

Pessimal packing shapes

YOAV KALLUS

We address the question of which convex shapes, when packed as densely as possible under certain restrictions, fill the least space and leave the most empty space. In each different dimension and under each different set of restrictions, this question is expected to have a different answer or perhaps no answer at all. As the problem of identifying global minima in most cases appears to be beyond current reach, in this paper we focus on local minima. We review some known results and prove these new results: in two dimensions, the regular heptagon is a local minimum of the double-lattice packing density, and in three dimensions, the directional derivative (in the sense of Minkowski addition) of the double-lattice packing density at the point in the space of shapes corresponding to the ball is in every direction positive.

52A40; 52C15, 52C17

1 Introduction

An n -dimensional convex body is a convex, compact, subset of \mathbb{R}^n with nonempty interior. The space of convex bodies, denoted \mathcal{K}^n , can be endowed with the Hausdorff metric

$$\text{dist}(K, K') = \min\{\varepsilon \mid K' \subseteq K_\varepsilon \text{ and } K \subseteq K'_\varepsilon\},$$

where $K_\varepsilon = \{\mathbf{x} + \mathbf{y} \mid \mathbf{x} \in K, \|\mathbf{y}\| \leq \varepsilon\}$ is the ε -parallel body of K .

A set of isometries Ξ is said to be admissible for K if the interiors of $\xi(K)$ and $\xi'(K)$ are disjoint for all distinct $\xi, \xi' \in \Xi$. The (lower) mean volume of Ξ can be defined as $d(\Xi) = \liminf_{r \rightarrow \infty} (4\pi r^3/3) / |\{\xi \in \Xi \mid \|\xi(0)\| < r\}|$. The collection $\{\xi(K) \mid \xi \in \Xi\}$ for an admissible Ξ is called a packing of K and said to be produced by Ξ . Its density is the fraction of space it fills: $\text{vol}(K)/d(\Xi)$. The packing density of a body K , denoted $\delta(K)$ is the supremum of $\text{vol}(K)/d(\Xi)$ over all admissible sets of isometries. Groemer proves some basic results about packing densities, including the fact that the supremum is actually achieved by some packing and the fact that $\delta(K)$ is continuous [10]. Groemer's result apply also to the restricted packing densities which we define below.

An inversion about a point x is the isometry $I_x: y \mapsto 2x - y$. While the group of isometries of \mathbb{R}^n is not preserved under conjugation by an affine transformation of \mathbb{R}^n , the subgroup made of all translations and inversions about points is invariant. It is interesting to consider packings produced by sets of only translations and inversions. The supremum of $\text{vol}(K)/d(\Xi)$ over packings restricted in this way, denoted $\delta_{T^*}(K)$, is preserved under affine transformations of K and therefore we may say that the domain of $\delta_{T^*}(K)$ is the space of affine equivalence classes of convex bodies. Macbeath showed that this space (with the induced topology) is compact [16], and so δ_{T^*} achieves a global minimum.

Similarly, we may restrict to packings produced only by a set of translations, produced only by the set of elements of a group of translations (namely a Bravais lattice, or simply *lattice* hence), or produced only by the set of elements of a group of translations and inversions (namely a *double lattice*, after G Kuperberg and W Kuperberg [15]), and define respectively $\delta_T(K)$, $\delta_L(K)$ and $\delta_{L^*}(K)$ in the obvious way. By the same argument as for $\delta_{T^*}(K)$, all these functions must also achieve a global minimum. The following problem has been suggested, for example by A Bezdek and W Kuperberg [1] (but see also Brass, Moser and Pach[2]).

Problem 1 *In n dimensions, what are the minima of δ_T , δ_{T^*} , δ_L , and δ_{L^*} ? Which bodies achieve these minima?*

Fáry showed that in two dimensions, triangles are the unique minimum of δ_L [6]; see also Courant [3]. Also, due to a result of L Fejes Tóth, $\delta_L = \delta_T$ in two dimensions, so triangles also minimize δ_T [7]; see also Rogers [20].

A body K is said to be centrally symmetric (cs) if there is a point x such that $I_x(K) = K$. It is reasonable to restrict the functions δ_T and δ_L to the space \mathcal{K}_0^n of cs bodies and ask for the minima of these restricted functions, since these bodies correspond to unit balls in finite-dimensional Banach spaces. Therefore the following question is a natural one to ask.

Problem 2 *In n dimensions, what are the minima of δ_T and δ_L among cs bodies? Which bodies achieve these minima?*

In two dimensions, Reinhardt conjectured that a certain smoothed octagon — a regular octagon whose corners are rounded off by arcs of hyperbolas — minimizes δ_L ; see Reinhardt [19] and Mahler [17]. Due to the same result of L Fejes Tóth, we have that $\delta(K) = \delta_T(K) = \delta_L(K)$ for cs bodies K in two dimensions [7].

By contrast to the functions considered in Problems 1–2, $\delta(K)$ is not invariant under affinities, but only under isometries and dilations. Therefore, its infimum over all bodies

Figure 1: Densest packing structure of pessimal packing shapes: the Reinhardt octagon has a one-parameter family of optimal lattices, each of which fills $0.90241\dots$ of the plane, which is conjectured to be less than is filled by the densest lattice packing of any other shape. The top row shows three examples from this family. The densest lattice packing of triangles (bottom left) fills $\frac{2}{3}$ of the plane and is less dense than the densest lattice packing of any other shape. The densest double-lattice packing of regular heptagons (bottom right) fills $0.89269\dots$ of the plane and is conjectured to be less dense than the densest double-lattice packing of any other shape.

(which is bounded from below by the minimum of $\delta_{\mathcal{T}^*}$) is in theory not necessarily achieved by any particular body. In three dimensions, the claim that the ball is the minimum of $\delta(K)$ has come to be known as Ulam's packing conjecture, due to a remark Gardner attributes to Ulam, though there is no evidence to confirm that Ulam ever stated it as a conjecture [8]. More generally, it is natural to ask the following.

Problem 3 *In n dimensions, what is the infimum of δ ? Is this infimum achieved by some body?*

So far, with the exception of the case of $\delta_{\mathcal{T}}$ and $\delta_{\mathcal{L}}$ in two dimensions and the trivial case of one dimension, none of Problems 1–3 have been solved in any dimension. There are two kinds of partial answers that have been successfully obtained: lower bounds and local minima. In this paper we will focus on the results of the second kind and content ourselves with a few references to results of the first kind; see [15], Smith [23], Ennola [5] and Hlawka [12]. Each of Problems 1–3 lends itself to a local variation: which bodies are a local minimum of the function in question? In two dimensions, Nazarov showed that Reinhardt's smoothed octagon is a local minimum of $\delta_{\mathcal{L}}$ (and therefore also $\delta_{\mathcal{T}}$) among cs bodies [18]. In three dimensions, I showed that the ball is

a local minimum of δ_L among cs bodies [13], and therefore also a local minimum of δ_T and δ among cs bodies, due to Hales’s confirmation of Kepler’s conjecture [11].

In this paper we show that the regular heptagon is a local minimum of δ_{L^*} . Also, failing to show that the three-dimensional ball is a local minimum of δ , we show that the directional derivative at the ball with respect to Minkowski addition is positive in all directions.

2 The regular heptagon

Let K be a two-dimensional convex body (hence, *domain*) of area A . We say that a chord is an affine diameter of K if it is at least as long as all parallel chords, and we call its length the length of K in its direction. We say an inscribed parallelogram is a half-length parallelogram if one pair of sides is half the length of K in the direction parallel to them. G Kuperberg and W Kuperberg have shown that in two dimensions $\delta_{L^*}(K) = A/2\Delta(K)$, where $\Delta(K)$ is the area of the half-length parallelogram of least area inscribed in K [15]. They also show that $\delta_{L^*}(K) \geq \sqrt{3}/2 = 0.86602\dots$ for all domains K [15]. Doheny shows that this bound is not sharp [4]. Here we show that the regular heptagon, for which $\delta_{L^*}(M) = 0.89269\dots$ (exact value below), is a local minimum. It is reasonable to conjecture that this is also a global minimum.

Figure 2: The half-length parallelogram of least area inscribed in the regular heptagon

For definiteness, we fix a regular heptagon M with vertices $m_i = R^i(1, 0)$, $i = 0, \dots, 6$ where R^i is a counterclockwise rotation by $2\pi i/7$ about the origin (we understand the label i to take values in $\mathbb{Z}/7\mathbb{Z}$). The coordinates of the vertices are then in the field extension $\mathbb{Q}(u, v)$, where $u = \cos \pi/7$ and $v = \sin \pi/7$, and we will give all explicit numbers below in the reduced form $a + bu + cu^2 + v(d + eu + fu^2)$. The least-area

half-length parallelogram inscribed in M (see Figure 2) is the rectangle $p_1 p_2 p_3 p_4$, where $p_1 = (1 - a)m_1 + am_2$, $p_2 = (1 - b)m_2 + bm_3$, $p_3 = (1 - b)m_5 + bm_4$, $p_4 = (1 - a)m_6 + am_5$, $a = \frac{7}{4} - 2u^2$ and $b = -\frac{1}{2} + u^2$. As the area of this rectangle is given by $\Delta = (-19 + 2u + 56u^2)v/8$ and the area of the heptagon is given by $A = 7uv$, the double-lattice packing density of M is $A/2\Delta = \frac{2}{97}(-111 + 492u - 356u^2) = 0.89269\dots$. This rectangle is of course one of seven equivalent rectangles $R^i(p_1 p_2 p_3 p_4)$, $i = 0, \dots, 6$.

Let us now consider a different domain M' , with area A' and least-area half-length parallelogram of area Δ' . We will be interested in the limit that M' becomes more and more similar to M . Therefore, let us assume that $(1 - \varepsilon)M \subseteq M' \subseteq (1 + \varepsilon)M$, and we will explore what happens as we let ε approach 0. We wish to prove that there exists $\varepsilon > 0$ such that $A'/2\Delta' \geq A/2\Delta$ for all M' . We will prove this in two steps: we first prove that $A'/2\Delta' \geq A/2\Delta$ if M' is also a heptagon, and then we prove that M' is a heptagon if $A'/2\Delta' \leq A/2\Delta$.

Theorem 1 *There exists $\varepsilon > 0$ such that if M' is a heptagon and $(1 - \varepsilon)M \subseteq M' \subseteq (1 + \varepsilon)M$ then $A'/2\Delta' \geq A/2\Delta$, with equality only when M' is affinely equivalent to M .*

Proof Let the vertices of M' be $m'_i = R^i(1 + x_i, y_i)$, $i = 0, \dots, 6$. Denote by \mathbf{x} the vector $(x_0, y_0, x_1, \dots, x_6, y_6)$ in \mathbb{R}^{14} . By the affine invariance of the double-lattice packing density, we may assume without loss of generality that \mathbf{x} lies, say, in the 8-dimensional subspace $W \subseteq \mathbb{R}^{14}$ consisting of all vectors such that $x_0 = x_2 = x_5 = y_0 = y_2 = y_5 = 0$. Note that $\|\mathbf{x}\| \leq C\varepsilon$ (here and below, we use C and c to denote constants whose exact value is irrelevant to the argument and which may be different from line to line but have no implicit dependence on any variable). We will assume that $A'/2\Delta' \leq A/2\Delta$, and show that we necessarily then have that $M' = M$.

Consider the altitude dropped from each vertex m'_i of M' to the opposite edge $m'_{i+3}m'_{i+4}$ and label the point of intersection k'_i . The chord $m'_i k'_i$ is an affine diameter of M' . Consider also for each i , the two chords parallel to $m'_i k'_i$ but of half its length, and let the parallelogram formed by them be of area Δ_i . Let $\phi_i = (A'/2\Delta_i)/(A/2\Delta) - 1$. By our assumption, $\phi_i \leq 0$ for all i .

Consider ϕ_i as a function of \mathbf{x} . This function depends analytically on \mathbf{x} in a neighborhood of the origin. Within this neighborhood, we may bound $\phi_i(\mathbf{x})$ using its Taylor series

$$\phi_i(\mathbf{x}) \geq \langle \mathbf{f}_i, \mathbf{x} \rangle + \frac{1}{2} \langle \mathbf{x}, F_i \mathbf{x} \rangle - C \|\mathbf{x}\|^3,$$

where the explicit values of \mathbf{f}_i and F_i are given in Tables 1 and 3.

	f_0	u_1	u_2
$\langle \cdot, e_1 \rangle$	$-\frac{2(419-452u+40u^2)}{679}$	0	0

Table 1: The left column gives the elements of f_0 in the standard basis of \mathbb{R}^{14} . The elements of f_i are obtained by a cyclic permutation of the indices by $2i$. The other two columns give the elements of vectors such that $a_1u_1 + a_2u_2$ is the general solution satisfying the equations (1) and $x_0 = x_2 = x_5 = y_0 = y_2 = y_5 = 0$.

We note that there exist coefficients $c_i > 0$ such that $\sum_{i=0}^6 c_i f_i = 0$, namely $c_i = 1$ for all i . It follows from the fundamental theorem of linear algebra that $\langle f_i, x \rangle \leq 0$ for all i if and only if

$$(1) \quad \langle f_i, x \rangle = 0 \quad \text{for all } i.$$

The intersection of the space of solutions to (1) with W is the two-dimensional space spanned by the two vectors given in Table 1. We denote the orthogonal projection to this space as P . Note that (by a compactness argument) $\langle f_i, x \rangle \geq c\|(1 - P)x\|$ for at least one i , and so it follows from the assumption that $\phi_i(x) \leq 0$ for all i and the fact that $\phi_i \geq \langle f_i, x_i \rangle - C\|x\|^2$ that $\|(1 - P)x\| \leq C\|x\|^2$. Therefore we also have that

$$\phi_i(x) \geq \langle f_i, (1 - P)x \rangle + \frac{1}{2}\langle x, PF_iPx \rangle - C\|x\|^3.$$

By direct calculation, we observe that PF_iP is positive definite (when restricted to the image of P) for all i , and so $\frac{1}{2}\langle \mathbf{x}, PF_iP\mathbf{x} \rangle \geq c\|P\mathbf{x}\|^2$. Therefore, $0 \geq \phi_i \geq c\|(1 - P)\mathbf{x}\| + c'\|P\mathbf{x}\|^2 - C\|\mathbf{x}\|^3$ for at least one i , and if ε is small enough then $\mathbf{x} = 0$ necessarily. \square

Theorem 2 *There exists $\varepsilon > 0$ such that if $(1 - \varepsilon)M \subseteq M' \subseteq (1 + \varepsilon)M$ then $A'/2\Delta' \geq A/2\Delta$, with equality only when M' is affinely equivalent to M .*

Proof We now allow M' to be an arbitrary domain, not necessarily a heptagon. Consider the length of M as a function of direction. This function has seven local minima, corresponding to the chords from each vertex \mathbf{m}_i to the midpoint of the opposite edge \mathbf{k}_i . The corresponding function for M' must also, when ε is sufficiently small, have at least seven local minima realized by chords $\mathbf{m}'_i\mathbf{k}'_i$, where $\|\mathbf{m}'_i - \mathbf{m}_i\|, \|\mathbf{k}'_i - \mathbf{k}_i\| < C\varepsilon$ for all i . As in the previous proof, let us denote $\mathbf{m}'_i = R^i(1 + x_i, y_i)$. Additionally, let \mathbf{k}''_i be the nearest point on the chord $\mathbf{m}'_{i+3}\mathbf{m}'_{i+4}$ to the point \mathbf{m}'_i and let $\mathbf{k}'_i = \mathbf{k}''_i + R^i(x'_i, y'_i)$ (see Figure 3).

Figure 3: For a given domain M' in the proof of Theorem 2, we identify directions for which the length of M' is a local minimum. For example, in the illustration $\mathbf{m}'_0\mathbf{k}'_0$ is an affine diameter associated with one of these directions. Other such affine diameters originate at \mathbf{m}'_3 and \mathbf{m}'_4 . To build more directly on the result for nonregular heptagons of Theorem 1, we give the coordinates of (x'_0, y'_0) of \mathbf{k}'_0 in reference to \mathbf{k}''_0 , the point closest to \mathbf{m}'_0 on the chord $\mathbf{m}'_3\mathbf{m}'_4$ (see text).

For each chord $\mathbf{m}'_i\mathbf{m}'_{i+1}$ consider the arc of the boundary between \mathbf{m}'_i and \mathbf{m}'_{i+1} as the graph of a function $h_i(t)$, where $2vh_i(t)$ is the height of the boundary above the chord at the point $(1 - t)\mathbf{m}'_i + t\mathbf{m}'_{i+1}$ on the chord (see Figure 4). Denote the corresponding boundary point $\mathbf{p}_i(t)$. The domain M' is fully specified by the points \mathbf{m}'_i and \mathbf{k}'_i and the functions $h_i(t)$, $i = 0, \dots, 6$. However, we intend to use only the points \mathbf{m}'_i

and k'_i and the values $h_i(a)$, $h_i(b)$, $h_i(1-b)$, and $h_i(1-a)$. Note that given the value of, say, $h_i(t_0)$, we can bound nearby values by convexity:

$$(2) \quad \min\left(\frac{t}{t_0}, \frac{1-t}{1-t_0}\right) \leq \frac{h_i(t)}{h_i(t_0)} \leq \max\left(\frac{t}{t_0}, \frac{1-t}{1-t_0}\right).$$

Figure 4: The arc of the boundary of M' between the points m'_i and m'_{i+1} is given by the graph of the function $h_i(t)$. The highlighted gray area marks the region where the boundary must lie according to (2).

Consider now the two chords parallel to $m'_i k'_i$ and half of its length. It is impossible to determine the distance between them based on only the values we have decided to use. However, we can bound it from above by replacing the actual boundary of M' with the graph of the upper bound given by (2). Specifically, we replace the boundary above $m_{i+1} m_{i+2}$, $m_{i+2} m_{i+3}$, $m_{i+4} m_{i+5}$, and $m_{i+5} m_{i+6}$, respectively with the upper bound given by $t_0 = a, b, (1-b)$ and $(1-a)$. We then find the chords of the replacement boundary arcs that are parallel to $m'_i k'_i$ and half of its length, and call the area of the resulting parallelogram Δ_i . Note that $\Delta_i \geq \Delta'$, since Δ_i is no smaller than the area of an actual half-length parallelogram inscribed in M' , which is in turn no smaller than the smallest such area. Let A'' be the area of the polygon $m'_0 p_0(a) p_0(b) k'_4 p_0(1-b) p_0(1-a) m'_1 \cdots p_6(1-b) p_6(1-a)$, so we have $A'' \leq A'$. We will assume that $A'/2\Delta' \leq A/2\Delta$, and show that this necessarily implies that M' is affinely equivalent to M . Since $A''/2\Delta_i \leq A'/2\Delta'$, then $\phi_i = (A''/2\Delta_i)/(A/2\Delta) - 1 \leq 0$.

Let us consider ϕ_i as a function of $\mathbf{x} = (x_0, y_0, x_1, y_1, \dots, y_6) \in \mathbb{R}^{14}$, and $\mathbf{x}' = (x'_0, y'_0, x'_1, y'_1, \dots, y'_6, h_0(a), h_0(b), h_0(1-b), h_0(1-a), h_1(a), \dots, h_6(1-a)) \in \mathbb{R}^{42}$. In contrast to the last proof, here ϕ_i is not analytic in any neighborhood of the origin in $\mathbb{R}^{14} \times \mathbb{R}^{42}$. However, it does, everywhere in such a neighborhood, take the value of one of 16 analytic functions (let us call them $\phi_{ij}(\mathbf{x}, \mathbf{x}')$, $j = 1, \dots, 16$), based on whether $t > t_0$ or not at the point of contact of the parallelogram with each of the four replacement boundary arcs. When $\mathbf{x}' = 0$ all sixteen functions agree. Also, the first derivatives of ϕ_{ij} with respect to any component taken at the origin are independent of j . Therefore, we have that

$$\phi_i(\mathbf{x}, \mathbf{x}') \geq \phi_i(\mathbf{x}, 0) + \langle \mathbf{f}'_i, \mathbf{x}' \rangle - C \|\mathbf{x}'\|(\|\mathbf{x}\| + \|\mathbf{x}'\|).$$

Note that $\phi_i(\mathbf{x}, 0) \geq (A_0/2\Delta_0)/(A/2\Delta) - 1$, where $A_0/2\Delta_0$ is the double-lattice packing density of the heptagon $M_0 = \mathbf{m}'_0\mathbf{m}'_1 \cdots \mathbf{m}'_6$. From Theorem 1 it then follows that $\phi_i(\mathbf{x}, 0) \geq 0$. For explicit values of \mathbf{f}'_i , see Table 2.

We now consider additional functions $\psi_i(\mathbf{x}, \mathbf{x}')$, $i = 1, \dots, 42$ given by (in each of the definitions that follow $i = 1 \dots, 7$)

$$\begin{aligned} \psi_i &= \langle \mathbf{k}'_{i+4} - \mathbf{m}'_{i+4}, \mathbf{k}'_{i+4} - \mathbf{p}_i(b) \rangle \\ \psi_{i+7} &= \langle \mathbf{k}'_{i+4} - \mathbf{m}'_{i+4}, \mathbf{k}'_{i+4} - \mathbf{p}_i(1-b) \rangle, \\ \psi_{i+14} &= \alpha(\mathbf{p}_i(a), \mathbf{p}_i(b), \mathbf{k}'_{i+4}), \\ \psi_{i+21} &= \alpha(\mathbf{k}'_{i+4}, \mathbf{p}_i(1-b), \mathbf{p}_i(1-a)), \\ \psi_{i+28} &= \alpha(\mathbf{m}'_i, \mathbf{p}_i(a), \mathbf{p}_i(b)), \\ \psi_{i+35} &= \alpha(\mathbf{p}_i(1-b), \mathbf{p}_i(1-a), \mathbf{m}'_{i+1}), \end{aligned}$$

where

$$\alpha(\mathbf{p}, \mathbf{p}', \mathbf{p}'') = \mathbf{p} \wedge \mathbf{p}' + \mathbf{p}' \wedge \mathbf{p}'' + \mathbf{p}'' \wedge \mathbf{p}$$

is the oriented area of the triangle $\mathbf{p}\mathbf{p}'\mathbf{p}''$. From the fact that $\mathbf{m}'_i\mathbf{k}'_i$ is a locally shortest length, we have that a line through \mathbf{k}'_i perpendicular to this length is tangent to M' , and therefore $\psi_i \geq 0$ for $i = 1, \dots, 14$. That $\psi_i \geq 0$ for $i = 15, \dots, 42$ simply follows from convexity. These functions are all analytic in a neighborhood of the origin, and therefore we have that

$$\psi_i(\mathbf{x}, \mathbf{x}') \leq \psi_i(\mathbf{x}, 0) + \langle \mathbf{g}'_i, \mathbf{x}' \rangle + C\|\mathbf{x}'\|(\|\mathbf{x}\| + \|\mathbf{x}'\|).$$

Note that $\psi_i(\mathbf{x}, 0) = 0$ for all $i = 1, \dots, 42$. For explicit values of \mathbf{g}'_i , see Table 2.

There exist coefficients $c_i > 0$, $i = 0, \dots, 6$, and $d_i > 0$, $i = 1, \dots, 42$, such that $\sum_{i=0}^6 c_i \mathbf{f}'_i - \sum_{i=1}^{42} d_i \mathbf{g}'_i = 0$. It then follows from the fundamental theorem of linear algebra that if

$$\begin{aligned} \langle \mathbf{f}'_i, \mathbf{x}' \rangle &\leq 0 \quad \text{for } i = 0, \dots, 6, \\ \langle \mathbf{g}'_i, \mathbf{x}' \rangle &\geq 0 \quad \text{for } i = 1, \dots, 42, \end{aligned}$$

then we have equality for all of the above. The solution space turns out to be trivial. From compactness there must be a constant C such that at least one of the following equations holds for at least one i :

$$\langle \mathbf{f}'_i, \mathbf{x}' \rangle \geq C\|\mathbf{x}'\| \quad \text{or} \quad \langle \mathbf{g}'_i, \mathbf{x}' \rangle \leq -C\|\mathbf{x}'\|.$$

Therefore, it follows from the fact that $\phi_i \leq 0$ and $\psi_i \geq 0$ for all i , that there exists ε such that if $\|\mathbf{x}\|, \|\mathbf{x}'\| < \varepsilon$ then $\mathbf{x}' = 0$. If $\mathbf{x}' = 0$, then from convexity $h_i(t) = 0$ for

all $i = 0, \dots, 6$ and $0 \leq t \leq 1$, and M' is a heptagon. From Theorem 1 M' is affinely equivalent to M . □

Conjecture *The regular heptagon is an absolute minimum of δ_{L^*} in two dimensions.*

If, as might very well be the case, $\delta(M) = \delta_{L^*}(M)$, then the conjecture would also imply that M is a minimum of δ .

$$\begin{aligned} \langle f'_0, e_i \rangle &= \frac{2}{679}(128 - 743u + 816u^2) && \text{for } i = 1 \\ \langle f'_0, e_i \rangle &= 0 && \text{for } i = 2, 4, 6, 8, 10, 12, 14 \\ \langle f'_0, e_i \rangle &= \frac{2}{7}(-4 - 3u + 8u^2) && \text{for } i = 3, 5, 7, 9, 11, 13 \\ \langle f'_0, e_i \rangle &= \frac{2}{7}(-2 - u + 4u^2)v && \text{for } i = 15, 18, 22, 23, 26, 27, \\ &&& 30, 31, 34, 35, 39, 42 \\ \langle f'_0, e_i \rangle &= \frac{2}{7}(-5 - 3u + 10u^2)v && \text{for } i = 16, 17, 20, 21, 25, 28, 29, \\ &&& 32, 36, 37, 40, 41 \\ \langle f'_0, e_i \rangle &= \frac{2}{679}(-618 - 273u + 692u^2)v && \text{for } i = 19, 38 \\ \langle f'_0, e_i \rangle &= \frac{2}{679}(-649 - 1179u + 2010u^2)v && \text{for } i = 24, 33 \\ \langle g'_1, e_1 \rangle &= \langle g'_8, e_1 \rangle = -1 - u \\ \langle g'_1, e_2 \rangle &= -\langle g'_8, e_2 \rangle = \frac{1}{8}(-15 - 2u + 20u^2) \\ \langle g'_1, e_{28} \rangle &= \langle g'_8, e_{29} \rangle = -2(1 + u)v \\ \langle g'_{15}, e_1 \rangle &= \langle g'_{22}, e_1 \rangle = \frac{3}{2}(-3 + 4u^2)v \\ \langle g'_{15}, e_{27} \rangle &= \langle g'_{22}, e_{30} \rangle = \frac{1}{4}(-15 - 2u + 20u^2) \\ \langle g'_{15}, e_{28} \rangle &= \langle g'_{22}, e_{29} \rangle = \frac{1}{2}(-9 - 2u + 14u^2) \\ \langle g'_{29}, e_{27} \rangle &= \langle g'_{36}, e_{30} \rangle = \frac{1}{4}(-7 - 2u + 12u^2) \\ \langle g'_{29}, e_{28} \rangle &= \langle g'_{36}, e_{29} \rangle = \frac{1}{2}(-13 - 2u + 18u^2) \end{aligned}$$

Table 2: Elements of $f'_0, g'_1, g'_8, g'_{15}, g'_{22}, g'_{29}$ and g'_{36} in the standard basis of \mathbb{R}^{14} : elements not given explicitly are zero. The elements of f'_i and g'_i for other values of i are obtained by appropriate permutation of the indices (for example, to obtain $g'_{i+i'}$ from g'_i , cycle the first 14 coordinates by $2i'$ and the last 28 by $4i'$).

3 The 3–ball

Let K and K' be convex bodies and let $\lambda, \lambda' \geq 0$ not both equal to 0, then the set $\lambda K + \lambda' K' = \{\lambda \mathbf{x} + \lambda' \mathbf{x}' \mid \mathbf{x} \in K, \mathbf{x}' \in K'\}$ is also a convex body. This operation is known as the Minkowski sum. A convex body $K \subseteq \mathbb{R}^n$ can be specified by its support height function $h_K: S^{n-1} \rightarrow \mathbb{R}$, given by $h_K(\mathbf{x}) = \max_{\mathbf{y} \in K} \langle \mathbf{x}, \mathbf{y} \rangle$. Minkowski addition corresponds to addition of the support height functions: $h_{\lambda K + \lambda' K'}(\mathbf{x}) = \lambda h_K(\mathbf{x}) + \lambda' h_{K'}(\mathbf{x})$. The mean width of a body K is the average length of its projection onto a randomly chosen axis. It is given by

$$w = \frac{2 \int_{S^{n-1}} h_K d\sigma}{\sigma(S^{n-1})},$$

where σ is the Lebesgue measure on S^{n-1} . Out of all linear images TK of a body K , there is a unique one up to rotation which minimizes w while preserving the volume; see Giannopoulos and Milman [9]. This is known as the minimal mean-width position of K , and a body is in its minimal mean-width position if and only if

$$\int_{S^{n-1}} h_K(\mathbf{x}) \langle \cdot, \mathbf{x} \rangle^2 d\sigma(\mathbf{x}) = (w/2n) \sigma(S^{n-1}) \|\cdot\|^2.$$

Steiner’s formula gives the volume of the body $K_\lambda = (1 - \lambda)B + \lambda K$, interpolating between the unit ball B ($\lambda = 0$) and the body K ($\lambda = 1$). In three dimensions, Steiner’s formula can be written as

$$(3) \quad \text{vol}(K) = \frac{4\pi}{3} (1 - \lambda)^3 + 2\pi w \lambda + S(K) \lambda^2 (1 - \lambda) + \lambda^3 \text{vol}(K),$$

where $S(K)$ is the surface area of K ; see Schneider [21].

In this section we prove the following result about the unit ball and the double-lattice packing density of nearly spherical bodies:

Theorem 3 *Let K be a three-dimensional body in minimal mean-width position. If K is not a ball, then there exist numbers $\lambda_0(K) > 0$ and $\beta(K) > 0$ such that*

$$\delta_{L^*}((1 - \lambda)B + \lambda K) - \delta_{L^*}(B) > \beta(K)\lambda,$$

for all $0 < \lambda < \lambda_0(K)$.

The double-lattice packing density of B is $\pi/\sqrt{18}$. It is realized, for example, by its optimal lattice packing, the face-centered cubic lattice (fcc), which can be described degenerately as a double lattice. It is also realized by the hexagonally closed packed structure (hcp), which is not a Bravais lattice. We fix a realization of the hcp structure in which the unit ball centered at the origin shares the following twelve boundary

points with neighboring balls: $\mathbf{x}_1 = (1, 0, 0)$, $\mathbf{x}_2 = (1/2, \sqrt{3}/2, 0)$, $\mathbf{x}_3 = \mathbf{x}_2 - \mathbf{x}_1$, $\mathbf{x}_4 = -\mathbf{x}_1$, $\mathbf{x}_5 = -\mathbf{x}_2$, $\mathbf{x}_6 = \mathbf{x}_1 - \mathbf{x}_2$, $\mathbf{x}_7 = (1/2, 1/\sqrt{12}, \sqrt{2/3})$, $\mathbf{x}_8 = \mathbf{x}_7 - \mathbf{x}_1$, $\mathbf{x}_9 = \mathbf{x}_7 - \mathbf{x}_2$, $\mathbf{x}_{10} = (1/2, 1/\sqrt{12}, -\sqrt{2/3})$, $\mathbf{x}_{11} = \mathbf{x}_{10} - \mathbf{x}_1$ and $\mathbf{x}_{12} = \mathbf{x}_{10} - \mathbf{x}_2$. The double lattice Ξ , of mean volume $d(\Xi) = 4\sqrt{2}$, is generated by translations by $2\mathbf{x}_1$ and $2\mathbf{x}_2$ and by inversions about \mathbf{x}_7 and \mathbf{x}_{10} . Let P be the polyhedron $\{\mathbf{x} \in \mathbb{R}^3 \mid \langle \mathbf{x}, \mathbf{x}_i \rangle \leq 1 \text{ for all } i = 1, \dots, 12\}$, then P is the Voronoi cell of the hcp structure.

The double lattice Ξ is admissible for P too, producing a packing of density 1, namely a tiling. Specifically, this is a face-to-face tiling in the strong sense that every two cells share a face or do not touch at all. We show now that if K is a nearly spherical convex body, we can bound its double-lattice packing density using the values $h_K(\mathbf{x}_i)$, $i = 1, \dots, 12$.

Lemma 1 *Let K be a convex body satisfying $(1 - \varepsilon)B \subseteq K \subseteq (1 + \varepsilon)B$. For sufficiently small ε , a double-lattice Ξ' exists, admissible for K , such that $d(\Xi') \leq d(\Xi)\eta(K)^3$, where $\eta(K) = \frac{1}{12} \sum_{i=1}^{12} h_K(\mathbf{x}_i)$.*

Proof Without loss of generality, let us assume that $\sum_{i=1}^{12} h_K(\mathbf{x}_i) = 12$. Let us label $h_i = h_K(\mathbf{x}_i)$ and consider be the polyhedron $P' = \{\mathbf{x} \in \mathbb{R}^3 \mid \langle \mathbf{x}, \mathbf{x}_i \rangle \leq h_i \text{ for all } i = 1, \dots, 12\}$. The projection of P' onto the xy -plane is a hexagon. Let \mathbf{a}_1 and \mathbf{a}_2 be the vectors in the xy -plane generating the densest lattice packing of this hexagon. In particular, for ε small enough, there is a unique choice such that $\|\mathbf{a}_1 - 2\mathbf{x}_2\|, \|\mathbf{a}_2 - 2\mathbf{x}_2\| < C\varepsilon$. Now, let $\mathbf{x}'_7, \mathbf{x}'_8$ and \mathbf{x}'_9 be the unique points satisfying $\langle \mathbf{x}'_i, \mathbf{x}_i \rangle = h_i$ for $i = 7, 8, 9$, $\mathbf{x}'_8 = \mathbf{x}'_7 - \frac{1}{2}\mathbf{a}_1$ and $\mathbf{x}'_9 = \mathbf{x}'_7 - \frac{1}{2}\mathbf{a}_2$. Similarly, let $\mathbf{x}'_{10}, \mathbf{x}'_{11}$ and \mathbf{x}'_{12} be the unique points satisfying $\langle \mathbf{x}'_i, \mathbf{x}_i \rangle = h_i$ for $i = 10, 11, 12$, $\mathbf{x}'_{11} = \mathbf{x}'_{10} - \frac{1}{2}\mathbf{a}_1$ and $\mathbf{x}'_{12} = \mathbf{x}'_{10} - \frac{1}{2}\mathbf{a}_2$. Now let Ξ' be the double lattice generated by translations by \mathbf{a}_1 and \mathbf{a}_2 and by inversions about \mathbf{x}'_7 and \mathbf{x}'_{10} . We note that for each face of P' there is a neighbor $\xi'(P')$, $\xi' \in \Xi'$, such that P' and $\xi'(P')$ touch along this face. For small enough ε , this is enough to conclude that Ξ' is admissible for P' , since in the packing $\Xi(P)$ there are only face-to-face contacts. *A fortiori*, Ξ' is also admissible for K .

As $\mathbf{a}_1, \mathbf{a}_2, \mathbf{x}'_7$ and \mathbf{x}'_{10} may be determined explicitly as a function of $h_i, i = 1, \dots, 12$, we calculate the mean volume of Ξ' to be

$$d(\Xi') = 4\sqrt{2} - \frac{\sqrt{2}}{9}(\eta_1 + \eta_2 + \eta_3)^2 - \frac{2\sqrt{2}}{3}(\eta_1^2 + \eta_2^2 + \eta_3^2) + \frac{\sqrt{2}}{9}(\eta_1 + \eta_2 + \eta_3)(2(\eta_1^2 + \eta_2^2 + \eta_3^2) - (\eta_1 + \eta_2 + \eta_3)^2),$$

where $\eta_1 = h_1 + h_4 - 2$, $\eta_2 = h_2 + h_5 - 2$ and $\eta_3 = h_3 + h_6 - 2$. Note that the quadratic term is negative unless $\eta_1 = \eta_2 = \eta_3 = 0$, in which case the quadratic and cubic term both vanish. Therefore, when ε is small enough $d(\Xi') \leq 4\sqrt{2}$. \square

Lemma 2 *Let*

$$c_l = P_l(1) + 4P_l(\frac{1}{2}) + 2P_l(0) + P_l(-\frac{1}{3}) + 2P_l(-\frac{1}{2}) + 2P_l(-\frac{5}{6}),$$

where $P_l(t)$ is the Legendre polynomial of degree l . Then $c_l = 0$ if and only if $l = 1$ or $l = 2$.

Proof We introduce the following rescaled Legendre polynomials: $Q_l(t) = 6^l l! P_l(t)$. From their recurrence relation $Q_{l+1}(t) = (2l + 1)(6t)Q_l(t) - 36l^2 Q_{l-1}(t)$ and the base cases, $Q_0(t) = 1$ and $Q_1(t) = 6t$, it is clear that the values of $Q_l(t)$ at $t = k/6$ for $k = -6, \dots, 6$ are integers. If $Q_l(k/6) \equiv Q_{l+1}(k/6) \equiv 0 \pmod{8}$ for some k and l then for all $l' \geq l$, $Q_{l'}(k/6) \equiv 0 \pmod{8}$. This is the case for $k = 0, 2, 6$ and $l = 3$, as can be easily checked.

For $k = 3$ and $k = 5$ it is easy to show by induction that the residue of $Q_l(k/6)$ modulo 8 depends only on k and the residue of l modulo 4 and takes the values

$$\begin{aligned} Q_l(\frac{1}{2}) &\equiv 1, 3, 7, 1 \pmod{8}, \\ Q_l(\frac{5}{6}) &\equiv 1, 5, 7, 7 \pmod{8}, \end{aligned}$$

resp. for $l \equiv 0, 1, 2, 3 \pmod{4}$. Therefore, when $l \geq 3$ is odd, then $6^l l! c_l = Q_l(1) - 2Q_l(\frac{5}{6}) + 2Q_l(\frac{1}{2}) - Q_l(\frac{1}{3}) \equiv 4 \pmod{8}$, and therefore cannot vanish. When $l \geq 3$ is even, then $6^l l! c_l = Q_l(1) + 2Q_l(\frac{5}{6}) + 6Q_l(\frac{1}{2}) + Q_l(\frac{1}{3}) + 2Q_l(0) \equiv 8 \pmod{16}$, and again cannot vanish. This leaves only the cases $c_0 = 12$, $c_1 = 0$, and $c_2 = 0$ to be calculated manually. \square

Lemma 3 *Let K be a three-dimensional body in minimal mean-width position. If K is not a ball then there is a body K' , isometric to K , such that $\eta(K') < \frac{1}{2}w$, where w is the mean width of K .*

Proof Note that if $K' = R(K)$ is a rotation of K about the origin, then $h_{K'}(\mathbf{x}) = h_K(R^T \mathbf{x})$. Let us pick a point $\mathbf{y} \in S^2$, and let R_0 be some rotation such that $R_0(\mathbf{y}) = \mathbf{x}_7$. Let R_θ be the rotation obtained by composing R_0 with a rotation by θ about the axis through \mathbf{x}_7 , so that $R_\theta(\mathbf{y}) = \mathbf{x}_7$ for all $0 \leq \theta \leq 2\pi$. Now let

$$g(\mathbf{y}) = \frac{1}{2\pi} \int_0^{2\pi} \eta(R_\theta(K)) d\theta,$$

and repeat this definition for all $\mathbf{y} \in S^2$.

The function $g(\mathbf{y})$ is given by integrating $h_K(\mathbf{x})$ over a measure $\mu_{\mathbf{y}}(\mathbf{x})$. The measures $\mu_{\mathbf{y}}(\mathbf{x})$ are each invariant under rotations about the axis through \mathbf{y} , and are related to each other by rotations. Such an operation $h_K(\mathbf{x}) \mapsto g(\mathbf{y})$ is known as a convolution by the zonal measure $\mu_{\mathbf{p}}(\mathbf{x})$, where \mathbf{p} is some arbitrary pole (see Schuster [22] for results about convolutions with zonal measures). The measure $\mu_{\mathbf{p}}$ is given by

$$12\mu_{\mathbf{p}}(\{\mathbf{x} \mid \langle \mathbf{p}, \mathbf{x} \rangle \in (t_1, t_2)\}) = |\{i \in \{1, 2, \dots, 12\} \mid \langle \mathbf{x}_7, \mathbf{x}_i \rangle \in (t_1, t_2)\}|.$$

We can expand $\mu_{\mathbf{p}}(\mathbf{x})$ into spherical harmonics to obtain

$$\mu_{\mathbf{p}}(\mathbf{x}) = \frac{1}{12} \sum_{l=0}^{\infty} c_l P_l(\langle \mathbf{x}, \mathbf{p} \rangle),$$

where c_l are the coefficients of Lemma 2. It follows that if $h_K(\mathbf{x}) = \sum_{l=0}^{\infty} h_l(\mathbf{x})$ is the expansion of h_K into spherical harmonics, then $g(\mathbf{x}) = \frac{1}{12} \sum_{l=0}^{\infty} c_l h_l(\mathbf{x})$ [22]. The $l = 0$ term of $g(\mathbf{x})$, giving its average value, is equal to that of $h_K(\mathbf{x})$, namely $w/2$. Because K is in minimal mean-width position, $h_2 = 0$. Therefore, by Lemma 2, $g(\mathbf{x})$ is constant if and only if the spherical harmonics expansion of h_K terminates at $l = 1$, which in turn is equivalent to K being a ball. Since we assume K is not a ball, then $g(\mathbf{x})$ is not constant and must achieve a value below its average. Since this value corresponds in turn to an average of values of $\eta(R(K))$ over a set of rotations R , it must be no smaller than the minimum value among these rotations. Therefore, there is a rotation R such that $\eta(R(K)) < w/2$. □

We now prove Theorem 3.

Proof Without loss of generality, we may assume that $\text{vol}(K) = \text{vol}(B)$ and that K is rotated such that $\eta(K) < w/2$. Let $K_{\lambda} = (1-\lambda)B + \lambda K$, then $\eta(K_{\lambda}) = 1 + (\eta(K) - 1)\lambda$. The isoperimetric inequality, $S(K) > S(B)$, and Steiner’s formula (3) give

$$\frac{\text{vol}(K_{\lambda})}{\text{vol}(B)} \geq 1 + 3(\frac{1}{2}w - 1)\lambda(1 - \lambda)^2.$$

The claim of the theorem now follows immediately from Lemma 1. □

Conjecture *The ball is a local minimum of δ_{L^*} in two dimensions.*

It does not seem that the ball is a global minimum of δ_{L^*} . For example, the densest-known double-lattice packing of the tetrahedron T has a density of only $\frac{1}{369}(139 + 40\sqrt{10}) = 0.71948\dots$, so probably $\delta_{L^*}(T) < \delta_{L^*}(B)$; see the author, Elser and Gravel [14]. Still, if the conjecture holds, then the ball would also be a local minimum of δ , verifying a local version of Ulam’s conjecture.

4 Discussion

We conclude with a summary of known results and open problems. Recall from the introduction that Problems 1–3 ask for bodies that minimize the functions δ , δ_L , δ_{L^*} , δ_T , or δ_{T^*} either among all convex bodies or among only cs bodies. There are only two cases that are solved: the minimum of δ_L and δ_T in two dimensions among all convex bodies is $\frac{2}{3}$, as realized by triangles alone [6; 3]. A Bezdek and W Kuperberg comment that determining the minima in the unsolved cases “seems to be a very challenging problem, perhaps too difficult to expect to be solved in foreseeable future” [1]. Determining local minima seems to be a more approachable problem, and so far the following local minima have been identified:

- Reinhardt’s smoothed octagon is a local minimum of δ_L and of δ_T among cs bodies in two dimensions [18].
- The ball is a local minimum of δ_L and of δ_T among cs bodies in three dimensions; see the author [13].
- The regular heptagon is a local minimum of δ_{L^*} among all convex bodies in two dimensions (Section 2).

Note that the present work is the only case in the list above of a local minimum among all convex bodies. Reinhardt’s smoothed octagon possesses the property that its lattice packing density is achieved simultaneously by a one-parameter family of lattices (see Figure 1). In fact this property, common to all so-called irreducible domains (domains all of whose proper subdomains have admissible lattices of lower mean area), has long been a central organizing idea in the study of Reinhardt’s conjecture [17]. Therefore, it might be surprising to some that the heptagon, despite being irreducible with respect to double lattices, does not have a one parameter family of optimal admissible double lattices.

We end with three open problems:

- The conjecture that the ball is a global minimum of δ among convex bodies in three dimensions has been attributed to Ulam [8]. A weaker claim, that the ball is a local minimum of δ , is open. It is also possible that the ball is a local minimum of δ_{T^*} or of δ_{L^*} , as we conjecture here (Section 3). Either of these possibilities necessarily imply that the ball is a local minimum of δ , but they do not necessarily follow from Ulam’s conjecture.
- The regular heptagon is conjectured to be a local minimum of δ among convex bodies in two dimensions. This would follow immediately if the packing density of the regular heptagon is shown to be equal to its double-lattice packing density.

- In four dimensions, we know by earlier work that the ball is not a minimum of δ_L among cs bodies [13]. It would be interesting to identify a body which is such a minimum.

Acknowledgements I would like to thank Wlodzimierz Kuperberg for his helpful comments.
