dual of \([\Sigma]\) in \(H^2(X; \mathbb{R})\). Then it is easy to see that \(\bar{\eta}|_{Y'} \neq 0\), so that \(Y'\) is an allowable cut for \(\bar{\eta}\). Note that since the classes \(\bar{\eta}\) and \(\eta\) differ by an element in the image of \(\delta\): \(H^1(Y; \mathbb{R}) \to H^2(X; \mathbb{R})\), they agree on \(Z_1\) and \(Z_2\). Running the preceding proof with \(\bar{\eta}\) in place of \(\eta\) we end in case 2 above, hence the conclusion of the theorem holds with the modified perturbation.

Note that in case 3 of the proof, it works just as well to take \(\bar{\eta} = \eta + \epsilon \text{PD}_X[\Sigma]\), where \(\epsilon\) is an arbitrary nonzero real number. Thus Theorem 8.17 could be rephrased to say that when \(b^+(X) \geq 2\), the perturbed Ozsváth–Szabó invariants are equal to the ordinary Ozsváth–Szabó invariants when calculated with respect to a cut \(Y\) that is allowable for a “generic” class \(\eta \in H^2(X; \mathbb{R})\).

The preceding results provide sufficient understanding of the dependence of \(\Phi_{X,Y,\eta,s}\) on \(Y\) for our purposes. We do not study the dependence of the perturbed invariants on \(\eta\) here.

9 Heegaard Floer homology of a surface times a circle

From the general considerations of the preceding sections, we turn now to the problem mentioned in the introduction of determining the behavior of Ozsváth–Szabó invariants under fiber sum. Since a fiber sum along surfaces with trivial normal bundle is obtained by gluing two manifolds together along the product of the summing surface \(\Sigma\) with a circle, and the relative invariants of the pieces take values in the Floer homology of the latter manifold, we will need a fairly detailed understanding of that Floer homology.

This section is devoted to the calculation of the perturbed Heegaard Floer homology groups of \(\Sigma \times S^1\), for a particular choice of perturbation \(\eta\). Indeed, our choice of \(\eta\) is
induced by the cobordism $\Sigma_g \times D^2 - D^4$. The main input for this computation comes from [3] where we developed most of the technical tools required. We start this section by elucidating the new phenomena associated with working with twisted coefficients in surgery exact sequences.

### 9.1 Exact sequences with twisted coefficients

Let $K$ be a nullhomologous knot in a 3–manifold $Y$. Following typical notation in the subject, we write $Y_\ell = Y_\ell(K)$ for the 3–manifold obtained by $\ell$–framed surgery on $K$. As described in [11], there are exact sequences relating $HF^+$ (or $\widehat{HF}$) of the two triples of three 3–manifolds $(Y_0, Y, Y_n)$ and $(Y_0, Y, Y)$ with $n > 0$ but otherwise arbitrary:

\[
\cdots \xrightarrow{G} HF^+(Y_0, [s_k]) \xrightarrow{H} HF^+(Y, s) \xrightarrow{F} HF^+(Y_n, s_k) \xrightarrow{G} \cdots
\]

(22)

\[
\cdots \xrightarrow{G} HF^+(Y_0, [s_k]) \xrightarrow{H} HF^+(Y, s) \xrightarrow{F} HF^+(Y_n, s_k) \xrightarrow{G} \cdots
\]

By abuse of notation we have labeled the maps appearing in the two sequences by the same letters although they are of course different functions. The map $F$: $HF^+(Y, s) \to HF^+(Y_n, s_k)$ will be of special interest below and we proceed by first providing more details concerning its definition as well as explaining the notation from (22).

Let $W_n$ be the cobordism from $Y$ to $Y_n$ obtained by attaching a $-n$–framed 2–handle to $Y \times [0, 1]$ along $K \times \{0\}$. Let $\sigma \subset Y$ be a Seifert surface of $K$ and let $S \subset W_n$ be the surface obtained by capping off $\sigma \times \{1\}$ with the core of the attaching 2–handle. Given a spin–structure $s \in \text{Spin}^c(Y)$ let $s_k \in \text{Spin}^c(Y_n)$ be the spin–structure on $Y_n$ which is spin–cobordant to $s$ via $(W_n, \tau_{k,0})$ where $\tau_{k,0} \in \text{Spin}^c(W_n)$ is uniquely determined by $\tau_{k,0}|_Y = s$, $\langle c_1(\tau_{k,0}), [S] \rangle = 2k - (2\ell - 1)n$ and $k \in \{0, 1, ..., n-1\}$. By $[s_k]$ we denote the preimage $Q_{\pm}^{-1}(s_k)$ of a surjective map $Q_{\pm}: \text{Spin}^c(Y_0) \to \text{Spin}^c(Y_{\pm n})$ defined in [11, Theorem 9.19] whose details need not concern us save the fact that when $n \gg 0$ this preimage includes at most a single spin–structure whose Floer homology $HF^+(Y_0, t)$ is nontrivial. By writing $HF^+(Y_0, [s_k])$ we mean the direct sum of $HF^+(Y_0, t)$ over all spin–structures $t \in [s_k]$.

The map $F$ from (22) is a sum

(23) $F = \sum_{\ell \in \mathbb{Z}} F_{\ell}$, where

$F_{\ell}: HF^+(Y, s) \to HF^+(Y_n, s_k)$

is the homomorphism induced by $(W_n, \tau_{k,\ell})$.

---

1Every spin–structure $\tau \in \text{Spin}^c(W_n)$ with $\tau|_Y = s$ and $\tau|_{Y_n} = s_k$ is of the form $\tau = \tau_{k,\ell}$ for some $\ell \in \mathbb{Z}$. 

*Geometry & Topology, Volume 12 (2008)*
Recall that when $c_1(s)$ is torsion both $\text{HF}^+(Y, s)$ and $\text{HF}^+(Y_{\pi}, s_k)$ come equipped with an absolute $\mathbb{Q}$–grading $\text{gr}$ lifting the relative $\mathbb{Z}$–grading $gr$ (cf [15; 9]). With respect to the absolute grading $\text{gr}$ the degrees of the maps $F_\ell$ on homogeneous elements are

$$\text{deg} F_\ell = \frac{1}{4} \left( 1 - \frac{(2k - (2\ell - 1)n)^2}{n} \right)$$

(24)

This function attains its maximum at $\ell = \frac{1}{2} - \frac{k}{n}$, though of course $\ell$ is constrained to be an integer. When $k \neq 0$ there is therefore a unique value of $\ell$ corresponding to the maximal degree shift, while for $k = 0$ the maximum is attained for both $\ell = 0, 1$ (granted that $n > 1$).

To state the version of the sequence for twisted coefficients we first introduce some more notation. Write $W_0: Y \to Y_0$ for the surgery cobordism; then it is a simple matter to calculate that $K(W) \subset H^2(W, \partial W; \mathbb{Z})$ is infinite cyclic, generated by the Poincaré dual of the capped-off Seifert surface $S_W \subset W_0$. The group ring $\mathbb{Z}[K(W)]$ is then isomorphic to the ring $L(t)$ of Laurent polynomials in a single variable $t$, with $R_{Y_0}$–module structure induced by the natural homomorphism $H^1(Y_0) \to K(W) = H^1(Y_0)/H^1(W)$. With the choice of Seifert surface $\sigma$ fixed, we can think of $\mathbb{Z}[K(W)] = L(t)$ more concretely as follows. Let $\hat{\sigma} \subset Y_0$ be the surface obtained by capping off $\sigma$ with the surgery disk, and take $t = \text{PD}([\hat{\sigma}]) \in H^1(Y_0; \mathbb{Z})$. Then let $L(t) = \mathbb{Z}[t, t^{-1}]$ be the ring of Laurent polynomials in $t$; equivalently $L(t)$ is the group ring on the subgroup of $H^1(Y_0)$ generated by $t$. There is a natural homomorphism $\mathbb{Z}[H^1(Y_0)] \to L(t)$ induced by the map $\alpha \mapsto [\alpha, [K]] \cdot t$, or in multiplicative notation $\alpha \mapsto t^{[\alpha, [K]]}$, corresponding to the map $R_{Y_0} \to \mathbb{Z}[K(W)]$ above. (Here $[K]$ indicates the homology class in $H_1(Y_0)$ coming from the core of the surgery torus.) Observe that if $t \in \text{Spin}(Y_0)$ is a spin structure whose Chern class is dual to a multiple of $[\hat{\sigma}]$ then as in Proposition 3.5, $L(t)$ is naturally a graded module for $R_{Y_0, t}$ with $\text{gr}_{t}(t) = -\{c_1(t) \cup t, [Y_0]\}$.

More generally, suppose $s \in \text{Spin}(Y)$ is a spin structure on the original 3–manifold, and $M$ is a graded module for $R_{Y, s}$. Then the surgery cobordism $Y \to Y_0$, equipped with some spin structure, induces a graded module $M \otimes_{R_{Y, s}} \mathbb{Z}[K(W)]$ for $R_{Y_0, t}$ that we denote by $M[t^{\pm 1}]$, where $H^1(Y)$ acts trivially on $L(t)$.

With this understood, the next theorem is a slight generalization of Theorem 9.21 from Section 9.6 in [11]. Indeed, the proof of that theorem goes through verbatim with only notational modifications to yield:
Theorem 9.1  Let \( Y \) be a three manifold, \( K \) a nullhomologous knot in \( Y \) and \( M \) an \( R_Y \)-module. Then for any \( n > 0 \) there are long exact sequences of \( R_Y \otimes \mathbb{Z}[U] \)-modules for the Heegaard Floer homology groups with twisted coefficients:

\[
\ldots \xrightarrow{G} HF^+(Y_0, [s_k]; M[t^{\pm 1}]) \xrightarrow{H} HF^+(Y, (s); M)[t^{\pm 1}] \xrightarrow{F} HF^+(Y_{-n}, (s_k); M)[t^{\pm 1}] \xrightarrow{G} \ldots
\]

\[
\ldots \xrightarrow{G} HF^+(Y_0, [s_k]; M[t^{\pm 1}]) \xrightarrow{H} HF^+(Y, (s); M)[t^{\pm 1}] \xrightarrow{F} HF^+(Y, (s_k); M)[t^{\pm 1}] \xrightarrow{G} \ldots
\]

The analogous sequences for \( \widehat{HF} \) are also exact.

We shall refer to the above sequences as the negative \( n \) and positive \( n \) surgery sequences respectively. As in (22) we abuse notation by labelling the maps in both sequences by the same letters. It is worthwhile to single out a case of special interest later on, namely the choice of \( M = \mathbb{Z} \) with trivial \( R_Y \)-module structure. In this case the negative \( n \) sequence becomes

\[
\ldots \xrightarrow{G} HF^+(Y_0, [s_k]; L(t)) \xrightarrow{H} HF^+(Y, (s); t^{\pm 1}] \xrightarrow{F} HF^+(Y_{-n}, (s_k); M)[t^{\pm 1}] \xrightarrow{G} \ldots
\]

The fact that the Novikov ring \( R_{Y_0, \eta} \) is flat over \( R_Y \) implies the following, by tensor product of (25) with \( R_{Y_0, \eta} \).

Corollary 9.2  Suppose \( \eta_0 \in H^2(W_0; \mathbb{R}) \) is given, and the image \( \eta \) of \( \eta_0 \) under the map \( H^2(W_0; \mathbb{R}) \to H^2(Y_0; \mathbb{R}) \) satisfies \( \langle \eta \cup t, [Y_0] \rangle > 0 \). Then for any \( n > 0 \) there is a long exact sequence

\[
\ldots \xrightarrow{G} HF^+(Y_0, [s_k]; L(t)) \xrightarrow{H \otimes 1} HF^+(Y, (s); t^{\pm 1}] \otimes R_Y R_{Y_0, \eta} \xrightarrow{F \otimes 1} HF^+(Y_{-n}, (s_k); t^{\pm 1}] \otimes R_Y R_{Y_0, \eta} \xrightarrow{G \otimes 1} \ldots
\]

where \( L(t) \) denotes the ring of Laurent series in \( t \).

Indeed, it is not hard to see using Lemma 8.2 that the map \( H^1(Y_0) \to K(W_0) \) induces a homomorphism of Novikov rings \( R_{Y_0, \eta} \to K(W_0, \eta) \) under the hypotheses above, and that in fact \( K(W_0, \eta) \cong L(t) \).

There is a straightforward relationship between the exact sequences (22) and (25).
Proposition 9.3 Let $K$ be a nullhomologous knot in $Y$ and let $F: HF^+(Y, s) \to HF^+(Y_{-n}, s_k)$ and $F: HF^+(Y, s)[t^{\pm 1}] \to HF^+(Y_{-n}, s_k)[t^{\pm 1}]$ be the maps appearing in the exact sequences (22) and (25) respectively. Let $F_i$ be the components of $F$ as in (23). Then

$$F = \sum_{\ell \in \mathbb{Z}} F_{\ell} \otimes t^\ell$$

up to sign and overall multiplication by a power of $t$.

Moreover, when $s$ is torsion and for a given fixed number $d_0 \in \mathbb{Q}$, the only nonzero terms in the restriction of $F$ to $HF^+_{\leq d_0}(Y, s)$ are those for which $\ell = 0$ or $1$, for any sufficiently large $n$.

Proof The homomorphisms in both sequences are defined by counts of holomorphic triangles in appropriate Heegaard triple-diagrams, and the stated relationship between $F$ and $F$ follows from elementary considerations in these diagrams. Indeed, in notation from [11] (also [16]), the map in the twisted sequence can be written as

$$F([x, i]) = \sum_{\psi \in \pi_2(x, \Theta, y)} \#M(\psi)[y, i - n_z(\psi)] \cdot t^{n_\gamma(\psi)}$$

where the sum is over homotopy classes of triangles $\psi$ in a diagram $(\Sigma, \alpha, \beta, \gamma, z)$ describing the natural cobordism $Y \to Y_{-n}$. In this situation we are using twisted coefficients on $Y_{-n}$ constructed by fixing a reference point $\tau$ lying on the surgery circle $\gamma_\tau$, such that the boundary operator in the twisted chain complex for $Y_{-n}$ records (in the power of $t$) the intersection of the $\gamma$–component of a holomorphic disk with the subvariety $V = \gamma_1 \times \cdots \times \gamma_{g-1} \times \{\tau\} \subset T_\gamma \subset \text{Sym}^g(\Sigma)$. (This formal device induces trivially twisted coefficients on $Y_{-n}$.) In the formula above, the power $n_\gamma(\psi)$ is similarly the intersection of the $\gamma$–component of the boundary of $\psi$ with $V$.

The first claim of the proposition amounts to the fact that the power of $t$ appearing above determines and is determined by the value $\langle c_1(s_z(\psi)), H(P) \rangle$, where $H(P)$ is the 2–dimensional homology class of the triply periodic domain $P$ corresponding to the generator of the 2–dimensional homology of the surgery cobordism. This in turn follows easily from inspection of the Heegaard triple itself, together with the expression for $\langle c_1(s_z(\psi)), H(P) \rangle$ in terms of data on the Heegaard diagram obtained by Ozsváth and Szabó (Proposition 6.3 of [15]).

To see the remaining claim, recall that the homomorphism $F_{\ell}$ (corresponding to the spin$^c$ structure on the cobordism with $\langle c_1(\tau_{k, \ell}), [S] \rangle = 2k - (2\ell - 1)n$) induces a shift.
in degree given by (24). In particular we have
\[ \deg F_\ell - \deg F_0 = 2k\ell - \ell(\ell - 1)n \]
\[ \deg F_\ell - \deg F_1 = 2k(\ell - 1) - \ell(\ell - 1)n, \]
and so for \( \ell \neq 0, 1 \), the degree shift of \( F_\ell \) can be made arbitrarily large by choosing \( n \) large. The result follows since the grading of \( HF^+ \) is bounded below. \( \square \)

As an example, let us consider the Floer homology of the 3–torus \( T^3 \), in the torsion spin\(^c\) structure. We can realize \( T^3 \) as the result of 0–surgery on each component of the Borromean rings (Figure 1 below), and if we take \( K \) to be one component of that link, then \( T^3 = Y_0(K) \) where \( Y = \#^2 S^1 \times S^2 \). It is well-known that
\[
HF^+(\#^2 S^1 \times S^2, s) \cong \Lambda^* H^1(\#^2 S^1 \times S^2; \mathbb{Z}) \otimes T_n,
\]
where \( T_n \) is the \( \mathbb{Z}[U] \)–module \( \mathbb{Z}[U, U^{-1}] / U \cdot \mathbb{Z}[U] \), graded so that the homogeneous factor of lowest degree is in dimension \( n \). It can also be shown that for sufficiently large \( n \) there is an isomorphism
\[
HF^+_d(Y_{-\tau}, s_0) \cong \begin{cases} \mathbb{Z} \oplus \mathbb{Z} & d \geq \tau \\ 0 & d < \tau \end{cases}
\]
where \( \tau = \frac{1}{4}(1 - n) \) (this follows from results in [10], cf also the discussion in the next subsection).

Hence the surgery sequence (25) appears as:
\[
\begin{array}{ccc}
\mathbb{Z}[t^{\pm 1}] & \mathbb{Z}[t^{\pm 1}] & \mathbb{Z}^2 \\
\mathbb{Z}[t^{\pm 1}] & \mathbb{Z}[t^{\pm 1}] & \mathbb{Z}^2 \\
\mathbb{Z}[t^{\pm 1}] & \mathbb{Z}[t^{\pm 1}] & \mathbb{Z}^2 \oplus \mathbb{Z}[t^{\pm 1}] \\
\mathbb{Z}[t^{\pm 1}] & 0 & 0
\end{array}
\]
Here we have arranged the columns “typewriter style,” so that the top-degree components of the homomorphisms between the groups map horizontally, with the map \( T^3 \to Y_{-\tau} \) moving to the next row of the array. Strictly, the groups along the row second from the bottom appear in degrees 0, \( \tau \), and \(-\frac{1}{2}\), respectively. Furthermore, we have chosen \( n \) large enough that only \( F_0 \) and \( F_1 \) are relevant for the displayed portion of the sequence (which continues upward indefinitely, repeating the top row above). The structure of the Floer homology of \( T^3 \) in large degrees can be deduced from the universal coefficients spectral sequence, or by using the description of \( F_0 \) and \( F_1 \) given in the following subsection. The \( U \)–equivariance of the sequence together
with some easy homological algebra then shows that $HF_{-1/2}^+(T^3)$ has the indicated form. Finally, we point out for future reference that the map

$$HF_{-1/2}^+(T^3, s_0; L(t)) \to HF_{-1}^+(\#^2 S^1 \times S^2, s)[t^{\pm 1}]$$

appearing above is induced by the surgery cobordism equipped with the torsion spin$^c$ structure, and corresponds to the projection $\mathbb{Z}^2 \oplus L(t) \to L(t)$.

9.2 A surface cross a circle: partially twisted coefficients

In this section we apply the general discussion from the previous section to the case of $Y = \#^2 g(S^1 \times S^2)$ and $K = K_g = \#^g B(0, 0)$ with $B(m, n)$ defined in Figure 1.

Let $s$ be the unique torsion spin$^c$ structure on $Y$. Since $HF^+$ is nonzero only for a finite set of spin$^c$–structures, when $n \gg 0$ there is only one spin$^c$ structure in the set $[s_k]$ having nontrivial $HF^+$, namely the unique spin$^c$–structure $s_k \in \text{Spin}^c(\Sigma_g \times S^1)$ with $c_1(s_k) = 2k \text{PD}([S^1])$. We shall take as perturbation the class $\eta = \text{PD}([S^1])$.  

Figure 1: The knot $B(m, n) \subset L(m, 1)#L(n, 1)$ with $m, n \in \mathbb{Z}$. (Note that $L(0, 1)$ is just $S^1 \times S^2$.)
which is easily seen to be the restriction of a class on the surgery cobordism $W_0: Y \to Y_0$.

With these choices of $Y, K, \sigma$ the maps $F_0, F_1: HF^+(Y, s) \to HF^+(Y-n, s_k)$ appearing in Proposition 9.3 have been made completely explicit by the results from [3; 10]. Before proceeding we describe these maps.

Let us use the shorthand $\Lambda^k$ and $\Lambda^*$ to denote $\Lambda^k H^1(\Sigma_g; \mathbb{Z})$ and $\Lambda^* H^1(\Sigma_g; \mathbb{Z})$ respectively. The reader familiar with knot Floer homology [10; 18] may recall that $\Lambda^{g+j}$ is just the knot Floer homology $\widehat{HF}(\#^B(0, 0), j)$, which is the homology of the associated graded complex arising from a filtration on the Heegaard Floer chain groups $\widehat{CF}$. Such a filtration is induced by any nullhomologous knot $K$ in a 3–manifold $Y$; here we specialize to the case $K = \#^B(0, 0)$. In fact, $K$ induces a filtration on all the Heegaard Floer chain complexes, in particular on $CF\infty$; the filtration level $j$ of a generator $[x,i]$ for $CF\infty$ can be calculated directly from a Heegaard diagram for $Y$ (suitably adapted to $K$), and is recorded in the notation $[x,i,j]$.

The function $[x,i,j] \mapsto i+j$ gives rise to another filtration on $CF\infty$, and thence a spectral sequence converging to $HF\infty(Y)$ whose $E^1$ term is $\widehat{HF}(Y, K) \otimes \mathbb{Z}[U, U^{-1}]$ (cf [10]). It is this object that is currently under consideration in the case $K = \#^B(0, 0)$; in the case at hand (ie, $K = \#^B(0, 0)$, with integral coefficients in all Floer homology), there are no further differentials in any of the spectral sequences.

We place the $\mathbb{Z}[U]$–module $\Lambda^* \otimes \mathbb{Z}[U, U^{-1}]$ in a 2–dimensional coordinate system by assigning $\Lambda^k \otimes U^\ell$ the coordinates $(-\ell, k-g-\ell)$ (see Figure 2 below). We equip the coordinate plane with a $\mathbb{Q}$–grading $\widehat{gr}: \mathbb{Z}^2 \to \mathbb{Q}$ by setting

$$\widehat{gr}(i,j) = i+j.$$  

In this description, the action of $U$ can be thought of as translation by $(-1,-1)$ (see again Figure 2); as usual it decreases grading by two. Following [10], we shall write

$$H\{\text{condition on } (i,j)\}$$

to denote the various $\mathbb{Z}[U]$ submodules and quotient modules of $\Lambda^* \otimes \mathbb{Z}[U, U^{-1}]$ obtained as a direct sum over all the terms in the coordinate system which reside at coordinates $(i,j)$ subject to the stated conditions. For example $H\{i < 0\}$ is the submodule $\Lambda^* \otimes (U \cdot \mathbb{Z}[U])$ and $H\{i \geq 0\}$ is the quotient module $\Lambda^* \otimes \mathcal{T}$, where $\mathcal{T} = \mathbb{Z}[U, U^{-1}]/U \cdot \mathbb{Z}[U]$. For $0 \leq d \leq g-1$ we define the $\mathbb{Z}[U]$–module $X(g,d)$ as

$$X(g,d) = \bigoplus_{i=0}^{d} \left( \Lambda^i \otimes \mathbb{Z} \frac{\mathcal{T}}{U^{i-d-1} \cdot \mathbb{Z}[U^{-1}]} \right).$$

While our definition of $X(g,d)$ differs slightly from that used by Ozsváth and Szabó in [10], it is not hard to see that they agree up to an isomorphism of relatively graded
Figure 2: A visual representation of $\Lambda^* \otimes \mathbb{Z}[U, U^{-1}]$ in the case of $g = 3$. The dot at coordinate $(x, y)$ represents the group $\Lambda^{g-x+y} \otimes U^{-x}$, two examples are indicated. The action of $U^\ell$ in this description of $\Lambda^* \otimes \mathbb{Z}[U, U^{-1}]$ is simply translation by $(-\ell, -\ell)$. The direct sum of the groups represented by the dots in the shaded triangle is $X(3, 2)$.

$\mathbb{Z}[U]$–modules. In fact, as was noted in [10], $X(g, d)$ is isomorphic as a relatively graded group to the homology of $\text{Sym}^d(\Sigma_g)$, the $d$–fold symmetric power of a genus $g$ surface. Indeed, the action of $U$ on $X(g, d)$ corresponds to the cap product with the Poincaré dual of $pt \times \text{Sym}^{d-1}(\Sigma_g)$ on $H_*(\text{Sym}^d(\Sigma_g))$.

In the notation above, $X(g, d)$ is isomorphic to

$$X(g, d) \cong H\{i \geq 0 \text{ and } j < d + 1 - g\}$$

as a $\mathbb{Z}[U]$–module; see Figure 2 for a visual representation. We shall refer to this identification as the standard embedding of $X(g, d)$ into $\Lambda^* \otimes \mathbb{Z}[U, U^{-1}]$. We shall encounter “nonstandard embeddings” of $X(g, d)$ as well; see Theorem 9.4 below.

It was shown in [10, Section 9] (as an instance of a general result on the relationship between the knot Floer homology of $K$ and the Floer homology of surgeries along $K$) that for $Y = \#^2 g S^1 \times S^2$ and $K = \#^g B(0, 0)$ as above, and $n \gg 0$, there are $\Lambda^* H_1(\Sigma_g; \mathbb{Z}) \otimes \mathbb{Z}[U]$–module isomorphisms

$$HF^+(Y, s) \cong H\{i \geq 0\} \quad \text{and} \quad HF^+(Y-n, s_k) \cong H\{i \geq 0 \text{ and } j \geq k\}$$

where the action of $\Lambda^* H_1(\Sigma_g; \mathbb{Z}) \cong \Lambda^* H_1(Y; \mathbb{Z})$ on $\Lambda^k \otimes U^\ell$ is given by

$$\gamma \cap (\alpha \otimes U^\ell) = t_\gamma \alpha \otimes U^\ell + (\text{PD}(\gamma) \wedge \alpha) \otimes U^{\ell+1}$$

*Geometry & Topology, Volume 12 (2008)*
for $\gamma \in H_1(\Sigma_g; \mathbb{Z})$ and $\alpha \in \Lambda^k$. Here $\iota_\gamma$ is contraction with $\gamma$ and $\text{PD}(\gamma)$ is the Poincaré dual of $\gamma$ taken on $\Sigma_g$. By virtue of (27) this action induces an action on $X(g, d)$. We shall refer to (29) as the standard action, and use the cap product notation $\cap$ to distinguish it from actions of first homology on Floer homology that need not be “standard” (we use the “dot” notation for the latter: $h.\xi$ for $h \in H_1$, $\xi \in HF^\circ$).

To describe the maps $F_0$, $F_1$: $H\{i \geq 0\} \rightarrow H\{i \geq 0 \text{ and } j \geq k\}$ (under the identifications (28)) we need a bit more notation. Let $e_1, \ldots, e_{2g}$ be a symplectic basis for $H_1(\Sigma_g; \mathbb{Z})$ and set $\omega = e_1 \wedge e_2 + \cdots + e_{2g-1} \wedge e_{2g} \in \Lambda^2 H_1(\Sigma_g; \mathbb{Z})$. For a given $\beta \in \Lambda^1$ define $\beta \cap: \Lambda^k \rightarrow \Lambda^{k-1}$ as contraction associated to $\omega$, ie

$$\beta \cap (\alpha_1 \wedge \ldots \wedge \alpha_k) = \sum_{\ell=1}^{k} (-1)^\ell \omega(\alpha_\ell, \beta) \alpha_1 \wedge \ldots \wedge \hat{\alpha}_\ell \wedge \ldots \wedge \alpha_k$$

where $\omega(\alpha_\ell, \beta)$ refers to the natural pairing $\Lambda^2 H_1(\Sigma_g) \otimes \Lambda^2 H(\Sigma_g) \rightarrow \mathbb{Z}$. The contraction $\cap$ defined this way extends readily to a contraction $\cap: \Lambda^m \otimes \Lambda^k \rightarrow \Lambda^{k-m}$ given by $(\beta_1 \wedge \ldots \wedge \beta_m) \cap (\alpha_1 \wedge \ldots \wedge \alpha_k) = \beta_1 \cap (\beta_2 \cap (\ldots (\beta_m \cap (\alpha_1 \wedge \ldots \wedge \alpha_k) \ldots ))).$ Let $\tilde{\ast}: \Lambda^k \rightarrow \Lambda^{2g-k}$ be the “Hodge–Lefschetz star operator” associated to $\omega$ and defined as

$$\tilde{\ast} \alpha = \frac{1}{g!} \alpha \cap \omega^g$$

where we have by abuse of notation used $\omega$ to also denote $e^1 \wedge e^2 + \cdots + e^{2g-1} \wedge e^{2g} \in \Lambda^2$, which is the dual of the symplectic form $\omega$ from earlier. Here $e^i \in H^1(\Sigma_g; \mathbb{Z})$, $i = 1, \ldots, 2g$ is the dual basis (with respect to the Kronecker pairing) of $e_i \in H_1(\Sigma_g; \mathbb{Z})$, ie $e^i(e_j) = \delta_{ij}$.

Let

$$\pi_k : H\{i \geq 0\} \rightarrow H\{i \geq 0 \text{ and } j \geq k\}$$

$$\pi_{i \geq 0} : \Lambda^* \otimes \mathbb{Z}[U, U^{-1}] \rightarrow H\{i \geq 0\}$$

$$\pi_{j \geq 0} : \Lambda^* \otimes \mathbb{Z}[U, U^{-1}] \rightarrow H\{j \geq 0\}$$

be the natural projection maps and let $J: H\{i \geq 0\} \rightarrow H\{j \geq 0\}$ be the map

$$J(xU^k) = \pi_j \geq 0 \left((-1)^{k+g-1} \exp(2\omega U) \cap (\tilde{\ast} x) U^{g-k} \right)$$

when $x \in \Lambda^k$, where we omit the tensor product signs and, by convention, contraction with $U^n$ is taken to mean multiplication by $U^{-n}$. This map was studied in detail in [3]; see Figure 3 for a pictorial explanation of $J$.

The results from [3] show that $F_0$, $F_1$: $H\{i \geq 0\} \rightarrow H\{i \geq 0 \text{ and } j \geq k\}$ are given by

$$F_0 = \begin{cases} \pi_k : k \leq 0 \\ \pi_k \circ (U^{-k} J) : k > 0 \end{cases} \quad \text{and} \quad F_1 = \begin{cases} \pi_k : k \leq 0 \\ \pi_k \circ (U^{-k} J) : k > 0 \end{cases}$$

Stanislav Jabuka and Thomas E Mark

Figure 3: A visual explanation of the map $J: H[i \geq 0] \to H[j \geq 0]$ (with $g = 3$), which is perhaps best understood as a perturbation of the star operator $\tilde{\tau}$. The latter maps an element at coordinate $(x, y)$ to an element at coordinate $(y, x)$. The action of $\exp(2\alpha U)\tilde{\tau}$, thought of as a formal sum, then “smears out” such an element along the line with slope $-1$ and passing through $(y, x)$, in such a way that the only nonzero terms are those lying to the right and below $(y, x)$. Thus, for example when $g = 3$, an element at coordinate $(0, 3)$ is mapped by $J$ to an element at coordinate $(3, 0)$ while an element at coordinate $(5, 3)$ is mapped to a sum of terms living at coordinates $(5, 3)$, $(4, 4)$ and $(3, 5)$.

With all these preliminaries out of the way and with our notation in place, we now turn to the actual calculations of the twisted Heegaard Floer groups of $\Sigma_g \times S^1$. The adjunction inequality implies that for any spin$^c$–structure $s$ on $\Sigma_g \times S^1$ which is not among the $s_k$, the associated Heegaard Floer groups $HF^+(\Sigma_g \times S^1, s; M)$ vanish (for any coefficient module $M$); the same is true for $s = s_k$ when $|k| \geq g$. The remaining spin$^c$–structures $s_k$ with $|k| \leq g - 1$ give rise to nontrivial Heegaard Floer groups as the next theorem explains.

**Theorem 9.4** Fix an integer $k$ with $|k| \leq g - 1$. If $k \neq 0$ choose $\Lambda$ to be either $L(t)$ or $L(t)$ and if $k = 0$ choose $\Lambda = L(t)$. Then the Heegaard Floer homology groups $HF^+(\Sigma_g \times S^1, s_k; \Lambda)$ are isomorphic to

$$HF^+(\Sigma_g \times S^1, s_k; \Lambda) \cong X(g, d) \otimes \Lambda$$

with $d = g - 1 - |k|$ as $\mathbb{Z}[H^1(\Sigma_g \times S^1; \mathbb{Z})] \otimes \mathbb{Z}[U]$–modules. The action of $\Lambda^*H_1(\Sigma_g; \mathbb{Z}) \subset \Lambda^*H_1(\Sigma_g \times S^1; \mathbb{Z})$ on $X(g, d)$ is induced by the standard action (29) under the nonstandard
embedding of \( X(g, d) \) into \( \Lambda^* H^1(\Sigma_g; \mathbb{Z}) \otimes \mathbb{Z}[U, U^{-1}] \otimes \Lambda \) given by

\[
x \mapsto x + \pi_{-|k|} \left( \sum_{\ell \geq 1} (-t U^{|k|} J)^\ell x \right).
\]

**Proof** The proof of the theorem follows slightly different arguments depending on whether \( k \neq 0 \) or \( k = 0 \). We first address the former.

**Case of \( k \neq 0 \)** For concreteness let us assume \( k < 0 \). Choose \( \Lambda = L(t) \) for now and consider the negative surgery exact sequence in twisted coefficients \((25)\). By Proposition 9.3 the map \( \bar{F} \) equals \( F_0 + tF_1 \) after restricting to \( HF^{+}_{\leq d_0}(Y) \) for suitably large \( d_0 \), once \( n \) is chosen sufficiently large (which we assume tacitly throughout).

It follows from the degree shift formula \((24)\) that \( \deg F_0 = \deg F_1 - 2k \) and thus \( \deg F_0 > \deg F_1 \) when \( k < 0 \). From the description of \( F_0 \) and \( F_1 \) above, \( F_0 \) is clearly surjective. Since \( \deg F_1 < \deg F_0 \) we see that \( \bar{F} \) is also surjective. Moreover, we claim that the kernel of \( \bar{F} \) is generated by elements of the form

\[
\ker(\bar{F}) = \left\{ x + \pi_k \left( \sum_{\ell \geq 1} (-t U^{-k} J)^\ell x \right) \mid x \in H \{i \geq 0 \text{ and } j < k \} \right\}
\]

Indeed, suppose \( \xi = \xi_0 + \xi_1 + \cdots \) is in \( \ker(\bar{F}) \), where \( \xi_j \) are the homogeneous terms in order of decreasing degree. Then certainly \( \xi_0 \in \ker(F_0) = \ker(\pi_k) = H \{i \geq 0 \text{ and } j < k \} \). On the other hand, if \( x \in H \{i \geq 0 \text{ and } j < k \} \), we can “build” an element of \( \ker(\bar{F}) \) from \( x \) by observing that \( F_0(x) = 0 \), while \( tF_1(x) = t \pi_k(U^{-k} J(x)) \). Thus replacing \( x \) by \( x - t \pi_k(U^{-k} J(x)) \), we obtain an element still annihilated by \( F_0 \), whose image under \( tF_1 \) is \(( -t(U^{-k} J))^2 x \). Continuing in this way, and using that since \( k < 0 \) the action of \( U^{-k} \) is nilpotent on any element of \( \Lambda^* \otimes \mathbb{Z}[U, U^{-1}] \), we eventually find an element killed by \( F_0 + tF_1 = \bar{F} \). This gives the identification above, and then projection onto the homogeneous term of highest degree establishes the isomorphism \( \ker(\bar{F}) \cong X(g, d) \) with \( d = g - 1 - |k| \). Since the sequence \((25)\) is equivariant with respect to the \( H_1(\Sigma_g; \mathbb{Z}) \)-action, the proposition (for the case \( k < 0 \) and \( \Lambda = L(t) \)) follows. The results with \( \Lambda = \mathcal{L}(t) \) follows from the result for \( L(t) \) by tensoring with \( \mathcal{R}_{Y_0, n} \) and using the flatness of \( \mathcal{R}_{Y_0, n} \) (cf Corollary 9.2). The case of \( k > 0 \) can be proved analogously, or by appeal to conjugation invariance (Theorem 8.10).

We note that the argument above shows that \( \bar{F} \) is surjective, and that if \( \xi \in \ker(\bar{F}) \) then the largest degree of a homogeneous term in \( \xi \) is bounded above (by \( g - 2 - 2|k| \)), independent of \( n \). Thus the restriction of \( \bar{F} \) to \( HF^{+}_{\leq d_0} \) above is permissible.
Case of $k = 0$  Consider once more the sequence (25) and again note that upon restriction to a given grading we may take $E = F_0 + tF_1$. The key difference from the case of $k \neq 0$ is that the degrees of $F_0$ and $F_1$ are now equal.

We begin by showing that $E$ is again surjective: for a given $y \in H[i \geq 0 \text{ and } j \geq 0]$ let $x_y \in H[i \geq 0] \otimes \Lambda_\eta$ be $x_y = \pi_{i \geq 0}(-iJ)^{\ell}y$. Then

$$E(x_y) = \pi_0(\text{id} + tJ)\left(\pi_{i \geq 0}(-iJ)^{\ell}y\right) = \pi_0(\text{id} + tJ)\left(\sum_{\ell \geq 0}(-iJ)^{\ell}y\right) = \pi_0(y) = y.$$  

This shows $F_0 + tF_1$ is surjective; the remaining terms in $E$ have strictly lower degree, hence $E$ is also surjective.

To determine the kernel of $E$ pick a kernel element $\xi = \xi_0 + \xi_1t + \xi_2t^2 + \ldots \in \ker(E)$. Such an element $\xi$ is then subject to the infinite system of equations (coming from the requirement $(F_0 + tF_1)(\xi) = 0)$:

$$\begin{align}  
\pi_0(\xi_0) &= 0 \\
\pi_0(\xi_1 + J(\xi_0)) &= 0 \\
&\vdots \\
\pi_0(\xi_k + J(\xi_{k-1})) &= 0 \\
&\vdots
\end{align}$$  

(30)

The equation $\pi_0(\xi_0) = 0$ implies $\xi_0 \in H[i \geq 0 \text{ and } j < 0]$. The second equation determines the $H[i \geq 0 \text{ and } j \geq 0]\text{-component of } \xi_1$ uniquely but imposes no condition on the $H[i \geq 0 \text{ and } j < 0]\text{-component of } \xi_1$. The same holds true for all $\xi_k$, $k \geq 1$:

- The $H[i \geq 0 \text{ and } j \geq 0]\text{-component of } \xi_k$ is determined by $\xi_{k-1}$.
- The $H[i \geq 0 \text{ and } j < 0]\text{-component of } \xi_k$ can be chosen arbitrarily.

In particular, as before there is an a priori upper bound on the degree of a kernel element and therefore it suffices to assume that $E = F_0 + tF_1$.

This immediately shows that the kernel of the map $E$ is isomorphic (but not equal!) to $H[i \geq 0 \text{ and } j < 0] \otimes \mathcal{L}(t)$. As the above system shows, the isomorphism from $H[i \geq 0 \text{ and } j < 0] \otimes \mathcal{L}(t)$ to $\ker(E) \subset H[i \geq 0] \otimes \mathcal{L}(t)$ is given by the $\mathcal{L}(t)$-equivariant map

$$\xi \mapsto \xi + \pi_0\left(\sum_{\ell \geq 1}(-iJ)^{\ell}\xi\right).$$

Remark 9.5 Consider the embedding \( X(g, d) \hookrightarrow \Lambda^*H^1(\Sigma_g; \mathbb{Z}) \otimes \mathbb{Z}[U, U^{-1}] \otimes \Lambda \) from Theorem 9.4:

\[
x \mapsto x - \pi_k \left( tU^{-k}Jx - (tU^{-k}J)^2x + (tU^{-k}J)^3x - \ldots \right)
\]

It follows from this expression that the induced action by \( H_1(\Sigma_g) \) on \( X(g, d) \) is standard in the lowest power of \( t \) but typically has nonzero “correction terms” involving higher powers of \( t \). However, when \( 3|k| > g - 2 \) then all of the terms \( (tU^{-k}J)^\ell \) for \( \ell \geq 1 \) lie in the kernel of \( \pi_k \) showing that in that range the \( \Lambda^*H_1(\Sigma_g; \mathbb{Z}) \)-action has no correction terms. This was already observed by Ozsváth–Szabó [10, Theorem 9.3] in the case of \( \mathbb{Z} \) coefficients (see also [3]).

Remark 9.6 The isomorphism \( HF^+(\Sigma_g \times S^1, s_k; \Lambda) \cong X(g, d) \otimes \Lambda \) from Theorem 9.4 does not extend to the case of \( k = 0 \) and \( \Lambda = L(t) \). With \( k = 0 \) and \( \Lambda = L(t) \) the infinite system (30) becomes a finite system which terminates with the equation \( \pi_0(J(\xi_m)) = 0 \) for some choice of \( m \in \mathbb{N} \). This equation breaks the symmetry of the system and imposes additional constraints not satisfied by all elements of the form \( \pi_0 \sum_{t \geq 0} (-tJ)^\ell x \) with \( x \in X(g, g - 1) \otimes L(t) \).

Remark 9.7 From the proof of the theorem, the homomorphism \( F \colon HF^+(Y, s; \Lambda) \to HF^+(Y_{-n}, s_k; \Lambda) \) is surjective in all cases, so that \( HF^+(\Sigma \times S^1, s_k; \Lambda) \) can be thought of as a submodule of \( HF^+(Y, s; \Lambda) = \bigoplus_{i \geq 0} \otimes \Lambda \). The latter carries a grading with respect to which \( t \in \Lambda \) (or \( L(t) \) or \( L(t) \)) carries degree 0, so we can use this to impose a similar grading on \( HF^+(\Sigma \times S^1, s_k; \Lambda) = X(g, d) \otimes \Lambda \). Equivalently, we grade the latter group by lifting the natural grading on \( X(g, d) \), induced by the standard embedding. This grading lifts the relative cyclic grading obtained by forgetting the grading on \( R_{Y_0} \) in the definition of twisted-coefficient Floer homology, and has the property, for example, that homogeneous summands are \( R_{Y_0} \)-submodules. However, it is no longer the case that the action by \( H_1(Y_0) \) decreases degree by 1, or is even homogeneous. We will refer to this alternative grading as the height in \( HF^+(\Sigma \times S^1, s_k; \Lambda) \).

In the next section we will have occasion to consider the relative Ozsváth–Szabó invariant of the 4–manifold \( \Sigma \times D^2 \), for which the following result is central.

Theorem 9.8 Consider the cobordism \( W \) from \( \Sigma_g \times S^1 \) to \( S^3 \) obtained by removing a small 4–ball from \( \Sigma_g \times D^2 \). For \( |k| \leq g - 1 \) let \( \tau_k \in \text{Spin}^c(W) \) be the unique spin\(^c\)–structure on \( W \) which restricts to \( s_k \) on \( \Sigma_g \times S^1 \). If \( k = 0 \) let \( \Lambda = L(t) \) and if \( k \neq 0 \) choose \( \Lambda \) to be either \( L(t) \) or \( L(t) \). Then the component of

\[
\mathcal{F}_k = F_{W, s_k} : HF^+(\Sigma_g \times S^1, s_k; \Lambda) \to HF^+(S^3) \otimes \Lambda
\]
mapping into the lowest-degree part $HF^+_0(S^3) \otimes \Lambda$ is given by projection onto the summand of lowest height, corresponding to $H \{(0, -g)\} \otimes \Lambda \cong \Lambda^0 H^1(\Sigma) \otimes U^0 \otimes \Lambda \subset X(g, d) \otimes \Lambda$.

**Proof.** We decompose the cobordism $W$ as $W = W_0 \cup W_1 \cup ... \cup W_{2g}$ where $W_0$ is the cobordism from $\Sigma_g \times S^1$ to $Y = \#^{2g}(S^1 \times S^2)$ obtained by attaching a 0-framed 2--handle to the latter along the knot $K_g$. The orientation on $W_0$ is the one that induces the orientations $\partial W_0 = -(\Sigma_g \times S^1) \cup Y$ on its boundary components. The cobordisms $W_i$, $i = 1, ..., 2g$ are obtained by the obvious 3--handle additions corresponding to the $2g$ 1--handles of $Y$.

As explained in Section 2.2, the map $F_k$ can be calculated by separately calculating the contribution from each of the maps $F_{W_i}$ induced by $W_i$ (the spin$^c$--structure on $W_i$ is the restriction of $\tau_k|_{W_i}$ which we omit from the notation for simplicity).

The map $F_{W_0}$ is just the map $H$ from the sequence (25): it maps $HF^+(\Sigma_g \times S^1, s_k; \Lambda)$ isomorphically onto the kernel of $F$. This kernel was explicitly identified in the proof of Theorem 9.4 and equals the image of the embedding of $H\{i \geq 0$ and $j < -|k|\} \otimes \Lambda \hookrightarrow \Lambda^* \otimes \mathbb{Z}[U^{-1}] \otimes \Lambda$ given by

$$x \mapsto x + \pi_k \left( \sum_{\ell \geq 1} (-iU^{-k} J^\ell) x \right)$$

Under the identification of $HF^+(\Sigma_g \times S^1, s_k; \Lambda)$ with $H\{i \geq 0$ and $j < -|k|\} \otimes \Lambda$ (Theorem 9.4 and (27)), this embedding precisely corresponds to the map $F_{W_0}$.

It is a simple matter to see that the homomorphism in Floer homology induced by the composition of 3--handle cobordisms $\#^{2g}(S^1 \times S^2) \to S^3$ is given by projection onto the lowest-degree factor (and shifting degree up by $g$). The result follows from the above description of the image of $HF^+(\Sigma \times S^1, s_k; \Lambda)$ in $HF^+(\#^{2g} S^1 \times S^2)$: indeed, the only elements of $HF^+(\Sigma_g \times S^1, s_k; \Lambda)$ having any component in the lowest-degree part of $HF^+(\#^{2g} S^1 \times S^2)$ are those in lowest height.

**9.3 A surface cross a circle: universally twisted coefficients**

It will be useful to have a small amount of information on the Floer homology of $\Sigma \times S^1$ with “universal” coefficients, ie, coefficients in the group ring $R_{\Sigma \times S^1}$. Strictly, the material in this section is not necessary for the fiber sum theorems to follow, but we find it conceptually helpful to understand the Floer groups in which relative invariants take values. The result we need, Theorem 9.12 below, states that the Floer homology $HF^+(\Sigma \times S^1, s_{\pm(g-1)}; R_{\Sigma \times S^1})$ is a free module of rank 1, ie, it is isomorphic to...
This statement is in fact a consequence of work of Ozsváth and Szabó [14], who show essentially that if $Y$ is a 3–manifold that fibers over the circle with fiber genus $> 1$, then there is an admissible Heegaard diagram for $Y$ containing just a single generator corresponding to the “extremal” spin$^c$ structure. We give a different argument here based on knot Floer homology in the universally twisted case, which is useful in other situations (eg [6]).

Continuing our notation from the last section, let $Y$ be the manifold $Y = \#^2g(S^1 \times S^2)$. An easy application of Theorem 9.1 (for surgery on the unknot in $S^3$ and with $n = 1$) and the connected sum formula for $\text{HF}^+$ and $\overline{\text{HF}}$ (cf [11]) yields

$$\overline{\text{HF}}(\#^2g(S^1 \times S^2), s_0; R_Y) \cong \mathbb{Z}_{(-g)} \quad \text{and} \quad \text{HF}^+(\#^2g(S^1 \times S^2), s_0; R_Y) \cong T_{-g}$$

where $T_n = \mathbb{Z}[U, U^{-1}]/U \cdot \mathbb{Z}[U]$ as before, graded such that the summand of lowest degree lies in degree $n$. For all spin$^c$–structures $s \neq s_0$, $\text{HF}^+(\#^2g(S^1 \times S^2), s; R_Y)$ and $\overline{\text{HF}}(\#^2g(S^1 \times S^2), s; R_Y)$ are zero, so we shall drop the spin$^c$–structure from our notation. Also, we shall drop the 3–manifold from our notation for the knot Floer homology groups whenever there is not risk of confusion.

**Lemma 9.9** Let $g \geq 1$, set $Y = \#^2g(S^1 \times S^2)$ and let $K_g$ be the nullhomologous knot $K_g = \#^g B(0, 0) \subset Y$. Then for $j \in \{-g, \ldots, g\}$, the twisted knot Floer homology $\overline{\text{HF}}K(K_g, j, s; R_Y)$ is a free module over $R_Y$ having rank $(\frac{2g}{g+j})$ and supported in degree $j$, and is zero for all other values of $j$.

The proof of this lemma relies on a filtered version of Theorem 9.1.

**Theorem 9.10** (Ozsváth–Szabó [10]) Let $K, L \subset \mathbb{Z}$ be two nullhomologous knots with linking number 0. Let $K_0, K_1$ and $K_{-1}$ be the knots in $Z_0(L)$, $Z_1(L)$ and $Z_{-1}(L)$ induced by $K$ where $Z_{\ell}(L)$ is the result of $\ell$–framed surgery on $L$. Then for any $s \in \text{Spin}^c(\mathbb{Z})$ and any $R_Z$–module $M$ there are exact sequences of $R_{Z_0(L)}$–modules: for each $j \in \mathbb{Z}$.

$$\cdots \to \overline{\text{HF}}K(K, s, j; M)[t^{\pm 1}] \to \overline{\text{HF}}K(K_0, [s_k], j; M)[t^{\pm 1}] \to \overline{\text{HF}}K(K_1, [s_k], j; M)[t^{\pm 1}] \to \cdots$$

$$\cdots \to \overline{\text{HF}}K(K, s, j; M)[t^{\pm 1}] \to \overline{\text{HF}}K(K_{-1}, [s_k], j; M)[t^{\pm 1}] \to \overline{\text{HF}}K(K_0, [s_k], j; M)[t^{\pm 1}] \to \cdots \quad \square$$

**Proof of Lemma 9.9** Lemma 9.9 follows from repeated applications of Theorem 9.10 to various triples of knots; our proof is a straightforward adaptation of the $\mathbb{Z}$–coefficient proof first obtained by Ozsváth and Szabó in [10]. We first consider the case of $g = 1$. 

*Geometry & Topology, Volume 12 (2008)*
The three knots \( B(\infty, 1) \to B(0, 1) \to B(1, 1) \) fit into the positive \( n \) surgery sequence from Theorem 9.10. It is easy to see that \( B(\infty, 1) \) is the unknot in \( S^3 \) while \( B(1, 1) \) is the right-handed trefoil. Thus

\[
\widehat{HFK}(B(\infty, 1), j) \cong \begin{cases} \mathbb{Z}(0) & (j = 0) \\ 0 & (j \neq 0) \end{cases}
\]

and

\[
\widehat{HFK}(B(1, 1), j) \cong \begin{cases} \mathbb{Z}(0) & (j = 1) \\ \mathbb{Z}(-1) & (j = 0) \\ \mathbb{Z}(-2) & (j = -1) \\ 0 & (j \neq 0, \pm 1) \end{cases}
\]

where a subscript \((n)\) indicates that the corresponding module is supported in degree \(n\).

Using these in the surgery sequence leads to

\[
\widehat{HFK}(B(0, 1), j; R_{S^1 \times S^2}) \cong \begin{cases} (R_{S^1 \times S^2}(\frac{1}{2})) & (j = 1) \\ (R_{S^1 \times S^2}(\frac{1}{2})) & (j = 0) \\ (R_{S^1 \times S^2}(-\frac{1}{2})) & (j = -1) \\ 0 & (j \neq 0, \pm 1) \end{cases}
\]

In a similar vein using the negative \( n \) surgery sequence from Theorem 9.10 for the triple \( B(\infty, -1) \to B(-1, -1) \to B(0, -1) \) (and observing that \( B(-1, -1) \) is the left-handed trefoil) leads to

\[
\widehat{HFK}(B(0, -1), j; R_{S^1 \times S^2}) \cong \begin{cases} (R_{S^1 \times S^2}(\frac{1}{2})) & (j = 1) \\ (R_{S^1 \times S^2}(\frac{1}{2})) & (j = 0) \\ (R_{S^1 \times S^2}(-\frac{1}{2})) & (j = -1) \\ 0 & (j \neq 0, \pm 1) \end{cases}
\]

For our next set of surgery sequences note that \( B(0, \infty) \) is the unknot in \( S^1 \times S^2 \) and therefore

\[
\widehat{HFK}(B(0, \infty), j; R_{S^1 \times S^2}) \cong \begin{cases} \mathbb{Z}(-\frac{1}{2}) & (j = 0) \\ 0 & (j \neq 0) \end{cases}
\]

where \( \mathbb{Z} \) is the trivial \( R_{S^1 \times S^2} \)-module. Using the negative \( n \) surgery sequence on the triple \( B(0, \infty) \to B(0, -1) \to B(0, 0) \) for \( j = 0 \) shows that

\[
\widehat{HFK}(-1)(B(0, 0), 0; R_{\#^2(S^1 \times S^2)}) = 0.
\]

The positive \( n \) surgery sequence for the triple \( B(0, \infty) \to B(0, 0) \to B(0, 1) \) for \( j = \pm 1 \) leads to

\[
\widehat{HFK}(B(0, 0), j; R_{\#^2(S^1 \times S^2)}) \cong (R_{\#^2(S^1 \times S^2)}(j)) \quad (j = \pm 1)
\]
Product formulae for Ozsváth–Szabó 4–manifold invariants

The results of Lemma 9.9 can be rewritten in a more concise way as follows: let \( R \) be the free \( R \)-module of rank \( 2g \) (with \( R \) still denoting \( R = \mathbb{Z}[S^1 \times S^2] \)). Then for \( j = -g, \ldots, g \) we have \( HF^g(K_g, j; R) \cong \Lambda^g \otimes M \) supported entirely in grading \( j \).

Recall that there is a spectral sequence associated to the knot filtration, whose \( E^1 \) term is \( HF^g(K_g, j; R) \), and whose \( E^\infty \) term is \( HF^g(S^1 \times S^2; R) \cong \mathbb{Z}(-g) \).
Since the grading of any term in $\widehat{HFK}(K_g, j; R)$ equals $j$, it follows that this spectral sequence collapses at the $E^2$ stage, in particular the only nonzero differentials in the spectral sequence are those on the $E^1$ level:

$$\partial_v: \Lambda^{\ell+1}M \rightarrow \Lambda^\ell M \quad \ell = 0, \ldots, 2g - 1.$$ 

In particular, we infer that the chain complex

$$0 \rightarrow \Lambda^{2g}M \xrightarrow{\partial_v} \Lambda^{2g-1}M \xrightarrow{\partial_v} \cdots \xrightarrow{\partial_v} \Lambda^1 M \xrightarrow{\partial_v} \Lambda^0 M \rightarrow 0$$

which appears at the $E^1$ stage of the spectral sequence has homology equal to $\overline{HF}(\#^{2g}S^1 \times S^2; R) = \mathbb{Z}_{(-g)}$. In other words, the complex above is a (minimal) free resolution of $\mathbb{Z}$ in the category of $R$–modules, which we will be a useful observation for us momentarily.

As before, knowledge of the knot Floer homology of $K_g$ allows calculation of the Floer homology of large integer surgeries along $K_g$. We will need only the following result; the twisted Floer homology of circle bundles is studied in greater depth in [6].

**Lemma 9.11** Fix $g \geq 2$ and $n \gg 0$. There is an isomorphism of $R_Y \otimes \mathbb{Z}[U]$–modules

$$HF^+(Y_n, s_{\pm(g-1)}; R_Y) \cong R_Y \oplus T_{-g-\tau},$$

where $\tau = (n - (2g - 2 - n)^2)/(4n)$, and $R_Y$ is supported in degree $g - 2 - \tau$ (with trivial action by $U$).

Observe that there is an identification $H^1(Y_n; \mathbb{Z}) = H^1(Y; \mathbb{Z})$, so that $R_Y = R_Y$.

**Proof** By conjugation symmetry, we may consider only the case of $s_{g-1}$. We have

$$HF^+(Y_n, s_{g-1}; R_Y) \cong H\{i \geq 0 \text{ or } j \geq g - 1\}.$$ 

To calculate this homology, we use the filtration induced by $i + j$ as before to obtain a spectral sequence with $E^1$ term $\overline{HF}(\#^{2g} B(0,0), R_Y) \otimes \mathbb{Z}[U, U^{-1}]$ (or, the portion of this group lying in the region $\{i \geq 0 \text{ or } j \geq g - 1\}$). From the work above, we can express this as $E^1_{i,j} = \Lambda^{g+j-i}M \otimes U^{-i}$, and for dimensional reasons only the $d_1$ differential can be nontrivial in the spectral sequence. Since $d_1$ splits as horizontal and vertical parts as before, we can consider $E^1$ as a double complex and use a second spectral sequence to calculate its homology. Specifically: we use the spectral sequence that arises from the filtration of $E^1$ by the subcomplexes $\{i \leq i_0\}$.

The first stage in this secondary spectral sequence calculates the homology of the vertical differential. In each column $i = c$ with $c \geq 0$, we see a shifted copy of the complex (31) above, thus the homology of such a column is $\mathbb{Z}$ supported in degree...
The only other nonzero column is \( i = -1 \), which contains the single term \( \Lambda^{2g} M \cong R_Y \) in degree \( g - 2 \) (and hence is equal to its homology). Further differentials in the secondary spectral sequence must be trivial: the only possible differential would map \( \mathbb{Z} \) into \( \Lambda^{2g} M \), but there are no nontrivial \( R_Y \)-module maps of the torsion module \( \mathbb{Z} \) into the free module \( \Lambda^{2g} M \). Hence the lemma follows, recalling that the identification of \( HF^+(Y_n, s_{g-1}) \) with \( H\{ i \geq 0 \text{ or } j \geq g-1 \} \) shifts degree by \( \tau \).

\[ \text{Theorem 9.12} \quad \text{Let } g \geq 2. \text{ The Floer homology of } Y_0 = \Sigma_g \times S^1 \text{ in the spin}^c \text{ structure } t_{\pm(g-1)} \text{ characterized by } c_1(t_{\pm(g-1)}) = \pm (2g - 2) \text{ PD}[S^1] \text{ is given as an } R_{Y_0} \text{-module by} \]

\[ HF^+(Y_0, t_{\pm(g-1)}; R_{Y_0}) \cong R_{Y_0}, \]

with trivial action by \( U \).

\[ \text{Proof} \quad \text{As usual, we consider } t_{g-1} \text{ only. We consider the surgery sequence for large positive surgeries, which gives rise to an exact triangle:} \]

\[
\begin{array}{ccc}
HF^+(Y_n, s_{g-1}, R_Y)[t] & \xrightarrow{F} & HF^+(Y, s, R_Y)[t] \\
& & \\
& & HF^+(Y_0, t_{g-1}, R_{Y_0})
\end{array}
\]

Here we have chosen \( n \) large enough that \( t_{g-1} \) is the only spin\(^c \) structure in the equivalence class \([s_{g-1}]\) having nontrivial Floer homology, and of course \( s \) is the torsion spin\(^c \) structure on \( Y = #^{2g} S^1 \times S^2 \).

The highest-degree component of \( F \) is the \( t \)-linear extension of the natural projection \( H\{ i \geq 0 \text{ or } j \geq g-1 \} \rightarrow H\{ i \geq 0 \} \), which is an isomorphism in all degrees \( d \geq g - 1 - \tau \), with \( \tau \) as in the preceding lemma. It follows that \( F \) itself is an isomorphism in those degrees. By \( U \)-equivariance, we have that \( F \) restricts to the factor \( T_{g-\tau} \subset HF^+(Y_n, s_{g-1}; R_Y) \) as an isomorphism onto \( T_{g} = HF^+(Y, s; R_Y) \), whence \( HF^+(Y_0, t_{g-1}; R_{Y_0}) \cong \ker(F) \). We claim that \( \ker(F) \cong R_Y[t^{\pm 1}] \cong R_{Y_0} \).

To see this it suffices to find the kernel of \( F \) restricted to some bounded range of degrees, where we know \( F \) can be identified with \( F_0 + tF_1 \) (continuing notation from previously). Furthermore, results of Ozsváth and Szabó [16] show that \( F_1 \) is identified (up to chain isomorphism) with the projection

\[ H\{ i \geq 0 \text{ or } j \geq g-1 \} \rightarrow H\{ j \geq g-1 \}. \]
and in particular is surjective in all high degrees. Then $U$–equivariance of maps induced by cobordisms implies $F_1$ (and also $F_0$) must vanish on $HF^+_{\text{red}}(Y_\eta, s_{g-1}, R_Y)[t^\pm 1] = R_Y[t^\pm 1]$, since $Y$ has no reduced Floer homology.

\section{Product formulae}

We can now piece together the ingredients of the preceding sections to deduce the results stated in the introduction. The conceptual plan is reasonably straightforward: if $X = M_1 \#_\Sigma M_2$ is a fiber sum as in the introduction, then the Ozsváth–Szabó invariants for $X$ are given by a pairing between relative invariants for $Z_i = M_i \setminus (\Sigma \times D^2)$, after perturbing by a class $\eta \in H^2(X; \mathbb{R})$ that restricts nontrivially to $\Sigma \times S^1$, according to Theorem 8.17.

To determine the relative invariants $\Psi_{Z_i, \eta}$ of the pieces and obtain a formula for $\text{OS}_X$ in terms of $\text{OS}_{M_i}$, we observe that the Ozsváth–Szabó invariants of the $M_i$ are themselves determined by the pairing between $\Psi_{Z_i, \eta}$ and the relative invariant of $\Sigma \times D^2$, again using the perturbed version of Floer theory since, even if $b^+(\Sigma) > 0$, we have $b^+(\Sigma \times D^2) = 0$ and Theorem 7.6 need not apply. Hence we need to understand the perturbed relative invariant $\Psi_{\Sigma \times D^2, \eta}$, as well as the relevant pairing on Floer homology.

Now, it is easy to see that the coefficient module for $\Sigma \times S^1$ induced by $\Sigma \times D^2$ (with a 4–ball removed) is $\mathbb{Z}[K(\Sigma \times D^2)] = L(t)$, where $t \in H^1(\Sigma \times S^1; \mathbb{Z})$ is a generator Poincaré dual to $\Sigma \times \text{pt}$. There is little choice in the perturbation $\eta$ on $\Sigma \times D^2$; namely we take $\eta$ to be (a positive multiple of the) Poincaré dual to the relative class $\text{pt} \times D^2$, which has $(t \cup \eta, [\Sigma \times S^1]) = 1$. Thus the Novikov completion of $L(t)$ with respect to $\eta$ is the ring $\mathcal{L}(t)$ of Laurent series in $t$.

Assuming $[\Sigma]$ to be (rationally) nontrivial in $M_1$ and $M_2$, we can extend $\eta$ to $M_i$, and consider the relative invariants of the complements $Z_i$. In particular, if $\mathcal{K}(Z_i, \eta)$ is the module for $\mathcal{R}_{\Sigma \times S^1, \eta}$ induced by $(Z_i, \eta)$, we are interested in the pairing

$$HF^-_{\Sigma \times S^1, \eta} \otimes HF^+_{\Sigma \times S^1, \eta} \to \mathcal{K}(M_i, \Sigma \times S^1, \eta)$$

$$\xi_1 \otimes \xi_2 \mapsto \langle \tau^{-1}(\xi_1), \xi_2 \rangle$$

between the perturbed Floer homologies. In fact, more specifically we are interested in the homomorphism $HF^-_{\Sigma \times S^1, \eta} \to \mathcal{K}(M_i, \Sigma \times S^1, \eta)$ induced by the pairing above when $\xi_2$ is equal to $\Psi_{\Sigma \times D^2, \eta}$, the relative invariant for $\Sigma \times D^2$.

Now, it is a simple exercise to see that $\mathcal{K}(M_i, \Sigma \times S^1)$ is cyclic, generated by the Poincaré dual of $[\Sigma]$ in $H^2(M_i)$. Since $\Sigma$ is assumed to represent a nontorsion class
in each of $M_1$ and $M_2$, then, we have $\mathcal{K}(M_i; \Sigma \times S^1, \eta) \cong \mathcal{L}(t)$. There is a natural surjection

$$\rho: K(Z_i) \cong \frac{H^1(\Sigma \times S^1)}{H^1(Z_i)} \rightarrow \frac{H^1(\Sigma \times S^1)}{H^1(Z_i) + H^1(\Sigma \times D^2)} \cong K(M_i; \Sigma \times S^1),$$

inducing a surjection $\rho: K(Z_i; \eta) \rightarrow \mathcal{L}(t)$ (cf Lemma 8.2), and a commutative diagram

$$
\begin{array}{ccc}
HF_*^-(\Sigma \times S^1; K(Z_i; \eta)) & \xrightarrow{\{\tau^{-1}(\cdot), \Psi_{\Sigma \times D^2, \eta}\}} & K(M_i; \Sigma \times S^1, \eta) \cong \mathcal{L}(t) \\
\rho_* & \downarrow & \\
HF_*^-(\Sigma \times S^1; \mathcal{L}(t)) & \xrightarrow{\{\tau^{-1}(\cdot), \Psi_{\Sigma \times D^2, \eta}\}} & \mathcal{L}(t)
\end{array}
$$

(cf Lemma 7.7 and Lemma 7.8). We will see that the arrow on the bottom of this diagram is determined essentially uniquely by algebraic considerations. Hence, determining the pairing mentioned above is equivalent to understanding the change-of-coefficient map $\rho_*$, and the relative invariant $\Psi_{\Sigma \times D^2, \eta}$.

Naturally, we cannot hope to do better than determining these objects up to a unit in $\mathcal{L}(t)$. Since units abound in a power series ring, this is not necessarily sufficient. However, we know that all the algebra we must use in the context of Novikov rings is induced from corresponding algebra over ordinary group rings: that is, the perturbed case is an obvious Novikov completion of the unperturbed case. Since $L(t)$ has many fewer units than $\mathcal{L}(t)$, this is a useful observation: we work initially in twisted, but unperturbed, coefficients.

### 10.1 Relative invariants in case $g = 1$

Let $M$ be a closed 4–manifold with $b^+(M) \geq 1$ containing a smoothly embedded torus $T \hookrightarrow M$ with trivial normal bundle. We assume that $[T]$ is an element of infinite order in $H_2(M)$. Write $T \times D^2$ for a tubular neighborhood of $T$, and let $Z = M \setminus (T \times D^2)$ be the complement of this neighborhood. We wish to understand the relationship between the Ozsváth–Szabó invariants of $M$ and the relative invariant of $Z$. If $b^+(M) = 1$, we will be interested in the invariant $\Phi_{M, T \times S^1, \eta}$, where $\eta \in H^2(M; \mathbb{R})$ is a class that restricts to $T \times D^2$ as a nonzero multiple of the Poincaré dual of the relative class $[pt \times D^2]$. 

*Geometry & Topology, Volume 12 (2008)*
Recall the following result of Ozsváth and Szabó.

**Theorem 10.1 (Ozsváth–Szabó [9, Proposition 8.5])** The twisted Heegaard Floer homology \( HF^+(T^3, s; R_{T^3}) \) is trivial unless \( s \) is equal to the unique spin\(^c \) structure \( s_0 \) with \( c_1(s_0) = 0 \). In this case, there is an isomorphism

\[
HF^+(T^3, s_0; R_{T^3}) = T_{1/2} \oplus \ker(\varepsilon),
\]

where \( T_{1/2} \) is the \( \mathbb{Z}[U] \)-module \( \mathbb{Z}[U, U^{-1}] / \mathbb{Z}[U] \), graded so that its homogeneous summand of least degree lies in dimension 1/2, and

\[
\varepsilon: R_{T^3} = \mathbb{Z}[H^1(T^3)] \to \mathbb{Z}
\]
is the augmentation homomorphism that maps each element of \( H^1(T^3) \) to 1. In the above, \( \ker(\varepsilon) \) lies in degree \(-1/2\).

In particular, the reduced Floer homology \( HF^\text{red}_i(T^3, s_0; R_{T^3}) \) in the fully-twisted case is equal to \( \ker(\varepsilon) \), lying entirely in degree \(-1/2\).

**Proposition 10.2** Let \( Z = M \setminus (T \times D^2) \) be the complement of an essentially embedded torus in a 4–manifold as above, and let \( K(Z) = \ker(H^2(\partial Z, \partial Z) \to H^2(Z)) \) as usual, so that \( K(Z) \cong H^1(T^3)/H^1(Z) \). Then \( HF^+_k(T^3, s_0; \mathbb{Z}[K(Z)]) = 0 \) if \( k < -1/2 \), and there is an isomorphism

\[
HF^+_{-1/2}(T^3, s_0; \mathbb{Z}[K(Z)]) \cong \ker(\varepsilon) \otimes_{R_{T^3}} \mathbb{Z}[K(Z)].
\]

The change-of-coefficient map \( \rho_*: HF^+(T^3, s_0; \mathbb{Z}[K(Z)]) \to HF^+(T^3, s_0; L(t)) \) is given by the natural map

\[
\text{id} \otimes \rho: \ker(\varepsilon) \otimes_{R_{T^3}} \mathbb{Z}[K(Z)] \to \ker(\varepsilon) \otimes_{R_{T^3}} L(t)
\]

**Proof** For an \( R_{T^3} \)-module \( M \), there is a “first quadrant” universal coefficients spectral sequence converging to \( HF^+(T^3, s_0; M) \), which has \( E_2 \) term equal to \( \text{Tor}^i(HF^+_i(T^3; R_{T^3}), M) \). In particular, the group in lowest total degree in the \( E_2 \) term is

\[
\text{Tor}^0(HF^+_{-1/2}(T^3; R_{T^3}), M) = HF^+_{-1/2}(T^3; R_{T^3}) \otimes M = \ker(\varepsilon) \otimes M.
\]

From the structure of the differentials in the spectral sequence this group must survive as the lowest-degree part of \( E_\infty \), which proves the first statement.

If \( \rho: M \to M' \) is a module homomorphism then we get a corresponding map of spectral sequences, for which the map on the \( E_2 \) term is \( \text{id} \otimes \rho \) on the \( j = 0 \) row. The second statement of the theorem follows as before, since we consider only the bottom-degree groups. \( \square \)
Note that although the fully-twisted Floer homology for $T^3$ in dimension $-1/2$ is precisely equal to the reduced Floer homology, the same is not true in other coefficient systems (indeed, with untwisted coefficients, the reduced Floer homology is trivial). For example, in Section 9.1 we found that there is an isomorphism

$$HF^{+}_{-1/2}(T^3, s_0; L(t)) = \ker(\varepsilon) \otimes L(t) = \mathbb{Z} \oplus \mathbb{Z} \oplus L(t),$$

and in this decomposition only the $L(t)$ factor lies in the reduced Floer homology. However, there is a natural projection $HF^+ \to HF^+_\text{red}$ for any 3–manifold and any coefficient module. When we apply $\rho_*$ we often implicitly compose with this projection without including it in the notation, and hope this will not cause confusion; note that this problem disappears when we pass to perturbed Floer homology.

In the special case $K(Z) = H^1(T^3)$ (equivalently, the restriction $H^1(Z) \to H^1(T^3)$ is trivial), we can identify the change-of-coefficient map (in reduced Floer homology) with the surjection

$$H: \ker(\varepsilon) \to L(t)$$

$$a(r, s, t) \mapsto \frac{a(1, 1, t)}{t - 1}.$$

Indeed, thinking of $\mathbb{Z}[K(Z)] = R_{T^3}$ as the ring of Laurent polynomials in three variables $r, s, t$, we have that $\ker(\varepsilon)$ is the ideal generated by the three elements $r - 1$, $s - 1$, and $t - 1$. In particular, if $a(r, s, t) \in \ker(\varepsilon)$, then $a(1, 1, t)$ is divisible by $t - 1$; the given map is uniquely determined up to units in $R_{T^3}$.

With this understanding of the change of coefficients in the unperturbed case, we can now introduce a perturbation $\eta$. As before, we choose any $\eta \in H^2(M; \mathbb{R})$ such that the restriction of $\eta$ to $T^2 \times D^2$ is Poincaré dual to $pt \times D^2$. To understand the relative invariant $\Psi_{T^2 \times D^2, \eta}$, observe first that $HF^+(T^3, s; M)$ is trivial for any $\mathcal{R}_{T^3}$–module $\mathcal{M}$ unless $s = s_0$, the unique spin$^c$ structure with $c_1(s_0) = 0$. Thus from now on we consider only spin$^c$ structures on $M$ that restrict to $s_0$ on $T^3$, which means also that $c_1(s)|_{T^2 \times D^2} = 0$. It is straightforward to see that in the fully-twisted case, $HF^+(T^3, s_0; \mathcal{R}_{T^3, \eta}) \cong \mathcal{R}_{T^3, \eta}$, using Lemma 8.4 and Theorem 10.1.

Consider the complement $Z = M \setminus (T^2 \times D^2)$ as a cobordism $S^3 \to T^3$ by removing a 4–ball (we still use the symbol $Z$ for this cobordism). In this situation the diagram

\[\text{Diagram}\]
(17) becomes

\[
\begin{array}{c}
HF^{-}(S^{3}) \xrightarrow{F_{Z}} HF^{-}(T^{3}; \mathbb{Z}[K(Z)]) \\
\downarrow i_{*} \\
HF_{*}^{-}(T^{3}; K(Z, \eta)),
\end{array}
\]

where \(i_{*}\) is the homomorphism induced by the natural map \(i: \mathbb{Z}[K(Z)] \to K(Z, \eta)\).

If \(K(Z) = H^{1}(T^{3})\) (e.g., if the complement of \(T\) in \(M\) is simply connected), then in the lowest nontrivial degree, \(i_{*}\) is a map \(\ker(\varepsilon) \to \mathcal{R}_{T^{3}}\). This is induced by the natural homomorphisms

\[
HF^{-}(T^{3}; R_{T^{3}}) \to HF^{-}(T^{3}; R_{T^{3}}) \otimes \mathcal{R}_{T^{3}, \eta}
\]

\[
\to HF^{-}(T^{3}; R_{T^{3}} \otimes \mathcal{R}_{T^{3}, \eta}) \to HF_{*}^{-}(T^{3}; \mathcal{R}_{T^{3}, \eta})
\]

\[
[x] \longrightarrow [x] \otimes 1 \longrightarrow [x \otimes 1]
\]

so we can think of \(i_{*}\) as the homomorphism mapping a Laurent polynomial \(a(r, s, t) \in \ker(\varepsilon)\) into the Laurent series ring \(\mathcal{R}_{T^{3}, \eta}\) by the natural inclusion.

Continuing to assume that \(K(Z) = H^{1}(T^{3})\), we consider the diagram

\[
\begin{array}{c}
HF^{-}_{-1/2}(T^{3}; R_{T^{3}}) \xrightarrow{i_{*}} L(t) \\

\downarrow \rho_{*}

HF^{+}_{-1/2}(T^{3}; \mathcal{R}_{T^{3}, \eta}) \xrightarrow{\langle a, F_{T^{2} \times D^{2}}^{-}(\Theta^{-}) \rangle} \mathcal{L}(t)
\end{array}
\]

(34)

where the upper arrow is \(a \mapsto \langle a, F_{T^{2} \times D^{2}}^{-}(\Theta^{-}) \rangle\), and the middle arrow is \(b \mapsto \langle b, \Psi_{T^{2} \times D^{2}, \eta} \rangle\). In the unperturbed case, we have

\[
\langle a, F_{T^{2} \times D^{2}}^{-}(\Theta^{-}) \rangle = \langle \rho_{*}(a), F_{T^{2} \times D^{2}}^{-}(\Theta^{-}) \rangle = \langle F_{T^{2} \times D^{2}}^{+}(\rho_{*}(a)), \Theta^{-} \rangle
\]

where \(\rho_{*}\) is the projection to \(L(t)\) coefficients. We know that in \(L(t)\) coefficients, \(F_{T^{2} \times D^{2}}^{+}\) induces a surjection to \(L(t)\) (see the discussion at the end of Section 9.1).
It follows from (the unperturbed analog of) (33) and Proposition 10.2 that the upper arrow in (34) is given by

\[ a \mapsto \langle a, F_{T^2 \times D^2}^-(\Theta^-) \rangle = H(a), \]

where \( H: \ker(\epsilon) \to L(t) \) is the homomorphism introduced above.

On the other hand, if we think of \( a \in \ker(\epsilon) \) as a Laurent polynomial \( a(r, s, t) \) then \( i_*(a) = a \). The coefficient-change map \( \rho_*: HF^+(T^3; \mathcal{R}_{T^3, \eta}) \cong \mathcal{R}_{T^3, \eta} \to HF^+(T^3; \mathcal{L}(t)) \cong \mathcal{L}(t) \) is necessarily the reduction \( b(r, s, t) \mapsto b(1, 1, t) \), so that \( \rho_*(i_*(a)) = a(1, 1, t) \).

Thus, \( \Psi_{T^2 \times D^2, \eta}(1) \) is a generator of \( HF^{-1/2}(T^3; \mathcal{L}(t)) \), satisfying the property that for \( a(r, s, t) \in \ker(\epsilon) \),

\[ \langle a, \Psi_{T^2 \times D^2, \eta}(1) \rangle = H(a) = \frac{a(1, 1, t)}{t-1}, \]

up to a unit in \( L(t) \). Identifying \( HF_{-1/2}(T^3; \mathcal{L}(t)) = \mathcal{L}(t) \), the diagonal arrow in the preceding diagram can be taken to be multiplication by \( \Psi_{T^2 \times D^2, \eta}(1) \). We conclude:

**Proposition 10.3** The relative invariant \( \Psi_{T^2 \times D^2, \eta} \) can be identified with the map \( \Lambda(T^2 \times D^2) \to HF^-(T^3, s_0; \mathcal{L}(t)) \cong \mathcal{L}(t) \) whose value on the element 1 is

\[ \Psi_{T^2 \times D^2, \eta}(1) = \frac{1}{t-1} \]

up to multiplication by \( \pm t^n \), and which vanishes on elements of \( \Lambda(T^2 \times D^2) \) having nonzero degree.

Let \( M \) be a closed 4–manifold containing an embedded torus \( T \) with trivial normal bundle, and \( \eta \in H^2(M; \mathbb{R}) \) a class with \( \int_T \eta > 0 \). Let \( s \) be a spin\(^c\) structure on \( M \), and write \( Z = M \setminus (T \times D^2) \). If \( \langle c_1(s), [T] \rangle \neq 0 \), then the relative invariant \( \Psi_{Z, \eta, s} \) and the closed invariant \( \Phi_{M, T^3, S^1, \eta, s} \) both vanish.

If \( \langle c_1(s), [T] \rangle = 0 \), then the relative invariant \( \Psi_{Z, \eta, s} \) takes values in the Novikov ring \( \mathcal{K}(Z, \eta) \). Furthermore, the value of the perturbed Ozsváth–Szabó invariant on a class \( \alpha_1 \otimes \alpha_2 \) with \( \alpha_1 \in \Lambda(Z), \alpha_2 \in \Lambda(T^2 \times D^2) \), is given up to multiplication by \( \pm t^n \) by

\[ \Phi_{M, T^3, \eta, s}(\alpha_1 \otimes \alpha_2) = \langle \tau^{-1} \Psi_{Z, \eta, s}(\alpha_1), \Psi_{T^2 \times D^2, \eta, s}(\alpha_2) \rangle \]

\[ = \begin{cases} 
\frac{1}{t-1} \rho(\Psi_{Z, \eta, s}(\alpha_1)) & \text{if } \alpha_2 = 1 \\
0 & \text{otherwise},
\end{cases} \]

where \( \rho \) is the natural map \( \mathcal{K}(Z, \eta) \to \mathcal{L}(t) \) induced by the projection \( \mathcal{K}(Z) \to K(M, T^3) \cong \mathbb{Z} \).

*Geometry & Topology, Volume 12 (2008)*
Note that since $\eta$ is defined on all of $M$, the fact that the induced homomorphism $\rho$ is well-defined follows from Lemma 8.2.

Proof First, observe that since the Floer homology $HF^-(T^3, s_0; \mathcal{M})$ is supported entirely in degree $-1/2$ for any $\mathcal{R}_{T^3, \eta}$-module $\mathcal{M}$, the elements of $\mathbb{A}(T^2 \times D^2)$ having nonzero degree must act trivially. Thus, only $\Psi_{T^2 \times D^2, \eta}(1)$ can be nontrivial.

If $H^1(Z) \to H^1(T^3)$ is trivial, then $\mathcal{K}(Z, \eta) = \mathcal{R}_{T^3, \eta}$ and the result follows from the preceding discussion. In the general case, observe that since $HF^-(T^3, s_0; \mathcal{R}_{T^3, \eta}) \cong \mathcal{R}_{T^3, \eta}$ is free over $\mathcal{R}_{T^3, \eta}$, we have

$$HF^-(T^3, s_0; \mathcal{K}(Z, \eta)) \cong \mathcal{R}_{T^3, \eta} \otimes \mathcal{R}_{T^3, \eta} \mathcal{K}(Z, \eta) = \mathcal{K}(Z, \eta).$$

Thus the last statement of the proposition follows from (35) and (34).

10.2 Relative invariants in case $g > 1$

We follow an outline similar to the previous subsection; as before, we begin with twisted but unperturbed coefficients.

Let $\Sigma \hookrightarrow M$ be an embedded surface of square 0 and genus $g$ and $s \in \text{Spin}^c(M)$ a spin$^c$ structure. We have seen that unless $c_1(s)|_{\Sigma \times S^1}$ is Poincaré dual to $2k[pt \times S^1]$ with $|k| \leq g - 1$, the Floer homology $HF^+(\Sigma \times S^1, s; N) = 0$ for any $R_{\Sigma \times S^1}$-module $N$ (and similarly after perturbation), forcing $\Phi_{M, \Sigma \times S^1, \eta, s} = 0$ for such $s$. Thus we suppose that the restriction of $s$ has the indicated form; we write $s_k$ for the spin$^c$ structure on $\Sigma \times S^1$ with $c_1(s_k) = 2k \text{ PD}[S^1]$.

The following is an easy consequence of Theorem 9.12, together with the universal coefficients spectral sequence.

Lemma 10.4 Let $N$ be a module for $R_{\Sigma \times S^1}$. Then when $|k| = g - 1$, we have an isomorphism

$$HF^\text{red}_-(\Sigma \times S^1, s_k; N) = HF^+(\Sigma \times S^1, s_k; N) = N.$$

If $Z = M \setminus (\Sigma \times D^2)$ is the complement of a surface representing a class of infinite order in $H_2(M; \mathbb{Z})$, then the homomorphism

$$\rho_* : HF^+_\text{red}(\Sigma \times S^1, s_k; \mathbb{Z}[K(Z)]) \to HF^+_\text{red}(\Sigma \times S^1, s_k; L(t))$$

is equal to the projection $\rho : \mathbb{Z}[K(Z)] \to \mathbb{Z}[K(M, \Sigma \times S^1)] = L(t)$. 

Applying a perturbation $\eta \in H^2(M; \mathbb{R})$ restricting as a positive multiple of the Poincaré dual of $[pt \times D^2]$ on $\Sigma \times D^2$ as before, we obtain the following, which describes the relative invariant of $\Sigma \times D^2$ for general $k$, and gives the analog of Proposition 10.3 in higher genus for $|k| = g - 1$.

**Proposition 10.5** For the spin$^c$ structure $s_k$ on $\Sigma \times D^2$ with $c_1(s_k)$ Poincaré dual to $2k[pt \times D^2]$, the relative invariant $\Psi_{\Sigma \times D^2, n, s_k}$ is a linear map

$$\Lambda(\Sigma \times D^2) \to HF^*_-(\Sigma \times S^1, s_k; \mathcal{L}(t))$$

whose value $\Psi_{\Sigma \times D^2, n, s_k}(1)$ lies in the summand of maximal height (cf Remark 9.7). Furthermore, there is a natural identification $HF^*_{\text{top}}(\Sigma \times S^1, s_k; \mathcal{L}(t)) \cong \mathcal{L}(t)$ such that

$$\Psi_{\Sigma \times D^2, n, s_k}(1) = 1$$

up to multiplication by $\pm t^n$. More generally, if $\alpha \in \Lambda(\Sigma \times D^2)$ then $\Psi_{\Sigma \times D^2, n, s_k}(\alpha) = \alpha.1$, where the right hand side makes use of the action of $\Lambda^*H_1(\Sigma \times S^1; \mathbb{Z}) \otimes \mathbb{Z}[U]$ on $HF^*_-(\Sigma \times S^1, s_k; \mathcal{L}(t))$.

Let $Z: S^3 \to \Sigma \times S^1$ be a cobordism and $\eta \in H^2(Z; \mathbb{R})$ a class restricting to $\Sigma \times S^1$ as a positive multiple of the Poincaré dual of $pt \times S^1$. Let $s$ be a spin$^c$ structure on $Z$ restricting to the spin$^c$ structure $s_k$ on $\Sigma \times S^1$, where $|k| = g - 1$. Then $\Psi_{Z, n, s}$ takes values in the Novikov ring $K(Z, \eta)$.

Finally, let $M$ be the closed manifold obtained by gluing $\Sigma \times D^2$ to $Z$, and filling in the other boundary component of $Z$ by a 4–ball. Extend $\eta$ across $\Sigma \times D^2$ and $B^4$ to give a class $\eta \in H^2(M; \mathbb{R})$. For a spin$^c$ structure $s$ with $c_1(s)[\Sigma \times D^2]$ Poincaré dual to $\pm(2g - 2)[pt \times D^2]$, the value of the perturbed Ozsváth–Szabó invariant $\Phi_{M, \Sigma \times S^1, n, s}$ on $\alpha_1 \otimes \alpha_2 \in \Lambda(Z) \otimes \Lambda(T^2 \times D^2)$ is given by

$$\Phi_{M, \Sigma \times S^1, n, s}(\alpha_1 \otimes \alpha_2) = (\tau^{-1}\Psi_{Z, n, s}(\alpha_1), \Psi_{\Sigma \times D^2, n, s}(\alpha_2))$$

$$= \begin{cases} \rho(\Psi_{Z, n, s}(\alpha_1)) & \text{if } \alpha_2 = 1 \\ 0 & \text{otherwise,} \end{cases}$$

where $\rho$ is the natural map $K(Z, \eta) \to \mathcal{L}(t)$ induced by the projection $K(Z) \to K(M, \Sigma \times S^1) \cong \mathbb{Z}$.

**Proof** We have seen that the homomorphism $F^+_{\Sigma \times D^2, s_k}: HF^+(\Sigma \times D^2, s_k; \mathcal{L}(t)) \to HF^+(S^3; \mathcal{L}(t))$ can be identified with the projection of $X(g, d) \otimes \mathcal{L}(t)$ onto the
We have seen in Theorem 9.4 that there is an isomorphism $HF^+(\Sigma \times S^1, s_k; \mathcal{K}(Z, \eta))$.

\[ \langle x, F^+_{\Sigma \times D^2, \eta, s_k}(\Theta^-) \rangle = \langle F^+_{\Sigma \times D^2, \eta, s_k}(x), \Theta^- \rangle = \begin{cases} \rho(x) & \text{if } \rho(x) \text{ has minimal height} \\ 0 & \text{otherwise} \end{cases} \]

The analog of diagram (34) with $\Sigma \times S^1$ in place of $T^2$ implies that $\Psi_{\Sigma \times D^2, \eta, s_k}(1) = F^+_{\Sigma \times D^2, \eta, s_k}(\Theta^-)$ is a class pairing with $x$ to give $\rho(x)$ when the latter has minimal height, and $0$ otherwise. It is not hard to see that the pairing between $HF^+$ and $HF^-$ can be nontrivial only on elements of complementary height, and we have seen (Theorem 9.4) that the summands in minimal and maximal height in the Floer homology are $HF^+_{\text{bot}}(\Sigma \times S^1, s_k; \mathcal{L}(t)) \cong \mathcal{L}(t)$ and $HF^-_{\text{top}}(\Sigma \times S^1, s_k; \mathcal{L}(t)) \cong \mathcal{L}(t)$. Hence the $\mathcal{L}(t)$–valued pairing between these groups must be given by multiplication of Laurent series (up to a unit in $L(t)$, since the pairing is induced from the unperturbed situation).

The above can therefore be interpreted as the statement that $\Psi_{\Sigma \times D^2, \eta, s_k}(1) = 1$.

Since $A(\Sigma \times S^1) \to A(\Sigma \times D^2)$ is surjective, the statement $\Psi_{\Sigma \times D^2, \eta, s_k}(\alpha) = \alpha.1$ holds by the naturality of cobordism-induced homomorphisms under the action of $H_1$.

The remaining statements follow from the preceding lemma, together with (36). □

The expression of the relative invariant $\Psi_{Z, \eta, s}$ where $c_1(s)|_{\Sigma \times S^1} = PD(2[k \times t\Sigma])$ with $|k| \leq g - 1$ is somewhat more complicated; in principle it may take as a value any element of the Floer homology $HF^+_\bullet(\Sigma \times S^1, s_k; \mathcal{K}(Z, \eta))$, which in the case at hand is not a cyclic module. However, it is still possible to express the relative invariant for $Z$ (after applying $\rho$) in terms of the absolute invariants for $M$. To do so, we make use of the structure of the Floer homology of $\Sigma \times S^1$ deduced previously.

First, recall that the graded group $X(g, d)$ is equipped with a “standard” action of $\Lambda^* H_1(\Sigma) \otimes \mathbb{Z}[U]$. In fact, suppose $B_{g,d} = \{ \beta \} \subset X(g, d)$ is a basis for $X(g, d)$ as a free abelian group, with each $\beta$ a homogeneous element. Then it is easy to see that there is a uniquely determined collection of elements $\{ \tilde{\beta} \} \subset \Lambda^* H_1(\Sigma) \otimes \mathbb{Z}[U]$ (lying in degrees $\leq 2d$) with the property that $\tilde{\beta} \cap \tilde{\beta}' = \delta_{\beta \beta'} \cdot 1$ for $\beta, \beta' \in B_{g,d}$, where $\cap$ is the standard action, $\delta_{\beta \beta'}$ is the Kronecker delta, and $1$ denotes a fixed generator in lowest degree for $X(g, d)$.

We have seen in Theorem 9.4 that there is an isomorphism $HF^+_\bullet(\Sigma \times S^1, s_k; \mathcal{L}(t)) \cong X(g, d) \otimes \mathcal{L}(t)$, and furthermore that the action of $\Lambda^* H_1(\Sigma \times S^1) \otimes \mathbb{Z}[U]$ agrees with the $\mathcal{L}(t)$–linear extension of the standard action to leading order in $t$ (and that the class $pt \times S^1$ acts trivially). Suppose first that $k \neq 0$, so that the variable $t$ carries a nonzero degree. The pairing $\langle \cdot, \cdot \rangle$ between $HF^+_\bullet$ and $HF^-_\bullet$ is nontrivial only on elements of complementary height, and is induced from the untwisted pairing since
in our situation the twisting is trivial. Writing $\Xi$ for the generator in maximal height given by $\Psi_{\Sigma \times D^2, \eta, s_k}(1)$, it follows for dimensional reasons that if the degree of $\tilde{\beta}$ is equal to the height of $x \in X(g, d)$, then
\[ \langle \tau^{-1}(\tilde{\beta}, x), \Xi \rangle = \langle \tau^{-1}(\tilde{\beta} \cap x), \Xi \rangle \]
(identifying $x$ with $x \otimes 1 \in X(g, d) \otimes \mathcal{L}(t) = HF^-(\Sigma \times S^1, s_k; \mathcal{L}(t))$). Indeed, it follows from Theorem 9.4 and Remark 9.5 that we can write
\[ \tilde{\beta} \cdot x = \tilde{\beta} \cap x + \sum_{n \geq 1} t^{nk} \rho_n(\tilde{\beta}, x) \]
for some elements $\rho_n(\tilde{\beta}, x) \in X(g, d)$. Since $\tilde{\beta} \cdot x$ is homogeneous (with respect to the $\mathbb{Z}$ grading in which $t$ carries degree $-2k$), we infer that the $\rho_n(\tilde{\beta}, x)$ lie in degrees of $X(g, d)$ other than that of $\tilde{\beta} \cap x$. That is, these elements carry different height from $\tilde{\beta} \cap x$, and hence pair trivially with $\Xi$.

On the other hand, if $k = 0$ then corrections to the $H_1$ action $\tilde{\beta} \cdot x$ appear in the same height as $\tilde{\beta} \cap x$. Since the action is standard to leading order in $t$, however, we can say that for basis elements $\beta, \gamma$ as previously the action satisfies $\tilde{\beta} \cdot \gamma = \delta_{\beta \gamma} u_\beta(t) \cdot 1$, where $u_\beta \in \mathcal{L}(t)$ is monic (in the sense that the coefficient of the lowest power of $t$ is 1, cf Remark 9.5) and hence a unit in $\mathcal{L}(t)$ (here we observe that if $\tilde{\beta} \cap \gamma = 0$ then also $\tilde{\beta} \cdot \gamma = 0$). When $k = 0$, then, the above becomes
\[ \langle \tau^{-1}(\tilde{\beta}, x), \Xi \rangle = u_\beta \langle \tau^{-1}(\tilde{\beta} \cap x), \Xi \rangle. \]

Now suppose $\xi$ is an element of a given height in $HF^-(\Sigma \times S^1, s_k; \mathcal{L}(t))$. Then fixing the basis $B_{g, d} = \{ \beta \}$ as previously, we can express $\xi$ in terms of $\{ \beta \}$ by
\[ \xi = \left\{ \begin{array}{ll} \sum_{\beta} \langle \tau^{-1}(\tilde{\beta}, \xi), \Xi \rangle \cdot \beta & \text{if } k \neq 0 \\ \sum_{\beta} \langle \tau^{-1}(\tilde{\beta}, \xi), \Xi \rangle \cdot u_\beta^{-1} \beta & \text{if } k = 0. \end{array} \right. \]

where the sum is over basis elements $\beta$ having the degree equal to the height of $\xi$, and we have chosen the lowest-height generator 1 for $X(g, d)$ such that $\langle \tau^{-1}(1), \Xi \rangle = 1$.

Applying this idea to the case $\xi = \rho(\Psi_{\Sigma, \eta, s}(a_1))$ leads to the following.

**Proposition 10.6** Let $M$ be a closed 4–manifold containing an embedded surface $\Sigma$ of genus $g > 1$ and trivial normal bundle, and $\eta \in H^2(M; \mathbb{R})$ a class with $\int_\Sigma \eta > 0$. Write $Z = M \setminus (\Sigma \times D^2)$, and let $s$ be a spin$^c$ structure on $M$ restricting to $s_k$ on $\Sigma \times S^1$.

*Geometry & Topology, Volume 12 (2008)*
If $0 < |k| < g - 1$, then for an element $\alpha \in \mathbb{A}(Z)$, the reduced relative invariant $\rho(\Psi_Z, \eta, s(\alpha))$ is given in terms of a basis \{\beta\} for $HF_*^-(\Sigma \times S^1, s_k; \mathcal{L}(t))$ by

$$\rho(\Psi_Z, \eta, s(\alpha)) = \sum_{\beta} \Phi_{M, \Sigma \times S^1, \eta, s}(\alpha \otimes \tilde{\beta}) \cdot \beta,$$

where \{\tilde{\beta}\} $\subset \mathbb{A}(\Sigma \times D^2)$ are elements dual in the above sense to the basis \{\beta\}. If $k = 0$, then

$$\rho(\Psi_Z, \eta, s(\alpha)) = \sum_{\beta} \Phi_{M, \Sigma \times S^1, \eta, s}(\alpha \otimes \tilde{\beta}) \cdot u_{\beta}^{-1} \cdot \beta,$$

where $u_{\beta} \in \mathcal{L}(t)$ are units depending only on the basis \{\beta\}.

In the expressions above, $\alpha \otimes \tilde{\beta}$ is shorthand for the image of that element under the natural map $\mathbb{A}(Z) \otimes \mathbb{A}(\Sigma \times D^2) \to \mathbb{A}(M)$.

**Proof** When $k \neq 0$, we expand $\rho(\Psi_Z, \eta, s(\alpha))$ in the basis $\beta$ as indicated previously:

$$\rho(\Psi_Z, \eta, s(\alpha)) = \sum_{\beta} \langle \tau^{-1}(\tilde{\beta}, \rho(\Psi_Z, \eta, s(\alpha))), \Xi \rangle \cdot \beta$$

$$= \sum_{\beta} (-1)^{\deg(\tilde{\beta})} \tau^{-1}(\rho(\Psi_Z, \eta, s(\alpha))), \tilde{\beta}, \Xi \rangle \cdot \beta$$

$$= \sum_{\beta} (-1)^{\deg(\tilde{\beta})} \tau^{-1}(\rho(\Psi_Z, \eta, s(\alpha))), \Psi_{\Sigma \times D^2, \eta, s_k}(\tilde{\beta}) \rangle \cdot \beta$$

$$= \sum_{\beta} \Phi_{M, \Sigma \times S^1, \eta, s}(\alpha \otimes \tilde{\beta}) \cdot \beta,$$

up to an overall sign and translation by a power of $t$, where we sum only over those $\beta$ whose degree is equal to the height of $\rho(\Psi_Z, \eta, s(\alpha))$. The case $k = 0$ is identical except for the introduction of the elements $u_{\beta}^{-1}$.

### 10.3 Fiber sum formulas

A minor technicality in deducing the formulae in the introduction is the presence of the orientation-reversing gluing map in the fiber sum construction. We will have occasion to refer to the map in Floer homology induced by this diffeomorphism, so we make a few basic observations.

First, if $f: Y \to Y'$ is an orientation-preserving diffeomorphism between 3–manifolds, we can construct the mapping cylinder $C_f = (Y \times [0, 1]) \cup_f (Y' \times \{1\})$ in the usual way, which we can view as a smooth cobordism $Y \to Y'$ of oriented manifolds. The action

*Geometry & Topology, Volume 12 (2008)*
of \( f \) on Floer homology is by definition the homomorphism \( F_{Cf}^\circ \) in Floer homology induced by \( C_f \). We will normally write this action as \( f_* \).

It is easy to see from basic properties of the cobordism maps that if \( h \in H_1(Y) \) then for \( x \in HF^\circ(Y) \) we have \( f_*(hx) = f_*(h) \cdot f_*(x) \). In twisted coefficients, there is an isomorphism \( f_* = (f^{-1})^*: \mathbb{Z}[H^1(Y';\mathbb{Z})] \to \mathbb{Z}[H^1(Y';\mathbb{Z})] \), and for \( \alpha \in \mathbb{Z}[H^1(Y';\mathbb{Z})] \) we have \( f_*(\alpha x) = f_*(\alpha) f_*(x) \). A similar statement holds in the perturbed case, if \( Y \) is equipped with a class \( \eta_1 \in H^2(Y;\mathbb{R}) \) and we take \( \eta_2 = (f^{-1})^*\eta_1 \).

In the case of a fiber sum, we are given two closed 4–manifolds \( M_1, M_2 \) with embedded surfaces \( \Sigma_1, \Sigma_2 \) of genus \( g \) and square 0. Write \( Z_i = M_i \setminus (\Sigma_i \times D^2) \), so that \( \partial Z_i = \Sigma \times S^1 \). Then we choose an orientation-preserving diffeomorphism \( \phi \) between \( \Sigma_1 \) and \( \Sigma_2 \), extending it to \( \Sigma \times S^1 \) by conjugation in the \( S^1 \) factor. The result is an orientation-reversing diffeomorphism \( f: \partial Z_2 \to \partial Z_1 \), and the fiber sum is defined to be \( X = Z_1 \cup_f Z_2 \). To make the gluing \( f \) more explicit, replace \( Z_2 \) by \( W_2 = Z_2 \cup_{\phi} C_f \). Then \( X = Z_1 \cup W_2 \), and the relative invariants of \( W_2 \) and \( Z_2 \) are related by \( \Psi_{W_2} = f_* \Psi_{Z_2} \), according to the composition law. Thus both \( \Psi_{Z_2} \) and \( \Psi_{Z_2} \) naturally take values in \( HF^\circ(-\Sigma \times S^1) \) (with appropriate coefficients), while \( \Psi_{W_2} \) takes values in \( HF^\circ(\Sigma \times S^1) \).

Note that in certain situations, the above observations are sufficient to determine the action of \( f_* \). For example, if the genus of \( \Sigma \) is 1, then the reduced perturbed Floer homology \( HF^-((-\Sigma \times S^1); L(t)) \) is isomorphic to \( L(t) \), where \( t \) is Poincaré dual to the torus \( \Sigma \). Since the action of \( f \) in cohomology reverses the sign of the latter class, linearity of the induced map in Floer homology forces \( f_*: HF^-((-\Sigma \times S^1); L(t)) \to HF^-((-\Sigma \times S^1); L(t)) \) to be the conjugation map \( L(t) \to \overline{L(t)} \), up to multiplication by \( \pm t^n \). Hence, the same conclusion follows in perturbed Floer homology, using a class \( \eta \in H^2(-\Sigma \times S^1;\mathbb{R}) \) fixed by \( f^* \), e.g., the Poincaré dual to \([S^1]\). A similar conclusion holds when considering the action of the gluing map in higher genus, if we restrict attention to the highest (or lowest) nontrivial heights in the perturbed Floer homology.

The fiber sum formula in the genus 1 case is as follows.

**Theorem 10.7** Let \( X = M_1 \#_{T_1} T_2 M_2 \) be the fiber sum of two 4–manifolds \( M_1, M_2 \) along tori \( T_1, T_2 \) of square 0. Assume that there exist classes \( \eta_i \in H^2(M_i;\mathbb{R}) \), \( i = 1, 2 \), such that the restrictions of \( \eta_i \) to \( T_i \times S^1 \subset M_i \) correspond under the gluing diffeomorphism \( f: T_2 \times S^1 \to T_1 \times S^1 \), and assume that \( \int_{T_1} \eta_1 > 0 \). Let \( \eta \in H^2(X;\mathbb{R}) \) be a class whose restrictions to \( Z_i = M_i \setminus (T_i \times D^2) \) agree with those of \( \eta_i \), and choose spin\(^c\) structures \( s_i \in \text{Spin}^c(M_i) \), \( s \in \text{Spin}^c(X) \) whose restrictions correspond similarly. Then for any \( \alpha \in \mathbb{A}(X) \), the image of \( \alpha_1 \otimes \alpha_2 \) under the map \( \mathbb{A}(Z_1) \otimes \mathbb{A}(Z_2) \to \mathbb{A}(X) \),
we have
\[ \rho(\Phi_{X,T} \times S^1, \eta_s(\alpha)) = (t^{1/2} - t^{-1/2})^2 \Phi_{\mathbf{M}_1, T_1 \times S^1, \eta_1, \eta_1}(\alpha_1) \cdot \Phi_{\mathbf{M}_2, T_2 \times S^1, \eta_2, \eta_2}(\alpha_2) \]
up to multiplication by \( \pm t^n \).

Note that the closed invariants \( \Phi_{\mathbf{M}_1, T_1 \times S^1, \eta_1, \eta_1} \) each take values in \( \mathcal{L}(t) \), where \( t \) is the appropriate generator of \( K(M_1, T_1 \times S^1) \), and the multiplication takes place in that Laurent series ring.

**Proof** By definition,
\[ \Phi_{X,T} \times S^1, \eta_s(\alpha) = (\tau^{-1}(\Psi_{Z_1, \eta_1}(\alpha_1)), \Psi_{W_2, \eta_2, \eta_2}(\alpha_2)), \]
where \( W_2 = Z_2 \cup C_f \) as in the remarks above. Applying \( \rho \) to each side, we see
\[ \rho(\Phi_{X,T} \times S^1, \eta_s(\alpha)) = (\tau^{-1}(\Psi_{Z_1, \eta_1}(\alpha_1)), f_s(\rho(\Psi_{Z_2, \eta_2, \eta_2}(\alpha_2)))). \]
Since \( f_s(\rho(\Psi_{Z_2, \eta_2, \eta_2}(\alpha_2))) = \rho(\Psi_{Z_2, \eta_2, \eta_2}(\alpha_2)) \), the theorem follows quickly from this, Proposition 10.3, and antilinearity of \( \langle \cdot, \cdot \rangle \). Observe that the pairing in Floer homology of \( T \times S^1 \) can only be multiplication, up to \( \pm t^n \), since the modules are cyclic. \( \square \)

The higher-genus case is similarly easy, after some preparatory remarks. Recall that given a (homogeneous) basis \( \{\beta_i\} \) for \( X(g, d) \), we obtain a “dual” collection \( \{\tilde{\beta}_i\} \) of elements of \( \mathcal{A}(\Sigma) = \Lambda^* H_1(\Sigma) \otimes \mathbb{Z}[U] \). This dual basis is defined by the condition that \( \tilde{\beta}_i \cap \beta_j = \delta_{ij} \), where \( \cap \) is the standard action of \( \mathcal{A}(\Sigma) \) on \( X(g, d) \). The dual basis satisfies \( (\tau^{-1}(\tilde{\beta}_j, \beta_i), \Xi) = \delta_{ij} u_i \), where \( \Xi \) is the usual topmost generator of \( HF^-(-\Sigma \times S^1, s_k; \mathcal{L}(t)) \), \( \tilde{\beta}_j, \beta_i \) denotes the action of \( \mathcal{A}(\Sigma) \) on Floer homology, and \( u_i \) is a unit in \( \mathcal{L}(t) \) that equals 1 unless \( k = 0 \). Furthermore, the basis \( \{\tilde{\beta}_i\} \) is unique if we specify that it is contained in the subgroup \( \tilde{X}(g, d) = \bigoplus_{i=0}^d \Lambda^i H_1(\Sigma) \otimes \mathbb{Z}[U]/U^{d-i+1} \subset \mathcal{A}(\Sigma) \).

If \( \{\tilde{\beta}_i\} \) is the “Kronecker dual” basis, we can find a “Poincaré dual” basis \( \{\beta_i^\circ\} \) for \( X(g, d) \), namely \( \beta_i^\circ = \tilde{\beta}_i \cap (1 \otimes U^{-d}) \), where we think of \( 1 \otimes U^{-d} \) as a topmost generator for the Floer homology \( X(g, d) \otimes \mathcal{L}(t) = HF^-(-\Sigma \times S^1, s_k; \mathcal{L}(t)) \). We could also say that \( \beta_i^\circ \) is the leading order part (in \( t \)) of \( \tilde{\beta}_i, \Xi \), except that in our conventions, \( \Xi \) is a generator for \( HF^-(-\Sigma \times S^1, s_k; \mathcal{L}(t)) \).

Associated to the basis \( \{\beta_i^\circ\} \), of course, there is a dual \( \{\tilde{\beta}_i^\circ\} \), generating a subset of \( \mathcal{A}(\Sigma) \). This set satisfies \( \beta_i^\circ \cap \beta_j^\circ = \tilde{\beta}_i^\circ \cap \beta_j \cap (1 \otimes U^{-d}) = \delta_{ij} \).

With these conventions in mind, we have the following.
Assume also that

Otherwise, writing

Applying Proposition 10.5, this is

Hence the above is equal to

Suppose now that each of

Choose the basis

for bases

A to a basis for

Along surfaces

Product formulae for Ozsváth–Szabó 4–manifold invariants

As in the previous theorem,

Let

Theorem 10.8

Let

be the fiber sum of two 4–manifolds

along surfaces

such that

and square 0. Let

be 2–dimensional cohomology classes satisfying conditions analogous to those in the previous theorem, and choose spin$^c$ structures

and

restricting compatibly as before. If the Chern classes of each spin$^c$ structure restrict to

as a class other than

with

then the Ozsváth–Szabó invariants of all manifolds involved vanish.

Otherwise, writing

for the gluing map

we have

\[
\rho(\Phi_X, \Sigma \times S^1, \eta, s(a)) = \sum_\beta \Phi_{M_1, \Sigma \times S^1, \eta_1, s_1} (\alpha_1 \otimes \beta) \cdot \Phi_{M_2, \Sigma \times S^1, \eta_2, s_2} (\alpha_2 \otimes f_*^{-1}(\beta^0)) \cdot u_\beta
\]

up to multiplication by $\pm t^n$. Here

is a basis for

associated to a basis for

and

and

are the dual elements of

described above. The elements

are units that are equal to 1 unless $k = 0$.

**Proof** As in the previous theorem,

\[
\rho(\Phi_X, \Sigma \times S^1, \eta, s(a)) = \langle \tau^{-1} \rho(\Psi_{Z_1, \eta_1, s_1}(\alpha_1)), f_* \rho(\Psi_{Z_2, \eta_2, s_2}(\alpha_2)) \rangle.
\]

Applying Proposition 10.5, this is

\[
\left\langle \tau^{-1} \sum_i \Phi_{M_1, \Sigma \times S^1, \eta_1, s_1} (\alpha_1 \otimes \beta_i) \cdot \beta_i, f_* \sum_j \Phi_{M_2, \Sigma \times S^1, \eta_2, s_2} (\alpha_2 \otimes \gamma_j) \cdot \gamma_j \right\rangle
\]

for bases

whose relationship will be determined momentarily. As before,

is conjugate-linear in

and the pairing is also conjugate-linear in the second variable. Hence the above is equal to

\[
\sum_{i,j} \Phi_{M_1, \Sigma \times S^1, \eta_1, s_1} (\alpha_1 \otimes \beta_i) \Phi_{M_2, \Sigma \times S^1, \eta_2, s_2} (\alpha_2 \otimes \gamma_j) (\tau^{-1}(\beta_i), f_*(\gamma_j)).
\]

Choose the basis

by setting

from this it is easy to see that

The result follows immediately.

Suppose now that each of

have

so that Theorem 8.17 applies to identify the perturbed invariants

with the usual Ozsváth–Szabó invariants

Assume also that

restricts to a nonzero multiple of

in the theorem above. The coefficient change

sums the coefficients of

corresponding to spin\(^c\) structures differing by rim tori, so since \(k \neq 0\), Theorem 10.8 translates to the equation

\[
\sum_n \Phi^\text{Rim}_{X,s+n_1}(\alpha) t^n = \sum_{\beta, n_1, n_2} \Phi_{M_1,s+n_1 t_1}(\alpha \otimes \tilde{\beta}) \Phi_{M_2,s_2+n_2 t_2}(\alpha_2 \otimes f_*^{-1}(\tilde{\beta}^\circ)) t^{n_1+n_2},
\]

where \(t_i\) is Poincaré dual to the class of \(\Sigma_i\) in \(M_i\), and \(t\) is simultaneously the dual of \(\Sigma\) in \(X\) and the formal variable in \(L(t)\). The above holds after possibly a multiplication by a power of \(t\); thus equating coefficients yields the formula

\[
\Phi^\text{Rim}_{X,s}(\alpha) = \sum_{n_1+n_2=n_0} \Phi_{M_1,s+n_1 t_1}(\alpha \otimes \tilde{\beta}) \Phi_{M_2,s_2+n_2 t_2}(\alpha_2 \otimes f_*^{-1}(\tilde{\beta}^\circ))
\]

for some fixed integer \(n_0\).

Now, if \(\{\tilde{\beta}\}\) is a basis of homogeneous elements, it is not hard to see that \(\{\tilde{\beta}^\circ\}\) are likewise homogeneous of complementary degree. Specifically, if \(\deg(\tilde{\beta}) = m\) in \(\tilde{X}(g,d) \subset \mathbb{A}(\Sigma)\) then \(\deg(\tilde{\beta}^\circ) = 2d - m\) (as usual, \(d = g - 1 - |k|\)). Thus in the above formula, we have

\[
\deg(\alpha \otimes \tilde{\beta}) + \deg(\alpha_2 \otimes f_*^{-1}(\tilde{\beta}^\circ)) = \deg(\alpha) + 2g - 2 - 2|k|.
\]

On the other hand, if a spin\(^c\) 4–manifold \((N, \tau)\) has \(\Phi_{N,v}(\xi) \neq 0\) for \(\xi \in \mathbb{A}(N)\) then we must have \(\deg(\xi) = d(\tau)\). Substituting this in the above and using \(\sigma(X) = \sigma(M_1) + \sigma(M_2)\) and \(e(X) = e(M_1) + e(M_2) + 4g - 4\) gives

\[
(37) \quad c^1_t(s) = c^1_t(s_1 + n t_1) + c^1_t(s_2 + n t_2) + 8|k|.
\]

When \(k = 0\), of course, changing \(s_i\) by multiples of \(t_i\) does not affect the self-intersection so that (37) holds in that case as well.

This observation motivates the following “patching” construction producing elements of \(H^2(X; \mathbb{Z})\) (modulo rim tori) from certain pairs of elements in \(H^2(M_i; \mathbb{Z})\). We find it easiest to describe this construction in homology rather than cohomology; the homological version is obtained by Poincaré duality. Suppose, then, that \(x_1 \in H_2(M_1)\) and \(x_2 \in H_2(M_2)\) are integral homology classes, represented by embedded surfaces also denoted \(x_1, x_2\), and assume that \(x_i, \Sigma_i = m\) for \(i = 1, 2\). Let \(\rho: H_2(M_1) \to H_2(Z_i, \partial Z_i)\) denote the composition of the natural map \(H_2(M_1) \to H_2(M_i, \Sigma_i \times D^2)\) followed by the excision isomorphism of the latter group with \(H_2(Z_i, \partial Z_i)\) where \(Z_i = M_i \setminus \text{int}(\Sigma_i \times D^2)\). Consider the long exact sequence for \(X = Z_1 \cup_\beta Z_2:\)

\[
\cdots \to H_2(\Sigma \times S^1) \to H_2(X) \to H_2(Z_1, \partial Z_1) \oplus H_2(Z_2, \partial Z_2) \to H_1(\Sigma \times S^1) \to \cdots
\]
The condition on $x_i, \Sigma_i$ and the fact that the $\rho(x_i)$ are restrictions of classes on the closed manifolds $M_i$ imply that there exists a lift $x \in H_2(X)$ of $(\rho(x_1), \rho(x_2))$, uniquely determined up to the image of $H_2(\Sigma \times S^1)$.

Choose the surfaces $x_i$ to intersect $\Sigma_i \times D^2$ in a collection of normal disks; at the expense of increasing the genus of the $x_i$ we may assume that there are exactly $|m|$ such disks. Then removing $\Sigma_i \times D^2$ from each of $M_1, M_2$ and gluing we can obtain a smooth surface representing the lifted class $x$. It is clear that $x$ has $x.\Sigma = m$, and furthermore by using pushoffs of the $x_i$ that are disjoint from the normal disks in $\Sigma_i \times D^2$ we see that the self-intersection of $x$ satisfies $x^2 = x_1^2 + x_2^2$.

Now let $x_1 * x_2 = x + 2\epsilon \Sigma$, where $\epsilon$ is the sign of $m$. Then the self-intersection of $x_1 * x_2$ is

$$(x_1 * x_2)^2 = x_1^2 + x_2^2 + 4|m|,$$

and moreover the class $x_1 * x_2$ is determined by this condition up to addition of elements of $H_2(\Sigma \times S^1)/[\Sigma]$, in other words, up to rim tori.

The multiplication in Theorem 1.1 is the Poincaré dual of this patching construction; the proof of that theorem is immediate from Theorem 10.8 and the remarks leading to (37). Theorem 1.4 follows similarly from Theorem 10.7.

11 Manifolds of simple type

Corollary 1.2 is an easy consequence of the fiber sum formula. Indeed, if $M_1$ and $M_2$ have simple type, then the only contributions to the right hand side of (1) are those in which $\alpha_1, \alpha_2, \beta$ and $\beta^\circ$ have degree zero. Hence $\alpha = \alpha_1 \otimes \alpha_2$ also has degree 0, showing that $\rho(\mathcal{O}_{X,\sigma}(\alpha)) = 0$ unless $\deg(\alpha) = 0$, which is the first statement of the corollary. Furthermore, since $\beta$ and $\beta^\circ$ have complementary degree in $\bar{X}(g, d)$, their degrees can both be 0 only if $|k| = g - 1$, which gives (2).

In the case of a 4–manifold containing a torus of square 0, we have the following analog of a result of Morgan, Mrowka and Szabó [7] in Seiberg–Witten theory. Recall that a 4–manifold $X$ containing a surface $\Sigma$ is said to have $\Lambda(\Sigma)$–simple type if all Ozsváth–Szabó invariants of $X$ vanish on elements of $\Lambda(X)$ lying in the ideal generated by $U$ and $H_1(\Sigma)$.

**Proposition 11.1** Suppose $X$ is a closed 4–manifold with $b^+(X) \geq 2$ containing a torus $T \subset X$ of self-intersection 0 representing a class of infinite order in $H_2(X)$. Then $X$ has $\Lambda(T)$–simple type.
Proof By Theorem 8.17 we can write
\[ \Phi_{X,T^3,\eta,s}(\alpha) = \langle \tau^{-1} \Psi_{Z,\eta,s}(\alpha_1), \Psi_{T^2 \times D^2,\eta,s}(\alpha_2) \rangle, \]
for suitable perturbation $\eta$, and we may assume that $s|_{T^2 \times D^2} = s_0$, the torsion spin$^c$ structure. If $\alpha = \alpha' \cdot \alpha_T$ is in the ideal generated by $\mathbb{A}(T)$, where $\alpha' \in \mathbb{A}(X)$ and $\alpha_T \in \mathbb{A}(T)$, then we can take $\alpha_1 = \alpha'$ and $\alpha_2 = \alpha_T$. But $\Psi_{T^2 \times D^2,\eta,s_0}(\alpha_T) = \alpha_T \cdot \Psi_{T^2 \times D^2,\eta,s_0}(1)$, and the relative invariant $\Psi_{T^2 \times D^2,\eta,s_0}(1)$ lies in the only nontrivial degree of $HF^-(T^3, s_0; \mathcal{L}(t))$. Hence if $\deg \alpha_T > 0$ we have $\alpha_T \cdot \Psi_{T^2 \times D^2,\eta,s_0}(1) = 0$ and the result follows. \hfill \box

Note that the proof applies also to 4–manifolds with $b^+(X) = 1$, if we consider only the perturbed invariant $\Phi_{X,T^3,\eta,s}$ relative to the decomposition of $X$ along the boundary of a tubular neighborhood of the torus.
