Homological mirror symmetry for the quintic 3–fold

YUICHI NOHARA
KAZUSHIUEDA

We prove homological mirror symmetry for the quintic Calabi–Yau 3–fold. The proof follows that for the quartic surface by Seidel [16] closely, and uses a result of Sheridan [23]. In contrast to Sheridan’s approach [22], our proof gives the compatibility of homological mirror symmetry for the projective space and its Calabi–Yau hypersurface.

53D37; 14J33

1 Introduction

Ever since the proposal by Kontsevich [9], homological mirror symmetry has been proved for elliptic curves (see Polishchuk and Zaslow [14], Polishchuk [13] and Seidel [19]), Abelian surfaces (see Fukaya [5], Kontsevich and Soibelman [11] and Abouzaid and Smith [1]) and quartic surfaces (see Seidel [16]). It has also been extended to other contexts such as Fano varieties (see Kontsevich [10]), varieties of general type (see Katzarkov [8]), and singularities (see Takahashi [24]), and various evidences have been accumulated in each cases.

The most part of the proof of homological mirror symmetry for the quartic surface by Seidel [16] works in any dimensions. Combined with the results of Sheridan [23], an expert reader will observe that one can prove homological mirror symmetry for the quintic 3–fold if one can show that

- the large complex structure limit monodromy of the pencil of quintic Calabi–Yau 3–folds is negative in the sense of Seidel [16, Definition 7.1], and
- the vanishing cycles of the pencil of quintic Calabi–Yau 3–folds are isomorphic in the Fukaya category to Lagrangian spheres constructed by Sheridan [23].

We prove these statements, and obtain the following:
Theorem 1.1  Let $X_0$ be a smooth quintic Calabi–Yau 3–fold in $\mathbb{P}_C^4$ and $\mathcal{Z}_q$ be the mirror family. Then there is a continuous automorphism $\psi \in \text{End}(\Lambda_N)^\times$ and an equivalence

$$(1) \quad D^\pi \mathcal{F}(X_0) \cong \hat{\psi}^* D^b \text{coh} \mathcal{Z}_q^*$$

of triangulated categories over $\Lambda_Q$.

Here $\Lambda_N = \mathbb{C}[q]$ is the ring of formal power series in one variable and $\Lambda_Q$ is its algebraic closure. The automorphism $\hat{\psi}$ of $\Lambda_Q$ is any lift of the automorphism $\psi$ of $\Lambda_N$, and the category $\hat{\psi}^* D^b \text{coh} \mathcal{Z}_q^*$ is obtained from $D^b \text{coh} \mathcal{Z}_q^*$ by changing the $\Lambda_Q$–module structure by $\hat{\psi}$. The category $D^\pi \mathcal{F}(X_0)$ is the split-closed derived Fukaya category of $X_0$ consisting of rational Lagrangian branes. The symplectic structure of $X_0$ and hence the parameter $q$ come from 5 times the Fubini–Study metric of the ambient projective space $\mathbb{P}_C^4$. The mirror family $\mathcal{Z}_q = [Y_q/\Gamma]$ is the quotient of the hypersurface

$$Y_q^* = \{[y_1: \ldots : y_5] \in \mathbb{P}_L^4_{\Lambda_Q} \mid y_1 \ldots y_5 + q(y_1^5 + \cdots + y_5^5) = 0\}$$

by the group

$$\Gamma = \{(\text{diag}(a_1, \ldots , a_5)) \in PSL_5(\mathbb{C}) \mid a_1^5 = \cdots = a_5^5 = a_1 \cdots a_5 = 1\}.$$

Let $\mathcal{Z}_q = [Y_q/\Gamma]$ be the quotient of the hypersurface $Y_q$ of $\mathbb{P}_L^4_{\Lambda_N}$ defined by the same equation as $Y_q^*$ above. The equivalence (1) is obtained by combining the equivalences

$$D^\pi \mathcal{F}(X_0) \cong \hat{\psi}^* D^\pi \mathcal{S}_q^* \cong \hat{\psi}^* D^b \text{coh} \mathcal{Z}_q^*$$

for an $A_\infty$–algebra $\mathcal{S}_q^* = \mathcal{S}_q \otimes_{\Lambda_N} \Lambda_Q$ as follows:

1. The derived category $D^b \text{coh} \mathcal{Z}_q^*$ of coherent sheaves on $\mathcal{Z}_q^*$ has a split-generator, which extends to an object of $D^b \text{coh} \mathcal{Z}_q$. The quasi-isomorphism class of the endomorphism dg algebra $\mathcal{S}_q$ of this object is characterized by its cohomology algebra together with a couple of additional properties up to pull-back by $\text{End}(\Lambda_N)^\times$.

2. The Fukaya category $\mathcal{F}(X_0)$ contains 625 distinguished Lagrangian spheres. They are vanishing cycles for a pencil of quintic Calabi–Yau 3–folds, and a suitable combination of symplectic Dehn twists along them is isotopic to the large complex structure limit monodromy.

3. The large complex structure limit monodromy has a crucial property of negativity, which enables one to show that the vanishing cycles split-generate the derived Fukaya category $D^\pi \mathcal{F}(X_0)$. 

Geometry & Topology, Volume 16 (2012)
The total morphism $A_\infty$–algebra $F_q$ of the vanishing cycles has the same cohomology algebra as $S_q$ and satisfies the additional properties characterizing $S_q$.

The condition that $X_0$ is a 3–fold is used in the proof that vanishing cycles split-generate the Fukaya category, cf. Remarks 3.6 and 3.9. Sheridan [22] proved homological mirror symmetry for Calabi–Yau hypersurfaces in projective spaces along the lines of Sheridan [23]. In contrast to Sheridan’s approach, our proof is based on the relation between Sheridan’s immersed Lagrangian sphere in a pair of pants and vanishing cycles on Calabi–Yau hypersurfaces, and gives the compatibility of homological mirror symmetry for the projective space and its Calabi–Yau hypersurface as in Remark 5.11.

This paper is organized as follows: Sections 2 and 3 have little claim in originality, and we include them for the readers’ convenience. In Section 2, we recall the description of the derived category of coherent sheaves on $Z_q^*$ due to Seidel [16]. In Section 3, we extend Seidel’s discussion on the Fukaya category of the quartic surface to general projective Calabi–Yau hypersurfaces. Strictly speaking, the work of Fukaya, Oh, Ohta and Ono [6] that we rely on in this section gives not a full-fledged $A_\infty$–category but an $A_\infty$–algebra for a Lagrangian submanifold and an $A_\infty$–bimodule for a pair of Lagrangian submanifolds. While there is apparently no essential difficulty in generalizing their work to construct an $A_\infty$–category (for transversally intersecting sequence of Lagrangian submanifolds, one can regard it as a single immersed Lagrangian submanifold and use the work of Akaho and Joyce [2]), we do not attempt to settle this foundational issue in this paper. Sections 4 and 5 are at the heart of this paper. In Section 4, we prove the negativity of the large complex structure limit monodromy using ideas of Seidel [16] and Ruan [15]. In Section 5, we use ideas from Seidel [18] and Futaki and Ueda [7] to reduce Floer cohomology computations on vanishing cycles needed in Section 3 to a result of Sheridan [23].

Acknowledgments We thank Akira Ishii, Takeo Nishinou and Nick Sheridan for valuable discussions. We also thank the anonymous referees for helpful suggestions and comments. 2 Derived category of coherent sheaves

Let $V$ be an $(n+2)$–dimensional complex vector space spanned by $\{v_i\}_{i=1}^{n+2}$, and $\{y_i\}_{i=1}^{n+2}$ be the dual basis of $V^\vee$. The projective space $\mathbb{P}(V)$ has a full exceptional collection $(F_k = \Omega^{n+2-k}_{\mathbb{P}(V)}(n+2-k)(n+2-k))_{k=1}^{n+2}$ by Beilinson [3]. The full dg
subcategory of (the dg enhancement of) $D^b_{coh\mathbb{P}(V)}$ consisting of $(F_k)_{k=1}^{n+2}$ is quasi-isomorphic to the $\mathbb{Z}$–graded category $C_{n+2}$ with $(n + 2)$ objects $X_1, \ldots, X_{n+2}$ and morphisms

$$\text{Hom}_{C_{n+2}}(X_j, X_k) = \begin{cases} \Lambda^{k-j}V & j \leq k, \\ 0 & \text{otherwise}. \end{cases}$$

The differential is trivial, the composition is given by the wedge product, and the grading is such that $V$ is homogeneous of degree one. One can equip $(F_k)_{k=1}^{n+2}$ with a $GL(V)$–linearization so that this quasi-isomorphism is $GL(V)$–equivariant. Let $t_0: Y_0 \hookrightarrow \mathbb{P}(V)$ be the inclusion of the union of coordinate hyperplanes and set $E_{0,k} = t_0^*F_k$. The total morphism dg algebra $\bigoplus_{i,j=1}^{n+2}\text{hom}(E_{0,i}, E_{0,j})$ of this collection will be denoted by $S_{n+2}$.

Let $C_{n+2}$ be the trivial extension category of $C_{n+2}$ of degree $n$ as defined by Seidel [16, Section 10a]. It is a category with the same object as $C_{n+2}$. The morphisms are given by

$$\text{Hom}_{C_{n+2}}(X_j, X_k) = \text{Hom}_{C_{n+2}}(X_j, X_k) \oplus \text{Hom}_{C_{n+2}}(X_k, X_j)^\vee[-n],$$

and the compositions are given by

$$(a, a^\vee)(b, b^\vee) = (ab, a^\vee(b \cdot)) + (-1)^{\deg(a)(\deg(b)+\deg(b^\vee))}b^\vee(\cdot, a).$$

From this definition, one can easily see that

$$\text{Hom}_{C_{n+2}}(X_j, X_k) = \begin{cases} \Lambda^{k-j}V & j < k, \\ \Lambda^0V \oplus \Lambda^{n+2}V[2] & j = k, \\ \Lambda^{k-j+n+2}V[2] & j > k. \end{cases}$$

The total morphism algebra $Q_{n+2}$ of this category $C_{n+2}$ admits the following description: Set $\gamma = \zeta_{n+2} \text{id}_V$ for $\zeta_{n+2} = \exp(2\pi\sqrt{-1}/(n + 2))$ and let $\Gamma_{n+2} = \langle \gamma \rangle \subset SL(V)$ be a cyclic subgroup of order $n + 2$. The group algebra $R_{n+2} = \mathbb{C}\Gamma_{n+2}$ is a semisimple algebra of dimension $n + 2$, whose primitive idempotents are given by

$$e_j = \frac{1}{n+2}(e + \zeta_{n+2}^{-j} \gamma + \cdots + \zeta_{n+2}^{-(n+1)j} \gamma^{n+1}) \in \mathbb{C}\Gamma_{n+2}.$$ 

Let $\Lambda^j\mathbb{V} = \bigoplus_{i=0}^{n+2}\Lambda^i\mathbb{V}$ be the exterior algebra equipped with the natural $\mathbb{Z}$–grading and $\tilde{Q}_{n+2} = \Lambda V \rtimes \Gamma_{n+2}$ be the semidirect product. There is an $R_{n+2}$–algebra isomorphism between $\tilde{Q}_{n+2}$ and $Q_{n+2}$ sending $e_k\tilde{Q}_{n+2}e_j$ to $\text{Hom}_{C_{n+2}}(X_j, X_k)$. This isomorphism does not preserve the $\mathbb{Z}$–grading; $Q_{n+2}$ is obtained from $\tilde{Q}_{n+2}$ by assigning degree $\frac{n}{n+2}k$ to $\Lambda^kV \otimes \mathbb{C}\Gamma_{n+2}$ and adding $\frac{2}{n+2}(k - j)$ to the piece $e_k\tilde{Q}e_j$.
Let $H$ be a maximal torus of $SL(V)$ and $T$ be its image in $PSL(V) = SL(V)/\Gamma_{n+2}$. The group $T$ acts on $Q_{n+2}$ by an automorphism of a graded $R_{n+2}$–algebra so that $[\text{diag}(t_1, t_2, \ldots, t_{n+2})]$ sends $v \otimes e_i \in e_{i+1}Q_{n+2}e_i$ to $(\text{diag}(1, t_2/t_1, \ldots, t_{n+2}/t_1) \cdot v) \otimes e_i$.

The dg algebra $S_{n+2}$ is characterized by the following properties:

**Lemma 2.1** (Seidel [16, Lemma 10.2]) Assume that a $T$–equivariant $A_{\infty}$–algebra $Q_{n+2}$ over $R_{n+2}$ satisfies the following properties:

- The cohomology algebra $H^*(Q_{n+2})$ is $T$–equivariantly isomorphic to $Q_{n+2}$ as an $R_{n+2}$–algebra.
- $Q_{n+2}$ is not quasi-isomorphic to $Q_{n+2}$.

Then one has a $R_{n+2}$–linear, $T$–equivariant quasi-isomorphism $Q_{n+2} \sim S_{n+2}$.

**Sketch of proof** The proof of the fact that these properties are satisfied by $S_{n+2}$ is identical to Seidel [16, Section 10d]. The uniqueness comes from the Hochschild cohomology computations in [16, Section 10a]: The Hochschild cohomology of $\tilde{Q}_{n+2}$ is given by

$$HH^{s+t}(\tilde{Q}_{n+2}, \tilde{Q}_{n+2})' \cong \bigoplus_{\gamma \in \Gamma_{n+2}} (S^s(V)^{\vee} \otimes \Lambda^{s+t-\text{codim} V^\vee} (V^\vee) \otimes \Lambda^{\text{codim} V^\vee} (V/V^\vee))^\Gamma_{n+2},$$

where $SV = \bigoplus_{i=0}^{\infty} S^iV$ is the symmetric algebra of $V$ (see [16, Proposition 4.2]). By the change of the grading from $\tilde{Q}_{n+2}$ to $Q_{n+2}$, one obtains

$$HH^{s+t}(Q_{n+2}, Q_{n+2})' \cong \bigoplus_{\gamma \in \Gamma_{n+2}} (S^s(V)^{\vee} \otimes \Lambda^{s+n+2-t-\text{codim} V^\vee} (V^\vee) \otimes \Lambda^{\text{codim} V^\vee} (V/V^\vee))^\Gamma_{n+2}.$$

By passing to the $T$–invariant part, one obtains

$$(HH^2(Q_{n+2}, Q_{n+2})_{2-d})^T = (S^dV^{\vee} \otimes \Lambda^{n+2-d} V)^H$$

$$(3) \quad = \begin{cases} \mathbb{C} \cdot y_1 \cdots y_{n+2} & d = n+2, \\ 0 & \text{for all other } d > 2, \end{cases}$$

so that $S_{n+2}$ is determined by the above properties up to quasi-isomorphism [16, Lemma 3.2].
Let $\mathbb{P}_{\Lambda_N} = \mathbb{P}(V \otimes \mathbb{C} \Lambda_N)$ be the projective space over $\Lambda_N$ and $Y_q$ be the hypersurface defined by $q(y_1^{n+2} + \cdots + y_{n+2}^{n+2}) + y_1 \cdots y_{n+2} = 0$. The geometric generic fiber of the family $Y_q \to \text{Spec} \Lambda_N$ is the smooth Calabi–Yau variety $Y_q^* = Y_q \times_{\Lambda_N} \Lambda_Q$ appearing in Section 1, and the special fiber is $Y_0$ above. The collection $E_{0,k}$ is the restriction of the collection $E_{q,k}$ on $Y_q$ obtained from the Beilinson collection on $\mathbb{P}_{\Lambda_N}$, and its restriction to $Y_q^*$ split-generates $D^b \text{coh} Y_q^*$ by [16, Lemma 5.4].

Let $\Gamma$ be the abelian subgroup of $PSL_{n+2}(\mathbb{C})$ defined in (2). Each $E_{q,k}$ admits $(n+2)^n$ $\Gamma$–linearizations, so that one obtains $(n+2)^{n+1}$ objects of $D^b \text{coh} Z_q = D^b \text{coh} \Gamma Y_q$, whose total morphism dg algebra will be denoted by $S_q$. It is clear that their restriction to $Z_q^*$ split-generates $D^b \text{coh} Z_q^*$, so that one has the following:

**Lemma 2.2** There is an equivalence

$$D^b \text{coh} Z_q^* \cong D^\pi S_q^*$$

of triangulated categories, where $S_q^* = S_q \otimes_{\Lambda_N} \Lambda_Q$.

We write the inverse image of $\Gamma \subset PSL(V)$ by the projection $SL(V) \to PSL(V)$ as $\tilde{\Gamma}$, and set $Q = Q_{n+2} \times \Gamma = \Lambda V \times \tilde{\Gamma}$. Then the cohomology algebra of $S_q$ is given by $Q \otimes \Lambda N$, and the central fiber is $S_0 = S_{n+2} \times \Gamma$. As explained in [16, Section 3], first order deformations of the dg (or $A_{\infty}$–)algebra $S_0$ are parametrized by the truncated Hochschild cohomology $HH^2(S_0, S_0)_{\leq 0}$.

**Lemma 2.3** (Seidel [16, Lemma 10.5]) The truncated Hochschild cohomology of $S_0$ satisfies

$$HH^1(S_0, S_0)_{\leq 0} = \mathbb{C}^{n+1}, \quad HH^2(S_0, S_0)_{\leq 0} = \mathbb{C}^{2n+3}.$$

**Sketch of proof** There is a spectral sequence leading to $HH^*(S_0, S_0)_{\leq 0}$ such that

$$E_2^{s,t} = \begin{cases} HH^{s+t}(Q, Q) \otimes_{\Lambda} \Lambda^{s+t - \text{codim}_V V} (V/Y) \otimes \Lambda^t \text{codim}_V V (V/Y) \otimes \tilde{\Gamma} & t \leq 0, \\ 0 & \text{otherwise}. \end{cases}$$

The isomorphism

$$HH^{s+t}(Q, Q) \otimes_{\Lambda} \Lambda^{s+t - \text{codim}_V V} (V/Y) \otimes \Lambda^t \text{codim}_V V (V/Y) \otimes \tilde{\Gamma}$$

implies that $E_2^{s,t} = 0$ for $s < 0$ or $s + \frac{n+2}{n} t < 0$, which ensures the convergence of the spectral sequence. One can easily see that $E_2^{s,t}$ for $s + t \leq 2$ is non-zero only if $(s, t) = (0, 0), (1, 0), (2, 0), (n + 2, -n)$. 

*Geometry & Topology, Volume 16 (2012)*
The first nonzero differential is $\delta_{n+1}$, which is the Schouten bracket with the order $n + 2$ deformation class $y_1 \ldots y_{n+2}$ from (3). In total degree $s + t = 1$, we have the $\tilde{\Gamma}$--invariant part of $V^\vee \otimes V$, which is spanned by elements $y_k \otimes v_k$ satisfying

$$\delta_{n+1}^{1,0}(y_k \otimes v_k) = y_1 \ldots y_{n+2}$$

for $k = 1, \ldots, n + 2$. In total degree $s + t = 2$, we have

- $(S^2 V^\vee \otimes \Lambda^2 V)^{\tilde{\Gamma}}$ generated by $(n + 2)(n + 1)/2$ elements $y_j y_k \otimes v_j \wedge v_k$ satisfying

$$\delta_{n+1}^{2,0}(y_j y_k \otimes v_j \wedge v_k) = (y_1 \ldots y_{n+2})y_k \otimes v_k - (y_1 \ldots y_{n+2})y_j \otimes v_j,$$

- $(S^{n+2} V^\vee)^{\tilde{\Gamma}}$ spanned by $y_k^{n+2}$ together with $y_1 \ldots y_{n+2}$.

The kernel of $\delta_{n+1}^{1,0}$ is spanned by

$$y_1 \otimes v_1 - y_2 \otimes v_2$$

and its $n + 1$ cyclic permutations, which sum up to zero. The image of $\delta_{n+1}^{1,0}$ is spanned by $y_1 \ldots y_{n+2}$. The kernel of $\delta_{n+1}^{2,0}$ is spanned by

$$y_1 y_2 \otimes v_1 \wedge v_2 + y_2 y_3 \otimes v_2 \wedge v_3 - y_1 y_3 \otimes v_1 \wedge v_3$$

and its $n + 1$ cyclic permutations, which also sum up to zero. Differentials $\delta_{k}^{s,t}$ for $k > n + 1$ and $s + t \leq 2$ vanish, and one obtains the desired result. \qed

Unfortunately, the second truncated Hochschild cohomology group $HH^2(S_0, S_0)_{\leq 0}$ has multiple dimensions, so that one needs additional structures to characterize $S_q$ as a deformation of $S_0$. The strategy adopted by Seidel is to use a $\mathbb{Z}/(n + 2)\mathbb{Z}$--action coming from the cyclic permutation of the basis of $V$: Let $U_{n+2}$ be an automorphism of $Q_{n+2} = \Lambda V \rtimes \Gamma_{n+2}$ as an $R_{n+2}$--algebra, which acts on the basis of $V$ as $v_k \mapsto v_{k+1}$. This lifts to a $\mathbb{Z}/(n + 2)\mathbb{Z}$--action on $S_0 = S_{n+2} \rtimes \Gamma$, and $S_q$ is characterized as follows:

**Proposition 2.4** (Seidel [16, Proposition 10.8]) Let $Q_q$ be a one-parameter deformation of $S_0 = S_{n+2} \rtimes \Gamma$, which is

- $\mathbb{Z}/(n + 2)\mathbb{Z}$--equivariant, and
- non-trivial at first order.

Then $Q_q$ is quasi-isomorphic to $\psi^* S_q$ for some $\psi \in \text{End}(\Lambda_N)^\times$. 

*Geometry & Topology, Volume 16 (2012)*
The proof that these conditions characterize $S_q$ comes from the fact that the invariant part of the second truncated Hochschild cohomology of the central fiber $S_0$ with respect to the cyclic group action induced by $U_0$ is one-dimensional [16, Lemma 10.7];

$$HH^2(S_0, S_0)^{\leq 0, \mathbb{Z}/(n+2)\mathbb{Z}} \cong \mathbb{C} \cdot (y_1^{n+2} + \cdots + y_{n+2}^{n+2}).$$

The proof that these conditions are satisfied by $S_q$ carries over verbatim from [16, Section 10d].

3 Fukaya categories

Let $X = \text{Proj} \mathbb{C}[x_1, \ldots, x_{n+2}]$ be an $(n+1)$–dimensional complex projective space and $o_X$ be the anticanonical bundle on $X$. Let further $h$ be a Hermitian metric on $o_X$ such that the compatible unitary connection $\nabla$ has the curvature $-2\pi \sqrt{-1} \omega_X$, where $\omega_X$ is $n + 2$ times the Fubini–Study Kähler form on $X$. Any complex submanifold of $X$ has a symplectic structure given by the restriction of $\omega_X$. The restriction of $(o_X, \nabla)$ to any Lagrangian submanifold $L$ has a vanishing curvature, and $L$ is said to be rational if the monodromy group of this flat connection is finite. Note that this condition is equivalent to the existence of a flat multi-section $\lambda L$ of $o_X|L$ which is of unit length everywhere.

Two sections $\sigma_{X, \infty} = x_1 \ldots x_{n+2}$ and $\sigma_{X, 0} = x_1^{n+2} + \cdots + x_{n+2}^{n+2}$ of $o_X$ generate a pencil $\{X_z\}_{z \in \mathbb{P}_1}$ of hypersurfaces

$$X_z = \{x \in X | \sigma_{X, 0}(x) + z\sigma_{X, \infty}(x) = 0\},$$

such that $X_0$ is the Fermat hypersurface and $X_\infty$ is the union of $n + 2$ coordinate hyperplanes. The complement $M = X \setminus X_\infty$ is the big torus of $X$, which can naturally be identified as

$$M = \{x \in \mathbb{C}^{n+2} | x_1 \ldots x_{n+2} \neq 0\}/\mathbb{C}^* \cong \{x \in \mathbb{C}^{n+2} | x_1 \ldots x_{n+2} = 1\}/\Gamma_{n+2}^*,$$

where $\Gamma_{n+2}^* = \{\zeta \text{id}_{\mathbb{C}^{n+2}} | \zeta^{n+2} = 1\}$ is the kernel of the natural projection from $\text{SL}_{n+2}(\mathbb{C})$ to $\text{PSL}_{n+2}(\mathbb{C})$. The map

$$\pi_M = \sigma_{X, 0}/\sigma_{X, \infty}: M \to \mathbb{C}$$

is a Lefschetz fibration, which has $n + 2$ groups of $(n+2)^n$ critical points with identical critical values. The group $\Gamma^* = \text{Hom}(\Gamma, \mathbb{C}^*)$ of characters of the group $\Gamma$ defined in (2) acts freely on $M$ through a non-canonical isomorphism $\Gamma^* \cong \Gamma$ and the natural action of $\Gamma \subset \text{PSL}_{n+2}(\mathbb{C})$ on $X$. The quotient

$$\overline{M} = M/\Gamma^* = \{u = (u_1, \ldots, u_{n+2}) \in \mathbb{C}^{n+2} | u_1 \ldots u_{n+2} = 1\}$$

Geometry & Topology, Volume 16 (2012)
Homological mirror symmetry for the quintic 3–fold

Figure 1: The distinguished set \((\delta_i)^{n+2}_{i=1}\) of vanishing paths

is another algebraic torus, where the natural projection \(M \to \overline{M}\) is given by \(u_k = x_k^{n+2}\). The map \(\pi_M\) is \(\Gamma^*\)-invariant and descends to the map \(\pi_{\overline{M}}(u) = u_1 + \cdots + u_{n+2}\) from the quotient

\[
\begin{array}{ccc}
M & \overset{\pi_M}{\longrightarrow} & \mathbb{C} \\
\downarrow & & \downarrow \pi_{\overline{M}} \\
\overline{M} & & \\
\end{array}
\]

The map \(\pi_{\overline{M}}: \overline{M} \to \mathbb{C}\) is the Landau–Ginzburg potential for the mirror of \(\mathbb{P}^{n+1}\), which has \(n+2\) critical points with critical values \(\{(n+2)\zeta^{-i}_{n+2}\}_{i=1}^{n+2}\) where \(\zeta_{n+2} = \exp\left[2\pi \sqrt{-1}/(n+2)\right]\). Choose the origin as the base point and take the distinguished set \((\delta_i)^{n+2}_{i=1}\) of vanishing paths \(\delta_i: [0, 1] \ni t \mapsto (n+2)\zeta^{-i}_{n+2} t \in \mathbb{C}\) as in Figure 1. The corresponding vanishing cycles in \(\overline{M}_0 = \pi_{\overline{M}}^{-1}(0)\) will be denoted by \(V_i\).

Let \(\mathcal{F}_{n+2}\) be the \(A_\infty\)-category whose set of objects is \(\{V_i\}_{i=1}^{n+2}\) and whose spaces of morphisms are Lagrangian intersection Floer complexes. This is a full \(A_\infty\)-subcategory of the Fukaya category \(\mathcal{F}(\overline{M}_0)\) of the exact symplectic manifold \(\overline{M}_0\). See Seidel [20] for the Fukaya category of an exact symplectic manifold, and Fukaya, Oh, Ohta and Ono [6] for that of a general symplectic manifold. We often regard the \(A_\infty\)-category \(\mathcal{F}_{n+2}\) with \(n+2\) objects as an \(A_\infty\)-algebra over the semisimple ring \(R_{n+2}\) of dimension \(n+2\).

As explained in Section 5 below, the affine variety \(\overline{M}_0\) is an \((n+2)\)-fold cover of the \(n\)-dimensional pair of pants \(\mathcal{P}^n\), and contains \(n+2\) Lagrangian spheres \(\{L_i\}_{i=1}^{n+2}\) whose projection to \(\mathcal{P}^n\) is the Lagrangian immersion studied by Sheridan [23].
$A_{n+2}$ be the full $A_\infty$–subcategory of $\mathcal{F}(\overline{M_0})$ consisting of these Lagrangian spheres. The following proposition is proved in Section 5:

**Proposition 3.1** The Lagrangian submanifolds $L_i$ and $V_i$ are isomorphic in $\mathcal{F}(\overline{M_0})$.

The inclusion $\overline{M_0} \subset \overline{M}$ induces an isomorphism $\pi_1(\overline{M_0}) \cong \pi_1(\overline{M})$ of the fundamental group. Let $T$ be the torus dual to $\overline{M}$ so that $\pi_1(\overline{M}) \cong T^* := \text{Hom}(T, \mathbb{C}^\times)$. One can equip $\mathcal{F}_{n+2}$ with a $T$–action by choosing lifts of $V_i$ to the universal cover of $\overline{M_0}$. Let $\mathcal{F}_0$ be the Fukaya category of $M_0$ consisting of $N = (n + 2)^{n+1}$ vanishing cycles $\{\overline{V}_i\}^N_{i=1}$ of $\pi_M$ obtained by pulling-back $\{V_i\}^{n+2}_{i=1}$. The covering $M_0 \to \overline{M_0}$ comes from a surjective group homomorphism $\pi_1(\overline{M_0}) \to \Gamma^*$, which induces an inclusion $\Gamma \hookrightarrow T$ of the dual group. It follows from Seidel [16, Equation (8.13)] that $\mathcal{F}_0$ is quasi-isomorphic to $\mathcal{F}_{n+2} \rtimes \Gamma$, which in turn is quasi-isomorphic to $A_{n+2} \rtimes \Gamma$ by Proposition 3.1.

The following proposition is due to Sheridan:

**Proposition 3.2** (Sheridan [23, Proposition 5.15]) $A_{n+2}$ is $T$–equivariantly quasi-isomorphic to $S_{n+2}$.

Since $S_0 = S_{n+2} \rtimes \Gamma$, one obtains the following:

**Corollary 3.3** $\mathcal{F}_0$ is quasi-isomorphic to $S_0$.

The vanishing cycles $\{\overline{V}_i\}^N_{i=1}$ are Lagrangian submanifolds of the projective Calabi–Yau manifold $X_0$, which are rational since they are contractible in $M$. To show that they split-generate the Fukaya category of $X_0$, Seidel introduced the notion of negativity of a graded symplectic automorphism. Let $\mathcal{L}_{X_0} \to X_0$ be the bundle of unoriented Lagrangian Grassmannians on the projective Calabi–Yau manifold $X_0$. The phase function $\alpha_{X_0} : \mathcal{L}_{X_0} \to S^1$ is defined by

$$\alpha_{X_0}(\Lambda) = \frac{\eta_{X_0}(e_1 \wedge \ldots \wedge e_n)^2}{|\eta_{X_0}(e_1 \wedge \ldots \wedge e_n)|^2},$$

where $\Lambda = \text{span}_\mathbb{R}\{e_1, \ldots, e_n\} \in \mathcal{L}_{X_0,x}$ is a Lagrangian subspace of $T_x X_0$ and $\eta_{X_0}$ is a holomorphic volume form on $X_0$. The phase function $\alpha_\phi : \mathcal{L}_{X_0} \to S^1$ of a symplectic automorphism $\phi : X_0 \to X_0$ is defined by sending $\Lambda \in \mathcal{L}_{X_0,x}$ to $\alpha_\phi(\Lambda) = \alpha_{X_0}(\phi_\ast(\Lambda))/\alpha_{X_0}(\Lambda)$, and a graded symplectic automorphism is a pair $\phi = (\phi, \alpha_\phi)$ of a symplectic automorphism $\phi$ and a lift $\tilde{\alpha}_\phi : \mathcal{L}_{X_0} \to \mathbb{R}$ of the phase function $\alpha_\phi$ to the universal cover $\mathbb{R}$ of $S^1$. The group of graded symplectic automorphisms of $X_0$ will
be denoted by $\widetilde{\text{Aut}}(X_0)$. A graded symplectic automorphism $\tilde{\phi} \in \widetilde{\text{Aut}}(X_0)$ is negative if there is a positive integer $d_0$ such that $\widetilde{\alpha}_{\tilde{\phi}^{d_0}}(\Lambda) < 0$ for all $\Lambda \in \mathcal{L}_{X_0}$.

The phase function $\alpha_L: L \to S^1$ of a Lagrangian submanifold $L \subset X_0$ is defined similarly by $\alpha_L(x) = \alpha_{X_0}(T_xL)$, and a grading of $L$ is a lift $\tilde{\alpha}_L: L \to \mathbb{R}$ of $\alpha_L$ to the universal cover of $S^1$. Let $\Lambda_0$ be the local subring of $\Lambda_{Q}$ containing only non-negative powers of $q$, and $\Lambda_+ = \Lambda_0$ be the maximal ideal of $\Lambda_0$. For a quintuple $(L^\#, \alpha_L, \sigma_L, \lambda_L, J_L)$ consisting of a rational Lagrangian submanifold $L$, a grading $\tilde{\alpha}_L$ on $L$, a spin structure $\sigma_L$ on $L$, a multi-section $\lambda_L$ of $\sigma_{X_0}|L$, and a compatible almost complex structure $J_L$, one can endow the cohomology group $H^*(L; \Lambda_0)$ with the structure $(\mathfrak{m}_k)_{k=0}^\infty$ of a filtered $A_{\infty}$-algebra (see Fukaya, Oh, Ohta and Ono [6, Definition 3.2.20]), which is well-defined up to isomorphism [6, Theorem A].

The map $\mathfrak{m}_0: \Lambda_0 \to H^1(L; \Lambda_0)$ comes from holomorphic disks bounded by $L$, and measures the anomaly or obstruction to the definition of Floer cohomology. A solution $b \in H^1(L; \Lambda_+)$ to the Maurer–Cartan equation

$$
\sum_{k=0}^{\infty} \mathfrak{m}_k(b, \ldots, b) = 0
$$

is called a bounding cochain. A rational Lagrangian brane is a pair $L^\hat{\cdot} = (L^\#, b)$ of $L^\#$ and a bounding cochain $b \in H^1(L; \Lambda_+)$. For a pair $L_1^\hat{\cdot} = (L_1^\#, b_1)$ and $L_2^\hat{\cdot} = (L_2^\#, b_2)$ of rational Lagrangian branes, the Floer cohomology $HF(L_1^\hat{\cdot}, L_2^\hat{\cdot}; \Lambda_0)$ is well-defined up to isomorphism. The Fukaya category $F(X_0)$ is an $A_{\infty}$-category over $\Lambda_{Q}$ whose objects are rational Lagrangian branes and whose spaces of morphisms are Lagrangian intersection Floer complexes.

Let $F_q$ be the full $A_{\infty}$-subcategory of $F(X_0)$ consisting of vanishing cycles $\tilde{V}_i$ equipped with the trivial complex line bundles, the canonical gradings and zero bounding cochains. Since the restrictions of $(\sigma_X, \nabla)$ to vanishing cycles are trivial flat bundles, the category $F_q$ is defined over $\Lambda_{\mathbb{N}}$.

Let $\eta_M$ be the unique up to scalar holomorphic volume form on $M$ which extends to a rational form on $X$ with a simple pole along $X_\infty$. This gives a holomorphic volume form $\eta_M/dz$ on each fiber $M_z = \pi_M^{-1}(z)$, so that $\pi_M: M \to \mathbb{C}$ is a locally trivial fibration of graded symplectic manifolds outside the critical values. Let $\gamma_\infty: [0, 2\pi] \to \mathbb{C}$ be a circle of large radius $R \gg 0$ and $\tilde{\gamma}_\infty \in \widetilde{\text{Aut}}(M_M)$ be the monodromy along $\gamma_\infty$. Since $\gamma_\infty$ is homotopic to a product of paths around each critical values, one sees that $\tilde{\gamma}_\infty$ is isotopic to a composition of Dehn twists along vanishing cycles. We prove the following in Section 4:

**Proposition 3.4** (Seidel [16, Proposition 7.22]) The graded symplectic automorphism $\tilde{\gamma}_\infty \in \widetilde{\text{Aut}}(M_M)$ is isotopic to a graded symplectic automorphism $\tilde{\phi} \in \widetilde{\text{Aut}}(M_M)$ whose
extension to \(X_R\) has the following property: There is an arbitrary small neighborhood \(W \subset X_R\) of the subset \(\text{Sing}(X_\infty) \cap X_R\) such that \(\phi(W) = W\) and \(\phi|_{X_R \cap W}\) is negative.

Here \(\text{Sing}(X_\infty)\) is the singular locus of \(X_\infty\), which is the union of \((n-1)\)-dimensional projective spaces.

**Lemma 3.5** (Seidel [16, Lemma 9.2]) If \(n = 3\), then any rational Lagrangian brane is contained in split-closed derived category of \(\mathcal{F}_q^* = \mathcal{F}_q \otimes_{\Lambda_{\mathbb{N}}} \Lambda_{\mathbb{Q}};\)

\[
D^q \mathcal{F}(X_0) \cong D^q \mathcal{F}_q^*.
\]

The proof is identical to that of Seidel [16, Lemma 9.2], which is based on Seidel’s long exact sequence [17] (see also [16, Section 9c] and Oh [12]).

**Remark 3.6** (Seidel [16, Remark 9.3]) If \(n = 3\), then the real dimension of the intersection \(\text{Sing}(X_\infty) \cap X_0\) is two, so that any Lagrangian submanifold can be made disjoint from a sufficiently small neighborhood \(W\) of \(\text{Sing}(X_\infty) \cap X_0\) by a generic perturbation. This is the only place where we use the condition \(n = 3\), and one can show the equivalence (1) for any \(n\) with \(D^q \mathcal{F}(X_0)\) replaced by the split-closure of Lagrangian branes which can be perturbed away from \(\text{Sing}(X_\infty) \cap X_0\).

A notable feature of Floer cohomologies over \(\Lambda_0\) is their dependence on Hamiltonian isotopy: For a pair \((L_0^\#, L_1^\#)\) of Lagrangian submanifolds equipped with auxiliary choices, a symplectomorphism \(\psi\) induces an isomorphism

\[
\psi_*: \left(H^*(L_i^\#; \Lambda_0), m_k\right) \rightarrow \left(H^*(\psi(L_i^\#); \Lambda_0), m_k\right)
\]

of filtered \(\Lambda_{\mathbb{Q}}\)-algebras (see Fukaya, Oh, Ohta and Ono [6, Theorem A]), which induces a map \(\psi_*\) on the set of bounding cochains preserving the Floer cohomology over \(\Lambda_0\) [6, Theorem G.3]:

\[
HF((L_0^\#, b_0), (L_1^\#, b_1); \Lambda_0) \cong HF((\psi(L_0^\#), \psi_*(b_0)), (\psi(L_1^\#), \psi_*(b_1)); \Lambda_0).
\]

On the other hand, if we move \(L_0^\#\) and \(L_1^\#\) by two distinct Hamiltonian isotopies \(\psi^0\) and \(\psi^1\), then the Floer cohomology over \(\Lambda_{\mathbb{Q}}\) is preserved [6, Theorem G.4]

\[
HF((L_0^\#, b_0), (L_1^\#, b_1); \Lambda_{\mathbb{Q}}) \cong HF((\psi^0(L_0^\#), \psi^0_*(b_0)), (\psi^1(L_1^\#), \psi^1_*(b_1)); \Lambda_{\mathbb{Q}}),
\]

whereas the Floer cohomology over \(\Lambda_0\) may not be preserved;

\[
HF((L_0^\#, b_0), (L_1^\#, b_1); \Lambda_0) \ncong HF((\psi^0(L_0^\#), \psi^0_*(b_0)), (\psi^1(L_1^\#), \psi^1_*(b_1)); \Lambda_0).
\]

See [6, Section 3.7.6] for a simple example where this occurs. This phenomenon is used by Seidel [16, Section 8g and 11a] to prove the following:
Proposition 3.7  (Seidel [16, Proposition 11.1])  The $A_\infty$–algebra $\mathcal{F}_q \otimes_{\Lambda_N} \Lambda_N/q^2 \Lambda_N$ is not quasi-isomorphic to the trivial deformation $\mathcal{F}_0 \otimes_{\mathbb{C}} \Lambda_N/q^2 \Lambda_N$.

To show this, Seidel takes a rational Lagrangian submanifold $L_{1/2}$ in $X_2$ for sufficiently large $z$ as follows:

1. Consider a pencil $\{X_z\}_{z \in \mathbb{P}^1}$ generated by two sections $\sigma_{X,\infty} = x_1 \ldots x_{n+2}$ and $\sigma_{X,0} = x_1^2(x_2^2 + x_3^2)x_4 \ldots x_{n+1}$, whose general fiber is singular. Let $C = \{x_{n+2} = 0\}$ be an irreducible component of $X_\infty = \{x_1 \ldots x_{n+2} = 0\} \subset X$, and $C_\infty = C \cap X_\infty$ be the intersection with other components. If we write $C_0 = X_0 \cap C$, then the set $C_0 \setminus C_\infty$ is the union of two $(n-1)$–planes $\{x_2 = \pm \sqrt{-1}x_3\}$.

2. Let $K_{1/2} = \{2|x_1| = |x_2| = \cdots = |x_{n+2}|\} \subset C \setminus C_\infty$ be a Lagrangian $n$–torus in $C$, which is a fiber of the moment map for the torus action. The intersection $K_{1/2} \cap C_0$ consists of two $(n-1)$–tori.

3. Take a Hamiltonian function $H$ on $C$ supported on a neighborhood of the two $(n-1)$–tori such that the corresponding Hamiltonian vector field points in opposite directions transversally to two $(n-1)$–tori. By flowing $K_{1/2}$ along the Hamiltonian vector field in both negative and positive time directions, one obtains a family $(K_r)_{r \in [0,1]}$ of Lagrangian submanifolds of $C \setminus C_\infty$.

4. The Lagrangian submanifolds $K_r$ for $r \neq 1/2$ are disjoint from $C_0$. They are exact Lagrangian submanifolds with respect to the one-form $\theta_{C \setminus C_0}$ obtained by pulling back the connection on $\sigma_X$ via $\sigma_{X,0}|_{C \setminus C_0}$.

5. Now perform a generic perturbation of $\sigma_{X,0}$ so that a general member $X_z$ of the pencil is smooth. One still has a Lagrangian submanifold $K_{1/2} \subset C \setminus C_\infty$ satisfying the following:

- $K_{1/2} \cap C_0$ consists of two $(n-1)$–tori.
- By flowing $K_{1/2}$ along a Hamiltonian vector field, one obtains a family $(K_r)_{r \in [0,1]}$ of Lagrangian submanifolds of $C \setminus C_\infty$.
- $K_r$ for $r \neq 1/2$ are disjoint from $C_0$. They are exact Lagrangian submanifolds of $C \setminus C_0$.

6. By parallel transport along the graph

$$\hat{X} = \{(y, x) \in \mathbb{C} \times X \mid \sigma_{X,\infty}(x) = y\sigma_{X,0}(x)\} \xrightarrow{y\text{–projection}} \mathbb{C}$$

of the pencil, one obtains a Lagrangian torus $L_{1/2}$ in $X_2$ for sufficiently large $z = 1/y$, satisfying the following conditions:
• The intersection $Z = L_{1/2} \cap X_{z,\infty}$ of $L_{1/2} \cong (S^1)^n$ with the divisor $X_{z,\infty} = X_z \cap X_{\infty}$ at infinity is a smooth $(n-1)$-dimensional manifold disjoint from $\text{Sing}(X_{\infty}) \cap X_z$. (In fact, it is a disjoint union of two $(n-1)$-tori; $Z = \{1/4, 3/4\} \times (S^1)^{n-1}$.)

• By flowing $L_{1/2}$ by a Hamiltonian vector field, one obtains a family $(L_r)_{r \in [0, 1]}$ of Lagrangian submanifolds of $X_z$.

• $L_r$ for any $r \in [0, 1]$ admits a grading.

• $L_r$ for $r \neq 1/2$ are disjoint from $X_{z,\infty}$. They are exact Lagrangian submanifolds in the affine part $M_z = X_z \setminus X_{z,\infty}$ of $X_z$.

If the perturbation of $\sigma_{X,0}$ is generic, then there are no non-constant stable holomorphic disks in $X_z$ bounded by $L_r$ for $r \in [0, 1]$ with area less than 2. Indeed, such a disk cannot have a sphere component since a holomorphic sphere has area at least $n + 2$. If a holomorphic disk exists in $X_z$ for all sufficiently large $z$, then Gromov compactness theorem gives a holomorphic disk in $X_{\infty}$ bounded by $K_r$. This disk either has sphere components in irreducible components of $X_{\infty}$ other than $C$, or passes through $C_{\infty} \cap C_0$. The former is impossible since sphere components have area at least $n + 2$, and the latter is impossible for a disk of area less than 2 since such disks have fixed intersection points with $C_{\infty}$ by classification (see Cho [4, Theorem 10.1]) of holomorphic disks in $C$ bounded by $K_r$.

The absence of holomorphic disks of area less than 2 shows that the Lagrangian submanifolds $L_0 = (L_0^\circ, 0)$ and $L_1 = (L_1^\circ, 0)$ equipped with auxiliary data and the zero bounding cochains give objects of the first order Fukaya category $D^\pi_q \otimes_{\Lambda_N} \Lambda_N/q^2\Lambda_N$. Now the argument of Seidel [16, Section 8g] shows the following:

(1) The spaces $H^0(\text{hom}_{\mathcal{F}_0}(L_i^\circ, L_j^\circ))$ are one-dimensional for $0 \leq i \leq j \leq 1$.

(2) The product

$$H^0(\text{hom}_{\mathcal{F}_0}(L_1^\circ, L_0^\circ)) \otimes H^0(\text{hom}_{\mathcal{F}_0}(L_0^\circ, L_1^\circ)) \rightarrow H^0(\text{hom}_{\mathcal{F}_0}(L_0^\circ, L_0^\circ))$$

vanishes.

(3) The map

$$H^0(\text{hom}_{\mathcal{F}_q}(L_1^\circ, L_0^\circ) \otimes_{\Lambda_N} \Lambda_N/q^2\Lambda_N) \otimes CH^0(\text{hom}_{\mathcal{F}_q}(L_0^\circ, L_1^\circ) \otimes_{\Lambda_N} \Lambda_N/q^2\Lambda_N)$$

induced by $m_{2q}^{F_q}$ is non-zero.
The point is that $L_0$ and $L_1$ are exact Lagrangian submanifolds of $M_z$, which are not isomorphic in $\mathcal{F}(M_z)$, but are Hamiltonian isotopic in $X_z$, so that they are isomorphic in $D^\pi (\mathcal{F}_q \otimes \Lambda_{\mathbb{N}} \Lambda_{\mathbb{Z}})$. Now [16, Lemma 3.9] concludes the proof of Proposition 3.7.

The symplectomorphism $\tilde{\phi}_0: \tilde{M}_0 \to \tilde{M}_0$ sending $(u_1, \ldots, u_{n+2})$ to $(u_2, \ldots, u_{n+2}, u_1)$ lifts to a $\mathbb{Z}/(n+2)$–action on $\mathcal{F}_q$ just as in [16, Section 11b]. It follows that $\mathcal{F}_q$ satisfies all the properties characterizing $S_q$ in Proposition 2.4, and one obtains the following;

**Proposition 3.8** $\mathcal{F}_q$ is quasi-isomorphic to $\psi^* S_q$ for some $\psi \in \text{End}(\Lambda_{\mathbb{N}})^\times$.

Theorem 1.1 follows from Lemma 2.2, Lemma 3.5, and Proposition 3.8.

**Remark 3.9** Since the Lagrangian torus used in the proof of Proposition 3.7 does not intersect with $\text{Sing}(X_\infty)$, the proof of Proposition 3.7 (and hence Proposition 3.8) works for any $n$. Then the argument of Sheridan [22, Section 8.2], based on a split-generation criterion announced by Abouzaid, Fukaya, Oh, Ohta, and Ono, shows that $\{L_i\}_{i=1}^{n+2}$ split-generates $D^\pi \mathcal{F}(X_0)$ for any $n$.

## 4 Negativity of monodromy

In this section, we prove Proposition 3.4 by using local models of the quasi-Lefschetz pencil $\{X_z\}$ along the lines of Seidel [16, Section 7]. In the case where $\dim X_z \geq 3$, we need [16, Assumption 7.8] and a generalization of [16, Assumption 7.5].

**Assumption 4.1** (Seidel [16, Assumption 7.8]) Let $n \geq 2$ and $2 \leq k \leq n + 1$.

- $Y \subset \mathbb{C}^{n+1} = \mathbb{R}^{2n+2}$ is an open ball around the origin equipped with the standard symplectic form $\omega_Y$ and the $T^k$–action $\rho_s(y) = (e^{\sqrt{-1}s_1} y_1, \ldots, e^{\sqrt{-1}s_k} y_k, y_{k+1}, \ldots, y_{n+1})$ with moment map $\mu: Y \to \mathbb{R}^k$. For any regular value $r \in \mathbb{R}^k$ of $\mu$, the symplectic reduction $Y_{\text{red}} = Y_{\text{red}, r} = \mu^{-1}(r)/T^k$ can be identified with an open subset in $\mathbb{C}^{n+1-k}$ equipped with the standard symplectic form.

- $J_Y$ is a complex structure on $Y$ which is tamed by $\omega_Y$. At the origin, it is $\omega_Y$–compatible and $T^k$–invariant.

- $p: Y \to \mathbb{C}$ is a $J_Y$–holomorphic function with the following properties:

  1. $p(\rho_s(y)) = e^{\sqrt{-1}(s_1 + \cdots + s_k)} p(y)$.
  2. $\partial_{y_1} \cdots \partial_{y_k} p$ is nonzero at $y = 0$.
• \( \eta_Y \) is a \( J_Y \)-complex volume form on \( Y \setminus p^{-1}(0) \) such that \( p(y)\eta_Y \) extends smoothly on \( Y \), which is nonzero at \( y = 0 \).

In this situation, the monodromy \( h_\xi \) satisfy the following:

**Proposition 4.2** (Seidel [16, Lemma 7.16]) For every \( d > 0 \) and \( \epsilon > 0 \), there exists \( \delta > 0 \) such that the following holds. For every \( y \in Y_\xi = p^{-1}(\xi) \) with \( 0 < \xi < \delta \) and \( \|y\| < \delta \), and every Lagrangian subspace \( \Lambda^v \subset T_yY_\xi \), the \( d \)-fold monodromy \( h^d_\xi \) is well-defined near \( y \), and satisfies

\[
\bar{\alpha}_{h^d_\xi}(\Lambda^v) \leq -2d + n + 1 + \epsilon.
\]

The other local model is the following:

**Assumption 4.3** Let \( n \geq 2 \) and \( 2 \leq k \leq n + 1 \).

• \( Y \subset \mathbb{C}^{n+1} = \mathbb{R}^{2n+2} \) is an open ball around the origin equipped with the standard symplectic form \( \omega_Y \) and the \( T^k \)-action

\[
\rho_s(y) = (e^{\sqrt{-1}s_1}y_1, \ldots, e^{\sqrt{-1}s_k}y_k, y_{k+1}, \ldots, y_{n+1})
\]

with moment map \( \mu: Y \to \mathbb{R}^k \). For any regular value \( r \in \mathbb{R}^k \) of \( \mu \), the symplectic reduction \( Y_{\text{red}} = Y_{\text{red},r} = \mu^{-1}(r)/T^k \) can be identified with an open subset in \( \mathbb{C}^{n+1-k} \) equipped with the standard symplectic form.

• \( J_Y \) is a complex structure on \( Y \) which is tamed by \( \omega_Y \). At the origin, it is \( \omega_Y \)-compatible and \( T^k \)-invariant.

• \( p \) is a \( J_Y \)-meromorphic function on \( Y \) satisfying the following two conditions:

(i) \( p(\rho_s(y)) = e^{\sqrt{-1}(-s_1+s_2+\cdots+s_k)}p(y) \).

This implies that \( p \) can be written as

\[
p(y) = \frac{y_2 \cdots y_k}{y_1} q(\|y_1\|^2/2, \ldots, \|y_k\|^2/2, y_{k+1}, \ldots, y_{n+1})
\]

for some \( q \).

(ii) \( q \) is a smooth function defined on \( Y \), \( q(0) = 1 \), and \( q(y) \neq 0 \) for any \( y \in Y \).

• \( \eta_Y \) is a \( J_Y \)-complex volume form on \( Y \setminus p^{-1}(0) \) such that \( y_2 \cdots y_k \eta_Y \) extends smoothly on \( Y \). It is normalized so that \( y_2 \cdots y_k \eta_Y = dy_1 \wedge \cdots \wedge dy_{n+1} \) at \( y = 0 \).

In this setting, we will show the negativity of the monodromy in the following sense:
Proposition 4.4 (Seidel [16, Lemma 7.16]) For any \( d > 0 \) and \( \epsilon > 0 \), there is \( \delta_1 > \delta_2 > 0 \) such that for \( \zeta \in \mathbb{C} \) with \( 0 < |\zeta| < \delta_1 \) and \( y \in Y_\zeta \) with \( \|y\| < \delta_1 \) and \( |y_1| > \delta_2 \), the \( d \)-fold monodromy \( h^d_\zeta \) is well-defined, and

\[
\tilde{\alpha}^d_\zeta(\Lambda^v) \leq -2d \frac{1}{1 + |\zeta|^2/|y_3|^{2(k-1)}} + n + 1 + \epsilon
\]

for all \( \Lambda^v \in Y_\zeta \), provided \( |y_2| \leq |y_3| \leq \cdots \leq |y_k| \).

Note that

\[
\frac{1}{1 + |\zeta|^2/|y_3|^{2(k-1)}}
\]

is uniformly bounded from above on the complement of a neighborhood of \( y_2 = y_3 = 0 \).

Let \( J'_Y \) be the constant complex structure on \( Y \) which coincides with \( J_Y \) at the origin, and let \( \eta'_Y \) be the constant \( J'_Y \)-complex volume form given by

\[
\eta'_Y = dy_1 \wedge \frac{dy_2}{y_2} \wedge \cdots \wedge \frac{dy_k}{y_k} \wedge \eta'_{Y,\text{red}}
\]

for some \( \eta'_{Y,\text{red}} \). The phase functions corresponding to \( \eta_Y \) and \( \eta'_Y \) are denoted by \( \alpha_Y \) and \( \alpha'_Y \), respectively. The proof of the following lemma is parallel to that in [16]:

Lemma 4.5 (Seidel [16, Lemma 7.12]) For any \( \epsilon > 0 \), there exists \( \delta > 0 \) such that if \( \|y\| < \delta \) and \( p(y) \neq 0 \) then

\[
\left| \frac{1}{2\pi} \arg(\alpha_Y(\Lambda)/\alpha'_Y(\Lambda)) \right| < \epsilon
\]

for all \( \Lambda \in \mathcal{L}_{Y,Y} \).

Let \( H(y) = -\frac{1}{2}|p(y)|^2 \) and consider its Hamiltonian vector field \( X \) and flow \( \phi_t \). For a regular value \( r \) of \( \mu \), the induced function, Hamiltonian vector field, and its flow on \( Y_{\text{red}} \) are denoted by

\[
H^\text{red}(y_{\text{red}}) = -2^{k-3} \frac{r_2 \cdots r_k}{q(r_1, \ldots, r_k, y_{k+1}, \ldots, y_{n+1})}.
\]

\( X_{\text{red}} \) and \( \phi^\text{red} \) respectively. We write the complex structure on \( Y_{\text{red}} \) induced from \( J'_Y \) as \( J'_{Y,\text{red}} \). Then \( \eta'_{Y,\text{red}} \) gives a \( J'_{Y,\text{red}} \)-complex volume form on \( Y_{\text{red}} \). Let \( \alpha'_{Y,\text{red}} \) be the phase function corresponding to \( \eta'_{Y,\text{red}} \). The proof of the following lemma is the same as in [16]:

Geometry \\& Topology, Volume 16 (2012)
Lemma 4.6 (Seidel [16, Lemma 7.13]) For any $\epsilon > 0$, there is $\delta > 0$ such that for $\|r\| < \delta$, $r_2 \ldots r_k / r_1 < \delta$, $\|y\text{red}\| < \delta$, and $|t| < \delta r_1 / r_2 \ldots r_k$, $\phi_t\text{red}$ is well-defined and
\[ \left| \tilde{\alpha}_{\phi_t}^{\text{red}}(\Lambda^{\text{red}}) \right| < \epsilon \]
for any Lagrangian subspace $\Lambda^{\text{red}}$.

Now we prove the following:

Lemma 4.7 (Seidel [16, Lemma 7.14]) For any $\epsilon > 0$, there is $\delta_1 > \delta_2 > 0$ such that if $\|y\| < \delta_1$, $|y_1| > \delta_2$, $0 < |p(y)| < \delta_1$ and $|t| < \delta_1 |p(y)|^{-2}$, then $\phi_t$ is well-defined and satisfies
\[ \left| \tilde{\alpha}_{\phi'_t}(\Lambda) - \frac{2t}{2\pi} \left( 1 + \frac{|y_1|^2}{|y_2|^2} + \cdots + \frac{|y_1|^2}{|y_k|^2} \right) \right| < n + 1 + \epsilon \]
for any $\Lambda \in \mathcal{L}_{Y,y}$.

Proof The proof of well-definedness of $\phi_t$ is parallel to [16]. Note that the condition $|y_1| > \delta_2$ is preserved under the flow since $\phi_t$ is $T^k$–equivariant. Let $H' = \frac{1}{2} |y_2 \ldots y_k / y_1|^2$ and
\[ X' = -\sqrt{-1} \left( \frac{1}{|y_1|^2} + \cdots + \frac{1}{|y_k|^2} \right)^{-1} \left( - \frac{y_1}{|y_1|^2}, \frac{y_2}{|y_2|^2}, \ldots, \frac{y_k}{|y_k|^2} \right) \]
be its Hamiltonian vector field. Then $H(y) = H'(y) r(y)$ for some smooth function $r(y) = 1 + O(\|y\|)$. By direct computation, we have
\[ \|dH'\| \leq C \left| \frac{y_2 \ldots y_k}{y_1} \right|^2 \left( \frac{1}{|y_1|^2} + \cdots + \frac{1}{|y_k|^2} \right) \leq C \left| \frac{y_2 \ldots y_k}{y_1} \right|^2 k \|y\|^{2(k-1)} \left| y_1 \ldots y_k \right|^2 \]
\[ = C \frac{k \|y\|^{2(k-1)}}{|y_1|^4}, \]
which is bounded if $\|y\| < \delta_1$ and $|y_1| > \delta_2$. Then
\[ \|dH - dH'\| \leq |r - 1| \|dH'\| + |H'| \|dr\| \leq C(\|y\| + |H'|), \]
and this implies that $\|dH - dH'\|$ is small if $|H|$ is also sufficiently small. Hence we obtain
\[ \|X - X'\| < \epsilon \]
for small $\delta_1$. Take a Lagrangian subspace $\Lambda^\text{red}$ in $T_{y_1}^\text{red}Y$ and consider a Lagrangian subspace given by

$$\Lambda = \sqrt{-1} y_1 \mathbb{R} \oplus \cdots \oplus \sqrt{-1} y_k \mathbb{R} \oplus \Lambda^\text{red} \subset T_y Y.$$ 

Then we have

$$\alpha_Y'(\Lambda) = (-1)^k \frac{y_1^2}{|y_1|^2} \cdot \alpha_Y'(\Lambda^\text{red}),$$

and hence

$$\bar{\alpha}_{\phi_t}'(\Lambda) = \frac{1}{2\pi} \int_0^t X \arg(\alpha_Y'((D\phi_\tau(\Lambda)))d\tau$$

$$= \frac{1}{2\pi} \int_0^t X' \arg \frac{y_1^2}{|y_1|^2} d\tau + \frac{1}{2\pi} \int_0^t (X-X') \arg \frac{y_1^2}{|y_1|^2} d\tau$$

$$+ \frac{1}{2\pi} \int_0^t X^\text{red} \arg(\alpha_Y'(\Lambda^\text{red}((D\phi_t^\text{red}(\Lambda^\text{red}))))d\tau.$$ 

The third term is small from Lemma 4.6. The second term is bounded by

$$\frac{1}{2\pi} \int_0^t \|X - X'\| D \arg \frac{y_1^2}{|y_1|^2} d\tau,$$

which is also small from (5) and the fact that

$$\left\| D \arg \frac{y_1^2}{|y_1|^2} \right\| \leq C \|X\| = C \|dH\|$$

is uniformly bounded. Since $|y_1|^2$ is preserved under the flow, the first term is

$$\frac{1}{2\pi} \int_0^t X' \arg \frac{y_1^2}{|y_1|^2} d\tau$$

$$= \frac{1}{2\pi} \left( \frac{1}{|y_1|^2} + \cdots + \frac{1}{|y_k|^2} \right)^{-1} \int_0^t \frac{1}{|y_1|^2} \sqrt{-1} y_1 \partial_{y_1} \arg \frac{y_1^2}{|y_1|^2} d\tau$$

$$= \frac{1}{2\pi} \left( \frac{1}{|y_1|^2} + \cdots + \frac{1}{|y_k|^2} \right)^{-1} \frac{2t}{|y_1|^2}$$

$$= \frac{2t}{2\pi} \left( 1 + \frac{|y_1|^2}{|y_2|^2} + \cdots + \frac{|y_1|^2}{|y_k|^2} \right)^{-1}.$$ 

Then we obtain

$$\left| \bar{\alpha}_{\phi_t}'(\Lambda) - \frac{2t}{2\pi} \left( 1 + \frac{|y_1|^2}{|y_2|^2} + \cdots + \frac{|y_1|^2}{|y_k|^2} \right)^{-1} \right| < \epsilon.$$
For arbitrary Lagrangian subspace $\Lambda_1$, the desired bound for $\tilde{\alpha}'_{\phi_t}(\Lambda_1)$ is obtained from this and the fact that

$$|\tilde{\alpha}'_{\phi_t}(\Lambda_1) - \tilde{\alpha}'_{\phi_t}(\Lambda)| < n + 1$$

(see [16, Lemma 6.11]).

Let $Z$ be the horizontal lift of $-\sqrt{-1}\xi \partial_{\xi}$, and $\psi_t$ be its flow. Then there is a positive function $f$ such that $Z = fX$, and hence $\psi_t(y) = \phi_{g_t(y)}(y)$ for

$$g_t(y) = \int_0^t f(\psi_\tau(y))d\tau.$$

By the same argument as in [16], we have:

**Lemma 4.8** (Seidel [16, Lemma 7.15]) For any $d > 0$ and $\epsilon > 0$, there is $\delta > 0$ such that for $\xi \in \mathbb{C}$ with $0 < |\xi| < \delta$ and $y \in Y_\xi = p^{-1}(\xi)$ with $\|y\| < \delta$, the $d$–fold monodromy $h_\xi^d$ is well-defined, $\epsilon / |\xi|^2 > 2\pi d$, and satisfies

$$g_{2\pi d}(y) \leq \epsilon / |\xi|^2.$$

**Proof of Proposition 4.4** Let $\eta_{Y_\xi} = \eta_Y / (d\xi / \xi^2)$ be a complex volume form on $Y_\xi$, and $\alpha_{Y_\xi}$ be the corresponding phase function. Take $\Lambda \in \mathfrak{L}_{Y,Y}$ such that $Dp(\Lambda) = a\mathbb{R}$ for $a \in U(1)$, and set $\Lambda^v = \Lambda \cap \ker Dp \in \mathfrak{L}_{Y_\xi,Y}$. Then

$$\alpha_{Y_\xi}(\Lambda^v) = \frac{\xi^4}{a^2|\xi|^4} \alpha_Y(\Lambda).$$

We consider a Lagrangian subspace $\Lambda^v \in \mathfrak{L}_{Y_\xi,Y}$ such that $Dp(\Lambda^v) = \sqrt{-1}\xi \mathbb{R}$, and containing the tangent space of the torus action on $Y_\xi$. Then $\Lambda^v$ has the form

$$\Lambda^v = (\sqrt{-1}y_1\mathbb{R} \oplus \cdots \oplus \sqrt{-1}y_k\mathbb{R} \oplus \Lambda^\text{red}) \cap \ker Dp.$$

Let $\Lambda = \Lambda^v \oplus Z_y\mathbb{R} \in \mathfrak{L}_{Y,Y}$. Since $Z$ is the horizontal lift of $-\sqrt{-1}\xi \partial_{\xi} \in T_\xi(\sqrt{-1}\xi \mathbb{R})$, $Z_{\psi_t(y)}$ is contained in $D\psi_t(\Lambda)$, and hence we have

$$D(\psi_t|_{Y_\xi})(\Lambda^v) = D\psi_t(\Lambda) \cap \ker(Dp).$$

From this and (6) we have

$$\alpha_{\psi_t|_{Y_\xi}}(\Lambda^v) = e^{-2it} \alpha_{\psi_t}(\Lambda).$$
Combining this with Lemma 4.5 and 4.7, we obtain

\[ \tilde{\alpha}_{h^d}(\Lambda^u) = \tilde{\alpha}_{g_{2 \pi d}}(\Lambda) - 2d \]

\[ \leq \tilde{\alpha}'_{g_{2 \pi d}}(\Lambda) - 2d + \epsilon \]

\[ \leq 2d \left( \left( 1 + \frac{|y_1|^2}{|y_2|^2} + \cdots + \frac{|y_1|^2}{|y_k|^2} \right)^{-1} - 1 \right) + \epsilon \]

\[ = -2d \frac{1}{|y_2|^2} + \cdots + \frac{1}{|y_k|^2} + \epsilon \]

\[ \leq -2d \frac{1}{1 + |\xi|^2/|y_3|^2(k-1) + \epsilon} \]

if \(|y_2| \leq |y_3| \leq \cdots \leq |y_k|\).

Now we discuss gluing of the local models. Let \( X = \mathbb{P}^{n+1}_C \) equipped with the standard complex structure \( J_X \), the Kähler form \( \omega_X \) and the anticanonical bundle \( \omega_X = K_X^{-1} = \mathcal{O}(n+2) \) as in Section 3. For \( \sigma_{X,\infty} = x_1 \cdots x_{n+2} \) and a generic section \( \sigma_{X,0} \in H^0(\mathbb{P}^{n+1}_C, \mathcal{O}(n+2)) \), we consider a pencil of Calabi–Yau hypersurfaces defined by

\( X_z = \{ \sigma_{X,0} - z \sigma_{X,\infty} = 0 \} = p_X^{-1}(1/z) \),

where \( p_X = \sigma_{X,\infty}/\sigma_{X,0} \). Let \( C_i = \{ x_i = 0 \} \cong \mathbb{P}^n_C \), \( i = 1, \ldots, n+2 \) be the irreducible components of \( X_\infty \) and set \( C_0 = X_0 \). We assume that \( \sigma_{X,0} \) is generic so that the divisor \( X_0 \cup X_\infty \) is normal crossing. For \( I \subset \{ 0, 1, \ldots, n+2 \} \), we write \( C_I = \cap_{i \in I} C_i \) and \( C_I^0 = C_I \setminus \bigcup_{J \supset I} C_J \). We will deform \( \omega_X \) in such a way that it satisfies Assumption 4.1 (resp. Assumption 4.3) near \( C_I \) with \( 0 \not\in I \) (resp. \( 0 \in I \)).

**Proposition 4.9** For each \( I \), there exists a tubular neighborhood \( U_I \) of \( C_I \) in \( \mathbb{P}^{n+1}_C \) and a fibration structure \( \pi_I : U_I \to C_I \) such that for each \( p \in C_I \) the tangent space \( T_p \pi_I^{-1}(p) \) of the fiber is a complex subspace in \( T_p X \). Moreover \( \pi_I \) and \( \pi_J \) are compatible if \( I \subset J \).

See Ruan [15, Proposition 7.1] for the definition of the compatibility. This proposition is a weaker version of [15, Proposition 7.1] in the sense that each fiber \( \pi_I^{-1}(p) \) is required to be holomorphic only at \( p \in C_I \).

**Proof** For each \( I \) we take a tubular neighborhood \( U_I \) of \( C_I \), and consider an open covering \( \{ V_\alpha \}_{\alpha \in \mathcal{A}} \) of \( \bigcup_I U_I \) satisfying

- for each \( \alpha \in \mathcal{A} \), there exists a unique subset \( I_\alpha \) in \( \{ 0, 1, \ldots, n+1 \} \) such that
  \( V_\alpha \cap C_{I_\alpha} \neq \emptyset \) and \( V_\alpha \cap C_J = \emptyset \) for all \( J \) with \( |J| > |I_\alpha| \).
We take holomorphic coordinates \((w_\alpha, z_\alpha) = (w_\alpha^1, \ldots, w_\alpha^{n+1-|I_\alpha|}, z_\alpha^1, \ldots, z_\alpha^{|I_\alpha|})\) on \(V_\alpha\) such that \(C_{I_\alpha}\) is given by \(z_\alpha = 0\) and \(w_\alpha\) gives a coordinate on \(C_{I_\alpha} \cap V_\alpha\), and satisfying the following property: the projection \(\pi_\alpha: V_\alpha \rightarrow C_{I_\alpha}\), \((w_\alpha, z_\alpha) \mapsto w_\alpha\) is compatible with \(\pi_J\) for each \(J \supset I_\alpha\). Let \(\{\rho_\alpha\}_{\alpha \in A}\) be a partition of unity associated to \(\{V_\alpha\}\).

Fix \(p \in C_I^0\), and set \(A_p := \{\alpha \in A \mid p \in V_\alpha\}\). Note that \(I_\alpha \supset I\) for any \(\alpha \in A_p\). Take \(\alpha_0 \in A\) such that \(V_{\alpha_0} \cap V_\alpha \neq \emptyset\) for \(\alpha \in A_p\) and \(I_{\alpha_0} = J_\alpha\) is maximal. Rename the coordinates on \(V_\alpha, \alpha \in A_p\) so that the projection \(\pi'_\alpha: V_\alpha \rightarrow C_I\) is given by \((w'_\alpha, z'_\alpha) \mapsto w'_\alpha\). Let

\[
\text{pr}: TV_{\alpha_0}|_{C_I} = \text{span}_\mathbb{C} \left\{ \frac{\partial}{\partial w'^j_0}, \frac{\partial}{\partial z'^j_0} \right\} \oplus \text{span}_\mathbb{C} \left\{ \frac{\partial}{\partial z'^j_0} \right\} \longrightarrow \text{Ker } d\pi'_\alpha = \text{span}_\mathbb{C} \left\{ \frac{\partial}{\partial z'^j_0} \right\}
\]

be the projection. After a coordinate change which is linear in \(z'_\alpha\), we assume that \(\text{pr}(\partial/\partial z'^j_0) = \partial/\partial z'^j_0\) for each \(j\). Define

\[
E_{I,p} = \text{span}_\mathbb{C} \left\{ \sum_{\alpha} \rho_\alpha(p) \frac{\partial}{\partial z'^j_0} \mid j = 1, \ldots, |I| \right\}.
\]

Then \(E_I = \bigcup_{p \in C_I} E_{I,p} \subset TX|_{C_I}\) is a complex subbundle which gives a splitting of \(TX|_{C_I} \rightarrow N_{C_I/X} = TX|_{C_I} / TC_I\). After shrinking \(U_I\) if necessary, we obtain a fibration \(\pi_I: U_I \rightarrow C_I\) such that \(T_p\pi_I^{-1}(p) = E_{I,p}\).

Set \(U_I^0 = \pi_I^{-1}(C_I^0)\). We prove a weaker version of [15, Theorem 7.1].

**Proposition 4.10** There exists a Kähler form \(\omega'_X\) in the class \([\omega_X]\) such that

1. it tames \(J_X\), and compatible with \(J_X\) on \(\bigcup_I C_I\),
2. \(\omega'_X = \omega_X\) outside a neighborhood of \(\text{Sing}(X_0 \cup X_\infty) = \bigcup_{|I| \geq 2} C_I\),
3. \(C_I's\) intersect orthogonally, and
4. each fiber of \(\pi_I: U_I \rightarrow C_I\) is orthogonal to \(C_I\).

**Proof** It is shown by Seidel [17, Lemma 1.7] and Ruan [15, Lemma 4.3] that \(\omega_X\) can be modified locally so that it is standard near the lowest dimensional stratum \(\bigcup_{|I| = n+1} C_I\). We deform the symplectic form inductively to obtain \(\omega'_X\).
Fix $I \subset \{0, 1, \ldots, n+1\}$ and take a distance function $r: X \to \mathbb{R}_{\geq 0}$ from $C_I$, i.e., $C_I = r^{-1}(0)$. Fix a local trivialization of $\omega_X|U_I$ by a section which has unit pointwise norm and parallel in the radial direction of the fibers of $\pi_I$, and let $\theta_X$ denote the connection $1$–form. Then we have $\theta_X - \pi_I^*\left(\theta_X|_TC_I\right) = O(r)$.

Let $\pi: NC_I \to C_I$ be the symplectic normal bundle, i.e., $N_pC_I \subset T_pX$ is the orthogonal complement of $T_pC_I$ with respect to the symplectic form. Let $\omega_N$ be the induced symplectic form on the fibers of $NC_I$. From the symplectic neighborhood theorem, a neighborhood of $C_I$ is symplectomorphic to a neighborhood of the zero section of $NC_I$ equipped with the symplectic form $\pi^*(\omega_X|_{C_I}) + \omega_N$. Identifying $NC_I$ with $E_I$, we obtain a symplectic form $\omega_{U_I}$ on $U_I$ satisfying (i) and (iv). Note that $\omega_{U_I}$ and $\omega_X$ coincide only on $T_C I$ in general. Let $\theta_{U_I}$ be a connection $1$–form on $\omega_{U_I}$ such that $d\theta_{U_I} = \omega_{U_I}$ and $\theta_{U_I}|_{TC_I} = \theta_X|_{TC_I}$. We define $\eta = \theta_X - \theta_{U_I}$. Then $\eta = 0$ on $C_I$. Fix a constant $\delta > 0$ such that $\{r \leq \delta\} \subset U_I$ and take $C > 0$ satisfying

\[
\begin{align*}
C^{-1}\omega_X & \leq t\omega_{U_I} + (1-t)\omega_X \leq C\omega_X, \\
\|\eta\| & \leq Cr, \\
\|dr\| & \leq C
\end{align*}
\]

on $\{r \leq \delta\}$. Let $h: \mathbb{R} \to \mathbb{R}_{\geq 0}$ be a smooth function satisfying

- $\lim_{s \to -\infty} h(s) = 1$,
- $h(s) = 0$ for $s \geq \log \delta$, and
- $-1/(2C^3) \leq h'(s) \leq 0$,

and set $f = h(\log r)$. We define

$$\theta' = \theta_X - f\eta = f\theta_{U_I} + (1-f)\theta_X$$

and

$$\omega' := d\theta' = f\omega_{U_I} + (1-f)\omega_X - df \wedge \eta$$

$$= f\omega_{U_I} + (1-f)\omega_X - h'dr \wedge \frac{\eta}{r}.$$

Then $\omega'$ is compatible with $J_X$ along $C_I$ and the fibers of $\pi_I$ intersect $C_I$ orthogonally. From the choice of $h$, we have

$$\|df \wedge \eta\| \leq \frac{1}{2C^3} \cdot C \cdot C = \frac{1}{2C},$$

which implies that $\omega'$ tames $J_X$, and hence it is non-degenerate.
By applying the argument in Seidel [17, Lemma 1.7] or Ruan [15, Lemma 4.3] to each fiber of \( \pi_I \), we can modify \( \omega' \) to make \( \omega'|_{\pi_I^{-1}(p)} \) standard at each \( p \in C_I \), which means that \( C_J \)'s intersect orthogonally along \( C_I \). \( \square \)

Next we construct local torus actions. Set \( L_i = \mathcal{O}(1) = \mathcal{O}(C_i) \) for \( i = 1, \ldots, n + 2 \) and \( L_0 = \mathcal{O}(n + 2) = \mathcal{O}(C_0) \). Note that the normal bundle of \( C_I \) is given by

\[
\mathcal{N}_C/I \times \bigoplus_{i \in I} L_i|_{C_i}.
\]

For each \( I = \{i_1 < \cdots < i_k\} \subset \{0, 1, \ldots, n + 2\} \), we define a \( T^k \)-action on \( U_I^\circ \) as follows. First we consider the case \( 0 \notin I \). We may assume \( (\prod_{j \notin I \cup \{0\}} x_j)/\sigma_{X,0} \neq 0 \) on \( U_I^\circ \) (after making \( U_I \) smaller if necessary). Then

\[
\bigotimes_{j \notin I \cup \{0\}} \frac{x_j}{\sigma_{X,0}}: L_{i_k}|_{U_I^\circ} \to L_{i_k} \otimes L_0^{-1} \otimes \bigotimes_{j \notin I \cup \{0\}} L_j \bigg|_{U_I^\circ} \cong \mathcal{O}(1 - k)|_{U_I^\circ}
\]

is an isomorphism, and thus we have

\[
\mathcal{N}_C/I \times |C_I^\circ \cong \mathcal{N}_I|_{C_I^\circ},
\]

where

\[
\mathcal{N}_I := \mathcal{L}_{i_1} \oplus \cdots \oplus \mathcal{L}_{i_k - 1} \oplus \left( \mathcal{L}_{i_k} \otimes \mathcal{L}_0^{-1} \otimes \bigotimes_{j \notin I \cup \{0\}} \mathcal{L}_j \right)
\]

\[
\cong \mathcal{O}(1) \oplus \cdots \oplus \mathcal{O}(1) \oplus \mathcal{O}(1 - k).
\]

We identify \( U_I^\circ \) with a neighborhood of the zero section of \( \mathcal{N}_I|_{C_I^\circ} \) by a map \( \nu_I: U_I^\circ \to \mathcal{N}_I|_{C_I^\circ} \) obtained by combining

\[
\left( x_{i_1}, \ldots, x_{i_{k-1}}, \frac{x_{i_k} \prod_{j \notin I \cup \{0\}} x_j}{\sigma_{X,0}} \right): U_I^\circ \to \mathcal{N}_I
\]

with parallel transport along the fibers of \( \pi_I: U_I^\circ \to C_I^\circ \). The torus action on \( U_I^\circ \) is defined to be the pull back the natural \( T^k \)-action on \( \mathcal{N}_I|_{C_I^\circ} \). By construction,

\[
U_I^\circ \xrightarrow{\nu_I} \mathcal{N}_I|_{C_I^\circ}
\]

\[
\xrightarrow{px} \mathbb{C}
\]

\[\text{(7)}\]
is commutative, where the right arrow is the natural map

\[ N_I = \mathcal{O}(1) \oplus \cdots \oplus \mathcal{O}(1) \oplus \mathcal{O}(1 - k) \longrightarrow \mathbb{C}, \quad (\zeta_1, \ldots, \zeta_k) \mapsto \zeta_1 \cdots \zeta_k. \]

Hence \( p_X = \sigma_{X,\infty}/\sigma_{X,0} \) is \( T^k \)-equivalent on \( U^0_I \):

\[ p_X(\rho_{I,s}(x)) = e^{\sqrt{-1}(s_1 + \cdots + s_k)} p_X(x). \]

Next we consider the case where \( i_1 = 0 \in I \). In this case we set

\[ N_I := \mathcal{L}_{i_1} \oplus \cdots \oplus \mathcal{L}_{i_{k-1}} \oplus \left( \mathcal{L}_{i_k} \bigotimes_{j \notin I} \mathcal{L}_j \right) \]

\[ \cong \mathcal{O}(n + 2) \oplus \mathcal{O}(1) \oplus \cdots \oplus \mathcal{O}(1) \oplus \mathcal{O}(n + 4 - k). \]

Assuming \( \prod_{j \notin I} x_j \neq 0 \) on \( U^0_I \), we have an isomorphism

\[ \bigoplus_{i \in I} \mathcal{L}_i|_{U^0_I} \longrightarrow N_I|_{U^0_I}. \]

By using

\[ \left( \sigma_{X,0}, x_1, \ldots, x_{i_k - 1}, x_k \prod_{j \notin I} x_j \right): U^0_I \longrightarrow N_I, \]

we have a map \( \nu_I: U^0_I \rightarrow N_I|_{U^0_I} \) identifying \( U^0_I \) with a neighborhood the zero section, which gives a \( T^k \)-action on \( U^0_I \) as above. We also have a similar commutative diagram (7) where the right arrow in this case is

\[ \mathcal{O}(n + 2) \oplus \mathcal{O}(1) \oplus \cdots \oplus \mathcal{O}(1) \oplus \mathcal{O}(n + 4 - k) \longrightarrow \mathbb{C}, \quad (\zeta_1, \ldots, \zeta_k) \mapsto \frac{\zeta_2 \cdots \zeta_k}{\zeta_1}. \]

This means that \( p_X \) is \( T^k \)-equivariant on \( U^0_I \):

\[ p_X(\rho_{I,s}(x)) = e^{\sqrt{-1}(-s_1 + s_2 + \cdots + s_k)} p_X(x). \]

We can easily check the compatibility of the above torus actions. For example, we consider the case where \( I = \{0, 1, \ldots, k - 1\} \supset J = \{1, \ldots, l\} \). Take coordinates \((w_1, \ldots, w_{n+1})\) around a point in \( C_I \) such that \((w_1, \ldots, w_k)\) gives fiber coordinates of \( \pi_I \) corresponding to

\[ (\sigma_{X,0}, x_1, \ldots, x_{k-2}, x_{k-1} \cdots x_{n+2}): U_I \rightarrow N_I. \]

Then the torus action is given by

\[ (w_1, \ldots, w_n) \mapsto \left( e^{\sqrt{-1}s_1} w_1, \ldots, e^{\sqrt{-1}s_k} w_k, w_{k+1}, \ldots, w_{n+1} \right). \]
On the other hand, since \( \nu_f: U_f^\circ \to N_f \mid C_f^\circ \) is obtained from
\[
\left( x_1, \ldots, x_{l-1}, x_l \ldots x_{n+2} \right): U_f^\circ \to N_f,
\]
\( \nu_f \) restricted to \( U_f^I \cap U_f^\circ \subset U_f^\circ \) is given by
\[
\nu_f(w_1, \ldots, w_{n+1}) = \left( w_2, \ldots, w_l, \frac{w_{l+1} \ldots w_k}{w_1} \right).
\]
This means that the torus action induced from \( \rho_f \) is given by
\[
(w_1, \ldots, w_{n+1}) \mapsto (w_1, e^{\sqrt{-1}s_2}w_2, \ldots, e^{\sqrt{-1}s_{l+1}}w_{l+1}, w_{l+2}, \ldots, w_{n+1}).
\]
(Note that \( (w_1, w_{l+2}, \ldots, w_{n+1}) \) is a coordinate on the base \( C_f \cap U_f \).) Other cases can be checked in similar ways.

By using the same argument as in Seidel [16, Lemma 7.20], we have

**Proposition 4.11** There exists a Kähler form \( \omega''_X \) in the class \([\omega_X]\) satisfying the conditions in Proposition 4.10, and \( \omega''_X \mid U_f^\circ \) is invariant under the torus action \( \rho_f \) for each \( I \).

We fix \( x \in C_f^\circ \) with \(|I| = k\) and take a neighborhood \( U_x \subset U_f^\circ \) of \( x \). Let \( Y \subset \mathbb{C}^{n+1} \) be a small ball around the origin with the standard symplectic structure \( \omega_Y \) and the \( T^k \)-action (4). Take a \( T^k \)-equivariant Darboux coordinate \( \varphi: (U_x, \omega''_X) \to (Y, \omega_Y) \), and define \( J_Y = (\varphi^{-1})^* J_X \), \( p = (\varphi^{-1})^* p_X \), \( \eta_Y = C(\varphi^{-1})^* \sigma_X^{-1} \), where \( C \) is a constant. Then \((Y, \omega_Y, J_Y, \eta_Y, p)\) satisfies Assumption 4.1 if \( 0 \notin I \), or Assumption 4.3 if \( 0 \in I \) for a suitable choice of \( C \). Now we can follow the argument of [16, Proposition 7.22] to complete the proof of Proposition 3.4.

5 Sheridan’s Lagrangian as a vanishing cycle

An \( n \)-dimensional pair of pants is defined by
\[
\mathcal{P}_n = \{[z_1: \cdots: z_{n+2}] \in \mathbb{P}_{\mathbb{C}}^{n+1} \mid z_1 + \cdots + z_{n+2} = 0, \ z_i \neq 0, \ i = 1, \ldots, n+2 \},
\]
equipped with the restriction of the Fubini–Study Kähler form on \( \mathbb{P}_{\mathbb{C}}^{n+1} \). It is the intersection of the hyperplane \( H = \{z_1 + \cdots + z_{n+2} = 0\} \) with the big torus \( T \) of \( \mathbb{P}_{\mathbb{C}}^{n+1} \). Sheridan [23] perturbs the standard double cover \( S^n \to H_{\mathbb{R}} \) of the real projective space \( H_{\mathbb{R}} \cong \mathbb{P}_{\mathbb{R}}^n \) by the \( n \)-sphere slightly to obtain an exact Lagrangian immersion.
The pull-back of Sheridan’s Lagrangian immersion by \( p \) is given by \( U_K \) parametrized by proper subsets \( K \subseteq \{1, 2, \ldots, n+2\} \) as

\[
U_K = \{ [z_1 : \cdots : z_{n+2}] \in \mathcal{P}^{n+1} \cap H_{\mathbb{R}} | z_i/z_j < 0 \text{ if and only if } i \in K \text{ and } j \in K^c \}.
\]

Note that the set \( \{1, \ldots, n+2\} \) has \( 2^{n+2} - 2 \) proper subsets, and one has \( U_K = U_{K^c} \). The inverse images of the connected component \( H \) of \( p \) induced by \( U_K \) by the double cover \( S^n \to H_{\mathbb{R}} \) are the cells \( W_K, K^c \) and \( W_{K^c, K} \) of the dual cellular decomposition in [23, Definition 2.6].

The map \( p_{\mathcal{M}} : \mathcal{M} \to T \) sending \((u_1, \ldots, u_{n+1}, u_{n+2} = 1/u_1 \cdots u_{n+1})\) to \([z_1 : \cdots : z_{n+1} : 1]\) for \( z_i = u_i \cdot u_1 \cdots u_{n+1} \), \( i = 1, \ldots, n+1 \) is a principal \( \Gamma^{n+2} \)-bundle, where the action of \( \zeta \cdot \text{id}_{\mathcal{C}^{n+2}} \in \Gamma^{n+2} \) sends \((u_1, \ldots, u_{n+2})\) to \((\zeta u_1, \ldots, \zeta u_{n+2})\). The inverse map is given by \( u_1^{n+2} = z_1^{1/n+1} / z_2 \cdots z_{n+1} \) and \( u_i = u_1 \cdot z_i / z_1 \) for \( i = 2, \ldots, n+1 \).

The restriction \( p_{\mathcal{M}_0} : \mathcal{M}_0 \to \mathcal{P}^n \) turns \( \mathcal{M}_0 \) into a principal \( \Gamma^{n+2} \)-bundle over the pair of pants. One has

\[
z_1 = -(1 + z_2 + \cdots + z_{n+1})
\]
on \( \mathcal{P}^n \), so that \( u_1^{n+2} = (-1)^{n+1} f(z_2, \ldots, z_{n+1}) \) where

\[
f(z_2, \ldots, z_{n+1}) = \frac{(1 + z_2 + \cdots + z_{n+1})^{n+1}}{z_2 \cdots z_{n+1}}.
\]

The pull-back of Sheridan’s Lagrangian immersion by \( p_{\mathcal{M}_0} \) is the union of \( n+2 \) embedded Lagrangian spheres \( \{L_i\}_{i=1}^{n+2} \) in \( \mathcal{M}_0 \).

Recall that the coamoeba of a subset of a torus \( (\mathbb{C}^\times)^{n+1} \) is its image by the argument map \( \text{Arg} : (\mathbb{C}^\times)^{n+1} \to \mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1} \). Let \( Z \) be the zonotope in \( \mathbb{R}^{n+1} \) defined as the Minkowski sum of \( \pi e_1, \ldots, \pi e_{n+1}, -\pi e_1 - \cdots - \pi e_{n+1} \), where \( \{e_i\}_{i=1}^{n+1} \) is the standard basis of \( \mathbb{R}^{n+1} \). The projection \( \overline{Z} \) of \( Z \) to \( \mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1} \) is the closure of the complement \( (\mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1}) \setminus \text{Arg}(\mathcal{P}^n) \) of the coamoeba of the pair of pants [23, Proposition 2.1], and the argument projection of the immersed Lagrangian sphere is close to the boundary of the zonotope by construction [23, Section 2.2]. The coamoeba of \( \mathcal{M}_0 \) and the projections of Lagrangian spheres \( L_i \) are obtained from those for \( \mathcal{P}^n \) as the pull-back by the \((n+2)\)-fold cover

\[
\mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1} \to \mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1}
\]

\[
\psi \quad \psi
\]

\[
e_i \quad \mapsto \quad e_i + \sum_{j=1}^{n+1} e_j
\]

induced by \( p_{\mathcal{M}} : \mathcal{M} \to T \). It is elementary to see that none of the pull-backs of the zonotope \( \overline{Z} \) by the map (9) has self-intersections. It follows that the argument projection of \( L_i \) does not have self-intersections either, which in turn implies that \( L_i \) itself does not
have self-intersections, so that $L_i$ is not only immersed but embedded. We choose the numbering on these embedded Lagrangian spheres so that the argument projection of $L_i$ is close to the boundary of the zonotope centered at $\left[\frac{2\pi}{n+2}(i, \ldots, i)\right] \in \mathbb{R}^{n+1} / 2\pi \mathbb{Z}^{n+1}$.

When $n = 1$, the coamoeba of $\overline{M}_0$ is the union of the interiors and the vertices of six triangles shown in Figure 2(a). The projection of $L_3$ is also shown as a solid loop in Figure 2(a). The zonotope $\overline{Z}$ in this case is a hexagon, whose pull-backs by the three-to-one map (9) are three hexagons constituting the complement of the coamoeba. Although the zonotope $\overline{Z}$ has self-intersections at its vertices, none of its pull-backs has self-intersections as seen in Figure 2(a). The coamoeba of $\overline{M}_0$ for $n = 2$ is a four-fold cover of the coamoeba of $\mathcal{P}^2$ shown in [23, Figure 2(b)].

![Figure 2: (a) The coamoeba (b) The cut and the thimble](image)

Let $\overline{\sigma}: \overline{M}_0 \to \mathbb{C}^\times$ be the projection sending $(u_1, \ldots, u_{n+2})$ to $u_1$.

**Lemma 5.1** The critical values of $\overline{\sigma}$ are given by $(n + 2)$ solutions to the equation

$$u_1^{n+2} = (-1)^{n+1}(n + 1)^{n+1}.$$  

**Proof** The defining equation of $\overline{M}_0$ in $\overline{M} = \text{Spec} \mathbb{C}[u_1^{\pm 1}, \ldots, u_{n+1}^{\pm 1}]$ is given by

$$\sum_{i=1}^{n+1} u_i \cdot u_1 \cdots u_{n+1} + 1 = 0. \tag{11}$$

By equating the partial derivatives by $u_2, \ldots, u_{n+1}$ with zero, one obtains the linear equations

$$u_i + \sum_{j=1}^{n+1} u_j = 0, \quad i = 2, \ldots, n + 1,$$

whose solution is given by $u_2 = \cdots = u_{n+1} = -u_1/(n + 1)$. By substituting this into (11), one obtains the desired equation (10). \qed
Homological mirror symmetry for the quintic 3–fold

Note that the connected component

\[ U_1 = U_{\{2, \ldots, n+2\}} = \{[z_1 : z_2 : \cdots : z_{n+1} : 1] \in \mathcal{P}^n \mid (z_2, \ldots, z_{n+1}) \in (\mathbb{R}^{>0})^n\} \]

of the real part of the pair of pants can naturally be identified with \((\mathbb{R}^{>0})^n\).

**Lemma 5.2** The function

\[ f(z_2, \ldots, z_{n+1}) = \frac{(1 + z_2 + \cdots + z_{n+1})^{n+1}}{z_2 \cdots z_{n+1}} \]

has a unique non-degenerate critical point in \(U_1 \cong (\mathbb{R}^{>0})^n\) with the critical value \((n + 1)^{n+1}\).

**Proof** The partial derivatives are given by

\[ \frac{\partial f}{\partial z_2} = ((n + 1)z_2 - (1 + z_2 + \cdots + z_{n+1}))(1 + z_2 + \cdots + z_{n+1})^n \frac{z_2^2 \cdots z_{n+1}}{z_2 \cdots z_{n+1}} \]

and similarly for \(z_3, \ldots, z_{n+1}\). By equating them with zero, one obtains the equations

\[(n + 1)z_i - (1 + z_2 + \cdots + z_{n+1}) = 1, \quad i = 2, \ldots, n + 1\]

whose solution is given by \(z_2 = \cdots = z_{n+1} = 1\) with the critical value \((n + 1)^{n+1}\). \(\square\)

As an immediate corollary, one has:

**Corollary 5.3** The inverse image of \(f: U_1 \to \mathbb{R}\) at \(t \in \mathbb{R}\) is

- empty if \(t < (n + 1)^{n+1}\),
- one point if \(t = (n + 1)^{n+1}\), and
- diffeomorphic to \(S^{n-1}\) if \(t > (n + 1)^{n+1}\).

Recall that \(f\) is introduced in (8) to study the inverse image of the map \(p: \widetilde{M}_0 \to \mathcal{P}^n\).

**Corollary 5.4** The inverse image \(p^{-1}(U_1)\) consists of \(n + 2\) connected components \(U_\zeta\) indexed by solutions to the equation \(\zeta^{n+2} = (-1)^{n+1}(n + 1)^{n+1}\) by the condition that \(\zeta \in \mathcal{O}(U_\zeta)\).

One obtains an explicit description of Lefschetz thimbles:

**Lemma 5.5** \(U_\zeta\) is the Lefschetz thimble for \(\mathcal{O}: \widetilde{M}_0 \to \mathbb{C}^\times\) above the half line \(\ell: [0, \infty) \to \mathbb{C}^\times\) on the \(x_1\)–plane given by \(\ell(t) = t\zeta + \zeta\).
The following simple lemma is a key to the proof of Proposition 3.1:

**Proof** The restriction of \( \varpi \) to \( U_\zeta \) has a unique critical point at \((x_1, \ldots, x_{n+1}) = \frac{\zeta}{n+1}(n + 1, -1, \ldots, -1)\). For \( x = (x_1, \ldots, x_{n+1}) \in U_\zeta \) outside the critical point, the fiber \( \mathcal{V}_{x_1} = U_\zeta \cap \varpi^{-1}(x_1) \) is diffeomorphic to \( S^{n-1} \) by Corollary 5.3, and it suffices to show that the orthogonal complement of \( T_x \mathcal{V}_{x_1} \) in \( T_x U_\zeta \) is orthogonal to \( T_x \varpi^{-1}(x_1) \) with respect to the Kähler metric \( g \) of \( \widetilde{M}_0 \). Let \( X \in T_x U_\zeta \) be a tangent vector orthogonal to \( T_x \mathcal{V}_{x_1} \). Then it is also orthogonal to \( T_x \varpi^{-1}(x_1) \) since any element in \( T_x \varpi^{-1}(x_1) \) can be written as \( zY \) for \( z \in \mathbb{C} \) and \( Y \in T_x \mathcal{V}_{x_1} \), so that \( g(zY, X) = zg(Y, X) = 0 \). \( \square \)

The following simple lemma is a key to the proof of Proposition 3.1:

**Lemma 5.6** \( U_\zeta \) for \( \arg \zeta \neq \pm \frac{n+1}{n+2} \pi \) does not intersect \( L_{n+2} \).

**Proof** The map \( \mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1} \to \mathbb{R}^{n+1}/2\pi \mathbb{Z}^{n+1} \) induced from the map \( p: \widetilde{M} \to T \) is given on coordinate vectors by \( e_i \mapsto e_i + \sum_{j=1}^{n+1} e_j \). The inverse map is given by \( e_i \mapsto f_i = e_i - \frac{1}{n+2} \sum_{j=1}^{n+1} e_j \), so that the argument projection of \( L_{n+2} \) is close to the boundary of the zonotope \( Z_{n+2} \) generated by \( \pi f_1, \ldots, \pi f_{n+1}, -\pi f_1, \ldots, -\pi f_{n+1} \). The argument projection of \( U_\zeta \) consists of just one point \((\arg(\zeta), \arg(\zeta) + \pi, \ldots, \arg(\zeta) + \pi)\), which is disjoint from \( Z_{n+2} \) if \( \arg \zeta \neq \pm \frac{n+1}{n+2} \pi \). \( \square \)

The \( n = 1 \) case is shown in Figure 2(b). Black dots are images of \( U_\zeta \) for \( \zeta = \frac{1}{\sqrt{4}}, \frac{3}{\sqrt{4}} \exp(2\pi \sqrt{-1}/3), \frac{7}{\sqrt{4}} \exp(4\pi \sqrt{-1}/3) \), and white dots are images of \( \widetilde{M}_0 \setminus E \) defined below. One can see that \( L_3 \) is contained in \( E \) and disjoint from \( U_{\frac{1}{\sqrt{4}}} \).

Now we use symplectic Picard–Lefschetz theory developed by Seidel [20]. Put \( S = \mathbb{C}^\times \setminus (-\infty, 0) \) and let \( E = \varpi^{-1}(S) \) be an open submanifold of \( \widetilde{M}_0 \). Note that both \( V_{n+2} \) and \( L_{n+2} \) are contained in \( E \). The restriction \( \varpi_E: E \to S \) of \( \varpi \) to \( E \) is an exact symplectic Lefschetz fibration, in the sense that all the critical points are non-degenerate with distinct critical values. Although \( \varpi_E \) does not fit in the framework of Seidel [20, Section III] where the total space of a fibration is assumed to be a compact manifold with corners, one can apply the whole machinery of [20] by using the tameness of \( \varpi_E \) (i.e., the gradient of \( \|\varpi_E\| \) is bounded from below outside of a compact set by a positive number) as in Seidel [21, Section 6]. Let \( \mathcal{F}(\varpi_E) \) be the Fukaya category of the Lefschetz fibration in the sense of Seidel [20, Definition 18.12]. It is the \( \mathbb{Z}/2\mathbb{Z} \)-invariant part of the Fukaya category of the double cover \( \widetilde{E} \to E \) branched along \( \varpi_E^{-1}(\ast) \), where \( \ast \in S \) is a regular value of \( \varpi_E \). Different base points \( \ast \in S \) lead to symplectomorphic double covers, so that the quasi-equivalence class of \( \mathcal{F}(\varpi_E) \) is independent of this choice. We choose \( \ast \) to be a sufficiently large real number. Let \((y_1, \ldots, y_{n+2})\) be a distinguished set of vanishing paths chosen as in
Figure 3(a). The pull-backs of the corresponding Lefschetz thimbles in \( E \) by the double cover \( \tilde{E} \to E \) will be denoted by \((\tilde{\Delta}_1, \ldots, \tilde{\Delta}_{n+2})\), which are called type (B) Lagrangian submanifolds by Seidel [20, Section 18a]. On the other hand, the pull-back of a closed Lagrangian submanifold of \( E \), which is disjoint from the branch locus, is a Lagrangian submanifold of \( \tilde{E} \) consisting of two copies of the original Lagrangian submanifold. It also gives rise to an object of \( \mathcal{F}(\pi_E) \), which is called a type (U) Lagrangian submanifold by Seidel. The letters (B) and (U) stand for ‘branched’ and ‘unbranched’ respectively.

**Theorem 5.7** (Seidel [20, Propositions 18.13, 18.14, and 18.17])

- \((\tilde{\Delta}_1, \ldots, \tilde{\Delta}_{n+2})\) is an exceptional collection in \( \mathcal{F}(\pi_E) \).
- There is a cohomologically full and faithful \( A_\infty \)-functor \( \mathcal{F}(E) \to \mathcal{F}(\pi_E) \).
- The essential image of \( \mathcal{F}(E) \) is contained in the full triangulated subcategory generated by \((\tilde{\Delta}_1, \ldots, \tilde{\Delta}_{n+2})\).

We abuse the notation and use the same symbol \( L_{n+2} \) for the corresponding object in \( \mathcal{F}(\pi_E) \). The following lemma is a consequence of Lemma 5.6:

**Lemma 5.8** One has \( \text{Hom}^*_E(\tilde{\Delta}_i, L_{n+2}) = 0 \) for \( i \neq 1, n+2 \).

**Proof** For \( 2 \leq i \leq n+1 \), move \( * \in S \) continuously from the positive real axis to

\[
*' = \exp[(-n - 3 + 2i)\pi \sqrt{-1}/(n + 2)] \cdot *
\]

and move the distinguished set \((\gamma_1, \ldots, \gamma_{n+2})\) of vanishing paths in Figure 3(a) to \((\gamma'_1, \ldots, \gamma'_{n+2})\) in Figure 3(b) accordingly. The corresponding double covers \( \tilde{E} \) and \( \tilde{E}' \) are related by a Hamiltonian isotopy sending type (B) Lagrangian submanifolds \((\tilde{\Delta}_1, \ldots, \tilde{\Delta}_{n+2})\) of \( \tilde{E} \) to type (B) Lagrangian submanifolds \((\tilde{\Delta}'_1, \ldots, \tilde{\Delta}'_{n+2})\) of \( \tilde{E}' \).

It follows from Lemma 5.6 that the type (U) Lagrangian submanifold of \( E' \) associated with \( L_{n+2} \) does not intersect with \( \tilde{\Delta}'_i \). This shows that \( \text{Hom}^*_E(\tilde{\Delta}'_i, L_{n+2}) = 0 \), which implies \( \text{Hom}^*_E(\tilde{\Delta}_i, L_{n+2}) = 0 \) by Hamiltonian isotopy invariance of the Floer cohomology. \( \square \)

It follows that \( L_{n+2} \) belongs to the triangulated subcategory generated by the exceptional collection \((\tilde{\Delta}_1, \tilde{\Delta}_{n+2})\). Since \( L_{n+2} \) is exact, the Floer cohomology of \( L_{n+2} \) with itself is isomorphic to the classical cohomology of \( L_{n+2} \).

**Lemma 5.9** (Seidel [18, Lemma 7]) Let \( \mathcal{T} \) be a triangulated category with a full exceptional collection \((\mathcal{E}, \mathcal{F})\) such that \( \text{Hom}^*(\mathcal{E}, \mathcal{F}) \cong H^*(S^{n-1}; \mathbb{C}) \), and \( L \) be an object of \( \mathcal{T} \) such that \( \text{Hom}^*(L, L) \cong H^*(S^n; \mathbb{C}) \). Then \( L \) is isomorphic to the mapping cone \( \text{Cone}(\mathcal{E} \to \mathcal{F}) \) over a non-trivial element in \( \text{Hom}^0(\mathcal{E}, \mathcal{F}) \cong \mathbb{C} \) up to shift.
This shows that $L_{n+2}$ is isomorphic to $\text{Cone}(\tilde{\Delta}_1 \to \tilde{\Delta}_{n+2})$ in $D^\pi \mathcal{F}(\varpi_E)$ up to shift. On the other hand, it is shown by Futaki and Ueda [7, Section 5] that $V_{n+2}$ is isomorphic to the matching cycle associated with the matching path $\mu_{n+2}$ shown in Figure 3(c) (see [7, Figure 5.2]). Here, a matching path is a path on the base of a Lefschetz fibration between two critical values, together with additional structures which enables one to construct a Lagrangian sphere (called the matching cycle) in the total space by arranging vanishing cycles along the path (see Seidel [20, Section 16g]). Since the matching path $\mu_{n+2}$ does not intersect $\gamma_i$ for $i \neq 1, n + 2$, the vanishing cycle $V_{n+2}$ is also orthogonal to $\tilde{\Delta}_2, \ldots, \tilde{\Delta}_{n+1}$ in $D^\pi \mathcal{F}(\varpi_E)$. It follows that $L_{n+2}$ equipped with a suitable grading is isomorphic to $V_{n+2}$ in $\mathcal{F}(E)$. Note that any holomorphic disk in $\bar{M}_0$ bounded by $L_{n+2} \cup V_{n+2}$ is contained in $E$, since any such disk projects by $\varpi_E$ to a disk in $S$. This shows that the isomorphism $L_{n+2} \sim V_{n+2}$ in $\mathcal{F}(E)$ extends to an isomorphism in $\mathcal{F}(\bar{M}_0)$, and the following proposition is proved:

**Proposition 5.10** $L_{n+2}$ and $V_{n+2}$ are isomorphic in $\mathcal{F}(\bar{M}_0)$.

Proposition 3.1 follows from Proposition 5.10 by the $\Gamma_{n+2}$ action, which is simply transitive on both $\{V_i\}_{i=1}^{n+2}$ and $\{L_i\}_{i=1}^{n+2}$.

**Remark 5.11** Let $\mathcal{F}^{\rightarrow}$ be the directed subcategory of $\mathcal{F}(M_0)$ consisting of the distinguished basis $(\tilde{V}_i)_{i=1}^{N}$ of vanishing cycles of the exact Lefschetz fibration $\pi_M: M \to \mathbb{C}$;

$$\text{hom}_{\mathcal{F}^{\rightarrow}}(\tilde{V}_i, \tilde{V}_j) = \begin{cases} \mathbb{C} \cdot \text{id}_{\tilde{V}_i} & i = j, \\ \text{hom}_{\mathcal{F}(M_0)}(\tilde{V}_i, \tilde{V}_j) & i < j, \\ 0 & \text{otherwise}. \end{cases}$$

It is also isomorphic to the directed subcategory of $\mathcal{F}(X_0)$, since the compositions $m_2$ are the same on $\mathcal{F}(M_0)$ and $\mathcal{F}(X_0)$, and higher $A_\infty$-operations $m_k$ for $k \geq 3$...
\[ D^b \mathcal{F} \cong D^b \mathcal{F}(\pi_M) \]
with the Fukaya category of the Lefschetz fibration \( \pi_M \). This provides a commutative diagram
\[
\begin{array}{ccc}
\mathcal{F} & \cong & \mathcal{F}_q \\
\downarrow & & \downarrow \\
C_{n+2} \times \Gamma & \cong & \psi^* S_q
\end{array}
\]
of \( A_\infty \)-categories, where horizontal arrows are embeddings of directed subcategories.

Combined with the equivalences
\[
D^b \mathcal{F} \cong D^b \mathcal{F}(\pi_M), \quad D^\pi(\mathcal{F}_q \otimes_{\Lambda_N} \Lambda_Q) \cong D^\pi \mathcal{F}(X_0), \\
D^b \left( C_{n+2} \times \Gamma \right) \cong D^b \text{coh}[\mathbb{P}^n / \Gamma] \quad \text{and} \quad D^\pi(\mathcal{S}_q \otimes_{\Lambda_N} \Lambda_Q) \cong D^b \text{coh} \mathbb{Z}_q^*,
\]
this gives the compatibility of homological mirror symmetry
\[ D^b \mathcal{F}(\pi_M) \cong D^b \text{coh}[\mathbb{P}^n / \Gamma] \]
for the ambient space and homological mirror symmetry
\[ D^\pi \mathcal{F}(X_0) \cong \psi^* D^b \text{coh} \mathbb{Z}_q^* \]
for its Calabi–Yau hypersurface.
