On d -dimensional dual hyperovals in $\text{PG}(2d, 2)$

Hiroaki Taniguchi

Abstract

We show that d -dimensional dual hyperovals in $\text{PG}(2d, 2)$ constructed from a regular nearfield of characteristic 2 are not isomorphic to Yoshiara's d -dimensional dual hyperovals in $\text{PG}(2d, 2)$ constructed in [5]. Thus we show that, in Cooperstein-That's family [1], there exist non-isomorphic dual hyperovals.

Keywords: dual hyperoval

MSC 2000: 05-xx

1. Introduction

Let $\text{GF}(q)$ be a finite field with q elements. Let d, m be integers with $d \geq 2$ and $m > d$. Let $\text{PG}(m, 2)$ be an m -dimensional projective space over the binary field $\text{GF}(2)$.

Definition 1.1. A family S of d -dimensional subspaces of $\text{PG}(m, 2)$ is called a d -dimensional dual hyperoval in $\text{PG}(m, 2)$ if it satisfies the following conditions:

- (1) any two distinct members of S intersect in a projective point,
- (2) no three mutually distinct members of S have a common projective point,
- (3) all members of S generate $\text{PG}(m, 2)$, and
- (4) there are exactly 2^{d+1} members of S .

In Example 2.5 and Theorem 6.1 of [1] (see also Proposition 3.1 of [2]), B. N. Cooperstein and J. A. That's showed that each d -dimensional dual hyperoval in $\text{PG}(2d, 2)$ is obtained as a dual of a partition of $\text{PG}(2d, 2) \setminus \text{PG}(d, 2)$.

Theorem 1.2 ([1, Example 2.5 and Theorem 6.1]). *Let $PG(d, 2)$ be a d -dimensional subspace of $PG(2d, 2)$. Consider a partition of $PG(2d, 2) \setminus PG(d, 2)$ into 2^{d+1} $(d - 1)$ -dimensional subspaces. Then the set S of the dual subspaces of these $(d - 1)$ -dimensional subspaces in $PG(2d, 2)$ is a d -dimensional dual hyperoval in $PG(2d, 2)$. The converse also holds.*

This family is called as Cooperstein-Thas's family in [2]. In [5] (see also [6]), Yoshiara constructed a family of d -dimensional dual hyperovals in $PG(2d, 2)$ in a different way, as follows.

Theorem 1.3 ([5, Proposition 3]). *Let σ be a generator of the automorphism group of $GF(2^{d+1})$ over $GF(2)$. Inside $GF(2^{d+1}) \oplus GF(2^{d+1})$, let us define $X_Y(t)$ for $t \in GF(2^{d+1})$ as*

$$X_Y(t) := \left\{ (x, x^\sigma t + xt^{\sigma^{-1}}) \mid x \in GF(2^{d+1}) \setminus \{0\} \right\}.$$

Then $S_Y := \{X_Y(t) \mid t \in GF(2^{d+1})\}$ is a d -dimensional dual hyperoval in $PG(2d, 2)$.

Then, it is quite natural to ask whether all the members of the Cooperstein-Thas's family are the Yoshiara's dual hyperovals or not. In the case $d = 2$, the answer is affirmative ([2, Theorem 1]). In this paper, we will give a negative answer to this question in general.

Definition 1.4 ([3]). Let Π be a vector space over $GF(q)$. A spread T of Π is a collection of at least two subspaces of Π which satisfies the following conditions:

- (1) two distinct elements of T are isomorphic subspaces,
- (2) every point except $\{0\}$ of Π is on exactly one subspace in T , and
- (3) for any $U_1, U_2 \in T$ with $U_1 \neq U_2$, Π is a direct (vector space) sum of U_1 and U_2 .

It is known that the vector space Π has even dimension $2m$ with $m > 0$. Moreover, the cardinality of the spread $|T| = q^m + 1$. (See [3] or [4].)

From spreads of the vector space $V \oplus V$, where V is a $(d + 1)$ -dimensional vector space over $GF(2)$, we are able to construct d -dimensional dual hyperovals as follows:

Theorem 1.5. *Let $V := GF(2)^{d+1}$ be a $(d + 1)$ -dimensional vector space over $GF(2)$, and $T := \{K_0, K_1, \dots, K_{2^{d+1}-1}\}$ a spread of $V \oplus V$. Let v be a non-zero element of $V \oplus V$. We may assume that v is contained in K_0 . Let*

$$\pi: V \oplus V \ni x \mapsto \bar{x} \in \overline{V \oplus V} := (V \oplus V) / \langle v \rangle$$

ACADEMIA
PRESS

be a $\text{GF}(2)$ -linear mapping with kernel $\{0, v\}$ (which we denote by $\langle v \rangle$), and image $(V \oplus V)/\langle v \rangle$. We regard $\text{PG}((V \oplus V)/\langle v \rangle) = \text{PG}(2d, 2)$. Then,

$$S := \{\pi(K_1) \setminus \{0\}, \pi(K_2) \setminus \{0\}, \dots, \pi(K_{2^{d+1}}) \setminus \{0\}\}$$

is a d -dimensional dual hyperoval in $\text{PG}(2d, 2)$.

We will give the proof of this theorem in the following section. We refer the relations among spreads, quasifields and translation affine planes to Kallaher [3] or Lüneburg [4].

Example 1. We regard $V := \text{GF}(2^{d+1})$ as a $(d + 1)$ -dimensional vector space over $\text{GF}(2)$. Let σ be a generator of the Galois group $\text{Gal}(\text{GF}(2^{d+1})/\text{GF}(2))$. Let

$$\pi' : \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1}) \ni (x, y) \mapsto (x, y^\sigma + y) \in \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1}).$$

Then it is easy to see that the kernel of π' is $\{(0, 0), (0, 1)\}$, and the image of π' is $W := \{(x, y) \mid \text{Tr}(y) = 0\}$, which is a $(2d + 1)$ -dimensional vector space over $\text{GF}(2)$, where Tr is a trace function from $\text{GF}(2^{d+1})$ to $\text{GF}(2)$.

In $V \oplus V$, let

$$K_\infty := \{(0, x) \mid x \in \text{GF}(2^{d+1})\} \text{ and}$$

$$K_a := \{(x, xa) \mid x \in \text{GF}(2^{d+1})\} \text{ for } a \in \text{GF}(2^{d+1}).$$

Then, $T := \{K_\infty\} \cup \{K_a \mid a \in \text{GF}(2^{d+1})\}$ is a spread of $V \oplus V$. (It is well known that the translation affine plane constructed from this spread is a Desarguesian affine plane.) Let $S' := \{\pi'(K_a) \setminus \{0\} \mid a \in \text{GF}(2^{d+1})\}$. Then, by Theorem 1.5, S' is a d -dimensional dual hyperoval in $\text{PG}(2d, 2) = \text{PG}(W)$.

Proposition 1.6. The dual hyperoval S' above is isomorphic to Yoshiara's dual hyperoval S_Y .

Proof. We have $\pi'(K_a) \setminus \{0\} = \{(x, (ax)^\sigma + ax) \mid x \in \text{GF}(2^{d+1}) \setminus \{0\}\}$. If we put $a^\sigma := t$, then $a = t^{\sigma^{-1}}$, hence we have

$$\begin{aligned} \{(x, (ax)^\sigma + ax) \mid x \in \text{GF}(2^{d+1}) \setminus \{0\}\} \\ = \{(x, x^\sigma t + xt^{\sigma^{-1}}) \mid x \in \text{GF}(2^{d+1}) \setminus \{0\}\}. \end{aligned}$$

Therefore, we have $\pi'(K_a) \setminus \{0\} = X_Y(t)$, where $X_Y(t)$ is as in Theorem 1.3. Hence, we have $\{\pi'(K_a) \setminus \{0\} \mid a \in \text{GF}(2^{d+1})\} = \{X_Y(t) \mid t \in \text{GF}(2^{d+1})\}$ and consequently, we have $S' = S_Y$. \square

Now, we will use quasifields Q to construct spreads of $Q \oplus Q$.

page 4 / 9

go back

quit

Definition 1.7 ([3, 4]). An algebraic structure $(Q; +, \circ)$ is called a quasifield if it satisfies the following conditions:

- (i) Q is an abelian group under $+$ with identity 0 ;
- (ii) for $a, c \in Q$ with $a \neq 0$, there exists exactly one $x \in Q$ such that $a \circ x = c$;
- (iii) for $a, b, c \in Q$ with $a \neq b$, there exists exactly one $x \in Q$ such that $x \circ a - x \circ b = c$;
- (iv) for all $a \in Q$, $a \circ 0 = 0 \circ a = 0$;
- (v) there exists an element $1 \in Q \setminus \{0\}$ such that $1 \circ a = a \circ 1 = a$ for all $a \in Q$;
- (vi) for all $a, b, c \in Q$, $(a + b) \circ c = a \circ c + b \circ c$.

A nearfield is a quasifield N in which the multiplication \circ is associative; that is, in which $(N \setminus \{0\}, \circ)$ is a group. A semifield is a quasifield S in which the left distributive law

$$a \circ (b + c) = a \circ b + a \circ c$$

holds for all $a, b, c \in S$.

In $Q \oplus Q$, we define $K_\infty := \{(0, y) \mid y \in Q\}$ and $K_a := \{(x, x \circ a) \mid x \in Q\}$ for $a \in Q$. Then it is known that $\{K_\infty\} \cup \{K_a \mid a \in Q\}$ is a spread of $Q \oplus Q$.

Example 2 ([3, 2.1 and 2.3]). Consider the field $\text{GF}(q^n)$ where $n \geq 1$ and $q = p^s$ with p a prime and $s \geq 1$. Let $\lambda : \text{GF}(q^n) \rightarrow I_n = \{0, 1, \dots, n-1\}$ be a mapping satisfying: (i) $\lambda(0) = \lambda(1) = 0$, and (ii) given $a, b \in \text{GF}(q^n) \setminus \{0\}$ there exists $x \neq 0$ with

$$x^{q^{\lambda(a)}} a = x^{q^{\lambda(b)}} b$$

if and only if $a = b$. We define $x \circ y := x^{q^{\lambda(y)}} y$. Then $(\text{GF}(q^n), +, \circ)$ is a quasifield called a generalized André system.

Consider also the field $\text{GF}(q^n)$ and $q = p^s$ with p a prime and $s \geq 1$, and assume every prime divisor of n divides $q - 1$. Also assume $n \not\equiv 0 \pmod{4}$ if $q \equiv 3 \pmod{4}$. Choosing a primitive element ω of $\text{GF}(q^n)$, define $\lambda : \text{GF}(q^n) \setminus \{0\} \rightarrow I_n = \{0, 1, \dots, n-1\}$ by

$$(q^{\lambda(a)} - 1)(q - 1)^{-1} \equiv i \pmod{n}, \text{ where } a = \omega^i \in \text{GF}(q^n).$$

With $\lambda(0) = 0$, the mapping λ satisfies the conditions (i) and (ii) for a generalized André system. This system, denoted by $N(q, n)$, is a nearfield and is called a regular nearfield (or a Dickson nearfield).

Proposition 1.8 ([4, Theorem 7.3 and Theorem 7.4]). The group consisting of non-zero elements of the regular nearfield $(N(q, n) \setminus \{0\}, \circ)$ in Example 2 is a non-abelian metacyclic group. Moreover, there exist $\phi(n)/m$ non-isomorphic $N(q, n)$'s, where ϕ is the Euler function and m is the order of $p \pmod{n}$.

Moreover, it is known that, in $\text{GF}(2^{d+1})$, using a natural addition of the field $\text{GF}(2^{d+1})$, we are able to define more multiplications \circ so that we have some semifields, such as Knuth semifields, Kantor semifields or Albert semifields, and so on. (See [3].)

Definition 1.9 (Dual hyperoval S_K). Let $(\text{GF}(2^{d+1}), +, \circ)$ be a quasifield, and regard $V := \text{GF}(2^{d+1})$ as a vector space over $\text{GF}(2)$. In $V \oplus V$, we define

$$K_\infty := \{(0, x) \mid x \in \text{GF}(2^{d+1})\} \text{ and}$$

$$K_a := \{(x, x \circ a) \mid x \in \text{GF}(2^{d+1})\} \text{ for } a \in \text{GF}(2^{d+1}).$$

Then, $T := \{K_\infty\} \cup \{K_a \mid a \in \text{GF}(2^{d+1})\}$ is a spread of $V \oplus V$. Let σ be a generator of the Galois group $\text{Gal}(\text{GF}(2^{d+1})/\text{GF}(2))$. Let π' be a $\text{GF}(2)$ -linear mapping defined by

$$\pi' : \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1}) \ni (x, y) \mapsto (x, y^\sigma + y) \in \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1}).$$

Then, as in Example 1, the image of π' is $W := \{(x, y) \mid \text{Tr}(y) = 0\}$, which is a $(2d + 1)$ -dimensional vector space over $\text{GF}(2)$. We note that the kernel of π' , $\{(0, 0), (0, 1)\}$, is contained in K_∞ . We define $X_K(a) := \pi'(K_a) \setminus \{0\}$. Then, by Theorem 1.5, $S_K := \{X_K(a) \mid a \in \text{GF}(2^{d+1})\}$ is a d -dimensional dual hyperoval in $\text{PG}(2d, 2) = \text{PG}(W)$, where

$$X_K(a) = \{(x, (x \circ a)^\sigma + x \circ a) \mid x \in \text{GF}(2^{d+1}) \setminus \{0\}\}.$$

Then we have the following proposition.

Proposition 1.10. *If the algebraic system $(\text{GF}(2^{d+1}), +, \circ)$ is a regular nearfield, then the automorphism group G_K of the dual hyperoval S_K contains the subgroup $N := \{n_b \mid b \in \text{GF}(2^{d+1}) \setminus \{0\}\}$ with $n_b(X_K(t)) = X_K(b \circ t)$ defined by*

$$n_b((x, y)) := (x \circ b', y),$$

where b' is an element which satisfies that $b' \circ b = 1$. Moreover, N is isomorphic to the group $(\text{GF}(2^{d+1}) \setminus \{0\}, \circ)$, and so, by Proposition 1.8, N is a non-abelian metacyclic group with the cardinality $|N| = 2^{d+1} - 1$. If the algebraic system $(\text{GF}(2^{d+1}), +, \circ)$ is a semifield, then the automorphism group G_K of the dual hyperoval S_K contains the subgroup $T := \{t_a \mid a \in \text{GF}(2^{d+1})\}$ with $t_a(X_K(t)) = X_K(t + a)$, defined by

$$t_a((x, y)) := (x, y + (x \circ a)^\sigma + x \circ a),$$

and T is isomorphic to $\text{GF}(2^{d+1})$ as an additive group.

ACADEMIA
PRESS

Proof. Since the multiplication \circ is associative in the regular nearfield, we have

$$n_b(X_K(t)) = \{(x \circ b', ((x \circ b') \circ (b \circ t))^\sigma + (x \circ b') \circ (b \circ t))\} = X_K(b \circ t)$$

for $b \in \text{GF}(2^{d+1}) \setminus \{0\}$. Hence

$$n_{b_2}(n_{b_1}(X_K(t))) = n_{b_2}(X_K(b_1 \circ t)) = X_K((b_2 \circ b_1) \circ t) = n_{b_2 \circ b_1}(X_K(t))$$

for $b_1, b_2 \in \text{GF}(2^{d+1}) \setminus \{0\}$. Therefore $N := \{n_b \mid b \in \text{GF}(2^{d+1}) \setminus \{0\}\}$ is isomorphic to the group $(\text{GF}(2^{d+1}) \setminus \{0\}, \circ)$. Since the multiplication \circ has left distributive law in the semifield, we also have

$$t_a(X_K(t)) = \{(x, (x \circ t)^\sigma + x \circ t + (x \circ a)^\sigma + x \circ a)\} = X_K(t + a),$$

hence we have $T \cong \text{GF}(2^{d+1})$ as an additive group. \square

By Theorem 1.2 (see also [2, 1.2. Examples (a)]), the complement of the points on the members of the dual hyperoval in $\text{PG}(2d, 2)$, that is,

$$\text{PG}(2d, 2) \setminus \bigcup \{\text{the points on the members of the dual hyperoval}\}$$

is a $(d - 1)$ -dimensional subspace. Hence we have the following lemma.

Lemma 1.11. *Let $U := \{(0, y) \mid y \in \text{GF}(2^{d+1}), \text{Tr}(y) = 0\}$. Note that $U \subset W := \{(x, y) \mid x, y \in \text{GF}(2^{d+1}), \text{Tr}(y) = 0\}$. Then, in $\text{PG}(2d, 2) = \text{PG}(W)$, the $(d - 1)$ -dimensional subspace $\text{PG}(U)$ is the complement of the set $\bigcup X_K(a)$ of the points which are on some members of the dual hyperoval S_K in Definition 1.9, that is,*

$$\text{PG}(U) = \text{PG}(W) \setminus \bigcup_{a \in \text{GF}(2^{d+1})} X_K(a).$$

In section 3, we will prove the following theorem, hence we give a negative answer to the previous question.

Theorem 1.12. *Let the algebraic system $(\text{GF}(2^{d+1}), +, \circ)$ in Example 2 be a regular nearfield. Then, a d -dimensional dual hyperoval S_K in $\text{PG}(2d, 2)$ in Definition 1.9 is not isomorphic to the Yoshiara's dual hyperoval S_Y .*

2. Proof of Theorem 1.5

Since $K_i \not\ni v$ for $1 \leq i \leq 2^{d+1}$, $\pi(K_i) \setminus \{0\}$ is a d -dimensional subspace in $\text{PG}(2d, 2) = \text{PG}((V \oplus V)/\langle v \rangle)$ for $1 \leq i \leq 2^{d+1}$. Let $\pi(K_i) \setminus \{0\}$ and $\pi(K_j) \setminus \{0\}$ have a common point $\pi(x_i) = \pi(x_j)$ for $x_i \in K_i \setminus \{0\}$ and $x_j \in K_j \setminus \{0\}$ with $1 \leq i < j \leq 2^{d+1}$. Then, since $\pi(x_i + x_j) = 0$, we have $x_i + x_j = v$. However,

ACADEMIA
PRESS

quit

since $V \oplus V$ is a direct sum of K_i and K_j by (3) of Definition 1.4, there exist unique $x_i \in K_i \setminus \{0\}$ and unique $x_j \in K_j \setminus \{0\}$ which satisfies that $x_i + x_j = v$. Thus, we have proved that $\pi(K_i) \setminus \{0\}$ and $\pi(K_j) \setminus \{0\}$ have only one common point. Assume that $\pi(K_s) \setminus \{0\}$, $\pi(K_t) \setminus \{0\}$ and $\pi(K_u) \setminus \{0\}$ have a common point $\pi(x_s) = \pi(x_t) = \pi(x_u)$ for $x_s \in K_s \setminus \{0\}$, $x_t \in K_t \setminus \{0\}$ and $x_u \in K_u \setminus \{0\}$ with $1 \leq s < t < u \leq 2^{d+1}$. Then, since $\pi(x_s + x_t) = 0$, we have $x_s + x_t = v$. We also have $x_s + x_u = v$. However, we have $x_t = x_u$ from these equations, which contradicts (2) of Definition 1.4. Hence $\pi(K_s) \setminus \{0\}$, $\pi(K_t) \setminus \{0\}$ and $\pi(K_u) \setminus \{0\}$ with $1 \leq s < t < u \leq 2^{d+1}$ have no common point. Since the cardinality

$$|S| = |\{\pi(K_1) \setminus \{0\}, \pi(K_2) \setminus \{0\}, \dots, \pi(K_{2^{d+1}}) \setminus \{0\}\}| = 2^{d+1},$$

and since it is trivial that all members of S generate $\text{PG}(2d, 2)$, we conclude that S is a d -dimensional dual hyperoval in $\text{PG}(2d, 2) = \text{PG}((V \oplus V)/\langle v \rangle)$. \square

3. Proof of Theorem 1.12

We consider the dual hyperovals inside the projective space

$$\text{PG}(2d, 2) = \{(x, y) \mid (x, y) \in \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1}) \setminus \{(0, 0)\}, \text{Tr}(y) = 0\}.$$

We recall that an automorphism of the dual hyperoval S in $\text{PG}(2d, 2)$ is a linear transformation which permute the members of S . We also define an isomorphism of the dual hyperovals S to S' as a linear transformation of $\text{PG}(2d, 2)$ which sends each member of S to that of S' .

Let $d+1 = sn$ with $s \geq 1$, and assume every prime divisor of n divides $2^s - 1$. (For example, $(s, n) = (4, 3)$, etc.) Then, by Example 2, we are able to define a multiplication \circ of $\text{GF}(2^{d+1})$ such that $(\text{GF}(2^{d+1}), +, \circ)$ is a regular near field. Hence, by Definition 1.9, we have a dual hyperoval

$$S_K = \{X_K(t) \mid t \in \text{GF}(2^{d+1})\},$$

where

$$X_K(t) := \{(x, (x \circ t)^\sigma + x \circ t) \mid x \in \text{GF}(2^{d+1}) \setminus \{0\}\}.$$

By Proposition 1.10, the automorphism group G_K of the dual hyperoval S_K contains a subgroup $N := \{n_b \mid b \in \text{GF}(2^{d+1}) \setminus \{0\}\}$ with $n_b(X_K(t)) = X_K(b \circ t)$ defined by

$$n_b((x, y)) := (x \circ b', y),$$

where $b' \circ b = 1$. Let $G_K(0)$ be a subgroup of G_K which fixes $X_K(0) := \{(x, 0) \mid x \in \text{GF}(2^{d+1})\}$. Then it is easy to see that $N \subset G_K(0)$. By Proposition 1.8, N is a non-abelian metacyclic group with the cardinality $|N| = 2^{d+1} - 1$.

We recall that the automorphism group G_Y of Yoshiara's dual hyperoval S_Y is generated by the groups T , M and F , where $T = \{t_a \mid a \in \text{GF}(2^{d+1})\}$ with $t_a(X_Y(t)) = X_Y(t + a)$ defined by

$$t_a: (x, y) \mapsto (x, x^\sigma a + xa^{\sigma^{-1}} + y),$$

$M = \{m_b \mid b \in \text{GF}(2^{d+1}) \setminus \{0\}\}$ with $m_b(X_Y(t)) = X_Y(bt)$ defined by

$$m_b: (x, y) \mapsto (xb^{-1}, y),$$

and $F = \{f_\tau \mid \tau \in \text{Gal}(\text{GF}(2^{d+1})/\text{GF}(2))\}$ with $f_\tau(X_Y(t)) = X_Y(t^\tau)$ defined by

$$f_\tau: (x, y) \mapsto (x^\tau, y^\tau).$$

We also have $G_Y = T : (M : F)$. Hence G_Y is doubly transitive on the members of S_Y . (See [5, Proposition 7].) We note that M is a cyclic group with cardinality $|M| = 2^{d+1} - 1$.

Let $G_Y(0)$ be a subgroup of G_Y which fixes $X_Y(0) := \{(x, 0) \mid x \in \text{GF}(2^{d+1})\}$. Then, we have $G_Y(0) = M : F$ from the expressions of T , M and F and the fact that $G_Y = T : (M : F)$.

Lemma 3.1. *Let g be an element of $G_Y(0) = M : F$ with the action $g: (x, y) \mapsto (g_1(x, y), g_2(x, y))$, where g_1 and g_2 are $\text{GF}(2)$ -linear mapping. If $g_2(x, y) = y$ for any $(x, y) \in \text{GF}(2^{d+1}) \oplus \text{GF}(2^{d+1})$ with $\text{Tr}(y) = 0$, then we have $g \in M$.*

Proof. Let $g = m_b f_\tau \in G_Y(0) = M : F$, then $g(x, y) = (x^\tau (b^{-1})^\tau, y^\tau)$ by definition. Assume that $g_2(x, y) = y^\tau = y$ for any $y \in \text{GF}(2^{d+1})$ with $\text{Tr}(y) = 0$. Then, since the subset $\{y \in \text{GF}(2^{d+1}) \mid \text{Tr}(y) = 0\}$ is not contained in any proper subfield of $\text{GF}(2^{d+1})$, we have $\tau = \text{id} \in \text{Gal}(\text{GF}(2^{d+1})/\text{GF}(2))$. Hence we have $g \in M$. \square

We assume to the contrary that there exists an isomorphism i from S_K to S_Y . Since G_Y is doubly transitive on the members of S_Y , we may assume that $i(X_K(0)) = X_Y(0)$, that is, i maps $\{(x, 0) \mid x \in \text{GF}(2^{d+1})\}$ onto itself. Hence, we may assume that i maps $G_K(0)$ to $G_Y(0)$. On the other hand, since i is an isomorphism from $S_K = \{X_K(t) \mid t \in \text{GF}(2^{d+1})\}$ to $S_Y = \{X_Y(t) \mid t \in \text{GF}(2^{d+1})\}$, we have

$$i\left(\bigcup_{t \in \text{GF}(2^{d+1})} X_K(t)\right) = \bigcup_{t \in \text{GF}(2^{d+1})} X_Y(t).$$

Hence, by Lemma 1.11, we have

$$\begin{aligned} i(U) &= i\left(\text{PG}(2d, 2) \setminus \bigcup_{t \in \text{GF}(2^{d+1})} X_K(t)\right) \\ &= \text{PG}(2d, 2) \setminus \bigcup_{t \in \text{GF}(2^{d+1})} X_Y(t) = U, \end{aligned}$$

ACADEMIA
PRESS

which means that i maps $\{(0, y) \mid y \in \text{GF}(2^{d+1}), \text{Tr}(y) = 0\}$ onto itself. Therefore, there exist $\text{GF}(2)$ -linear mapping f and g such that the isomorphism i is expressed as follows:

$$i((x, y)) = (f(x), g(y)). \quad (1)$$

Now, we have $i(N) = \{i(n_b) \mid b \in \text{GF}(2^{d+1}) \setminus \{0\}\} \cong N$ as a subgroup of $G_Y(0) = M : F$ with the action $i(n_b)(X_Y(t)) = i(n_b(i^{-1}(X_Y(t))))$ for $X_Y(t) \in S_Y$. Then, by (1), the action of $i(n_b)$ is

$$i(n_b): (x, y) \mapsto (f(f^{-1}(x) \circ b'), y).$$

Hence, by Lemma 3.1, $i(N)$ is a subgroup of $M \subset G_Y(0)$. However, the cardinality $|i(N)| = |M| = 2^{d+1} - 1$. Moreover, N is a non-abelian metacyclic group and M is a cyclic group. This is impossible. Hence, we have a contradiction. Therefore, we finally have that the dual hyperoval S_K is not isomorphic to the Yoshiara's dual hyperoval S_Y . \square
