# Log-concavity of Hölder means and an application to geometric inequalities

Aurel I. Stan and Sergio D. Zapeta-Tzul

(Communicated by Sever S. Dragomir)

The log-concavity of the Hölder mean of two numbers, as a function of its index, is presented first. The notion of  $\alpha$ -cevia of a triangle is introduced next, for any real number  $\alpha$ . We use this property of the Hölder mean to find the smallest index  $p(\alpha)$  such that the length of an  $\alpha$ -cevia of a triangle is less than or equal to the  $p(\alpha)$ -Hölder mean of the lengths of the two sides of the triangle that are adjacent to that cevia.

## 1. Introduction

All parts of mathematics are interconnected, including two important branches, geometry and analysis. Continuity, which is a fundamental notion in real analysis, is used in Euclidean geometry as one axiom in Hilbert axiomatization, and in proving Thales' theorem for irrational ratios. On the other hand, geometry helps real analysis by providing pictures that help us understand certain theorems. For example, Euler's theorem, which says that in any parallelogram the sum of the squares of the lengths of its sides is equal to the sum of the squares of its diagonals, provides a visual representation for the parallelogram identity that characterizes the norms of inner product spaces.

There is an abundant literature of geometric inequalities concerning important line segments in a triangle; see [Bottema et al. 1969; Mitrinović et al. 1989], for example. Some of these inequalities improve previously existing inequalities.

In this paper we present an application of the log-concavity of the Hölder mean with positive index, of two numbers, to find sharp inequalities relating lengths of cevians and sides of a triangle. Using these inequalities we find the best possible index for the Hölder mean, in a certain sense.

The paper is divided as follows:

In Section 2, we prove that the Hölder mean of two positive numbers, viewed as a function of its index, is logarithmically concave on  $[0, \infty)$ . In Section 3,

*Keywords:* Hölder mean, log-concavity, Jensen inequality, triangle, cevia.

we define the notion of an  $\alpha$ -cevia in a triangle, and find the smallest index  $p(\alpha)$  such that the length of every  $\alpha$ -cevia is less than or equal to the  $p(\alpha)$ -Hölder mean of the lengths of the two sides of the triangle that are adjacent to that cevia.

## 2. Log-concavity of Hölder means

Let  $a$  and  $b$  be two positive numbers. For any  $p \in [-\infty, \infty]$ , we define the  $p$ -Hölder mean of  $a$  and  $b$ , as

$$H_p(a, b) := \begin{cases} \left(\frac{1}{2}a^p + \frac{1}{2}b^p\right)^{1/p} & \text{if } p \in \mathbb{R} \setminus \{0\}, \\ \lim_{p \rightarrow 0} H_p(a, b) = \sqrt{ab} & \text{if } p = 0, \\ \lim_{p \rightarrow -\infty} H_p(a, b) = \min\{a, b\} & \text{if } p = -\infty, \\ \lim_{p \rightarrow \infty} H_p(a, b) = \max\{a, b\} & \text{if } p = \infty. \end{cases} \quad (2-1)$$

It follows from Jensen's inequality that for all  $-\infty \leq p < q \leq \infty$ , we have

$$H_p(a, b) \leq H_q(a, b), \quad (2-2)$$

and this inequality is strict if  $a \neq b$ ; see [Bullen 1998; Bullen et al. 1988; Pólya and Szegő 1972].

We prove now that the Hölder mean of two positive numbers, viewed as a function of its index, is logarithmically concave on  $[0, \infty)$ .

**Lemma 2.1.** *For all positive numbers  $a$  and  $b$ , the function  $f: [0, \infty) \rightarrow \mathbb{R}$ , defined by*

$$f(x) := \ln(H_x(a, b)), \quad (2-3)$$

*is concave downward.*

*Proof.* If  $a = b$ , then the lemma is obvious since  $f$  is a constant function, and its value is  $f(x) = \ln(a)$  for all  $x$  in  $[0, \infty)$ .

Let us assume now that  $0 < a < b$ . Then, defining  $c := \frac{b}{a} > 1$  for all  $x \geq 0$ , we have

$$f(x) = \ln(H_x(a, b)) = \ln\left(a H_x\left(1, \frac{b}{a}\right)\right) = \ln(H_x(1, c)) + \ln(a).$$

Thus the graph of  $f$  is just a vertical translation by  $\ln(a)$  of the graph of  $g: [0, \infty) \rightarrow \mathbb{R}$ , defined by

$$g(x) = \ln(H_x(1, c)). \quad (2-4)$$

Therefore, it suffices to show that  $g$  is concave downward on  $[0, \infty)$ .

We know that  $g$  is continuous on  $[0, \infty)$ , and so to achieve our goal we need to prove that the second derivative of  $g$  is negative on  $(0, \infty)$ .

Indeed, if  $'$  denotes the derivative with respect to  $x$ , then we have

$$\begin{aligned} g'(x) &= \frac{d}{dx} \left[ \frac{1}{x} \ln(1+c^x) - \frac{1}{x} \ln(2) \right] \\ &= -\frac{1}{x^2} \ln(1+c^x) + \frac{1}{x} \frac{c^x \ln(c)}{1+c^x} + \frac{\ln(2)}{x^2}. \end{aligned} \quad (2-5)$$

Differentiating one more time, we obtain

$$g''(x) = \frac{2}{x^3} \ln(1+c^x) - \frac{2}{x^2} \frac{c^x \ln(c)}{1+c^x} + \frac{1}{x} \frac{c^x \ln^2(c)}{(1+c^x)^2} - \frac{2 \ln(2)}{x^3}. \quad (2-6)$$

We make now the change of variable

$$y := c^x \in (1, \infty), \quad (2-7)$$

which means

$$x = \frac{\ln(y)}{\ln(c)}. \quad (2-8)$$

Substituting back in the formula of  $g''(x)$ , we obtain

$$g''(x) = \frac{2 \ln^3(c)}{\ln^3(y)} \ln(1+y) - \frac{2 \ln^2(c)}{\ln^2(y)} \frac{y \ln(c)}{1+y} + \frac{\ln(c)}{\ln(y)} \frac{y \ln^2(c)}{(1+y)^2} - \frac{2 \ln(2) \ln^3(c)}{\ln^3(y)}. \quad (2-9)$$

Thus, to show that, for all  $x > 0$ , we have  $g''(x) < 0$ , by multiplying both sides by the positive number  $(1+y)^2 \ln^3(y) / \ln^3(c)$ , we have to prove that for all  $y > 1$

$$h(y) := 2(1+y)^2 \ln(1+y) - 2y(1+y) \ln(y) + y \ln^2(y) - 2(1+y)^2 \ln(2) \quad (2-10)$$

is negative.

The function  $h$  is defined even for  $y = 1$ , and we have  $h(1) = 0$ .

We will study the sign of the first, second, and third derivatives of  $h$  on  $[1, \infty)$ .

Using the product rule of differentiation, the derivative of  $h$  with respect to  $y$  is

$$\begin{aligned} h'(y) &= 4(1+y) \ln(1+y) + 2(1+y)^2 \frac{1}{1+y} - 2(1+y) \ln(y) - 2y \ln(y) \\ &\quad - 2y(1+y) \frac{1}{y} + \ln^2(y) + 2y \ln(y) \frac{1}{y} - 4(1+y) \ln(2) \\ &= 4(1+y) \ln(1+y) - 4y \ln(y) + \ln^2(y) - 4(1+y) \ln(2). \end{aligned} \quad (2-11)$$

Let us observe that  $h'(1) = 0$ .

Differentiating again, we obtain

$$\begin{aligned} h''(y) &= 4 \ln(1+y) + 4(1+y) \frac{1}{1+y} - 4 \ln(y) - 4y \frac{1}{y} + 2 \frac{1}{y} \ln(y) - 4 \ln(2) \\ &= 4 \ln(1+y) - 4 \ln(y) + \frac{2 \ln(y)}{y} - 4 \ln(2). \end{aligned} \quad (2-12)$$

We observe that  $h''(1) = 0$ .

**Figure 1.** Graph of  $y = \ln[(1 + a^x)/2]^{1/x}$  for various values of  $a$ .

Finally, differentiating one more time, we obtain

$$h'''(y) = 2 \left[ \frac{2}{1+y} - \frac{2}{y} + \frac{1}{y^2} - \frac{\ln(y)}{y^2} \right] = 2 \left[ \frac{1-y}{y^2(y+1)} - \frac{\ln(y)}{y^2} \right] < 0 \quad (2-13)$$

for all  $y > 1$ , since  $1 - y < 0$  and  $-\ln(y) < 0$ .

Thus, we conclude that  $h''$  is strictly decreasing on  $[1, \infty)$ . This implies that for all  $y > 1$ , we have  $h''(y) < h''(1) = 0$ . Hence,  $h'$  is strictly decreasing on  $[1, \infty)$ . This implies that for all  $y > 1$ , we have  $h'(y) < h'(1) = 0$ . Therefore,  $h$  is strictly decreasing on  $[1, \infty)$ . Finally, from this assertion we conclude that  $h(y) < h(1) = 0$  for all  $y > 1$ . The last statement is equivalent to the fact that  $g''(x) < 0$  for all  $x > 0$ , and this proves that  $f$  is strictly concave on  $[0, \infty)$ . Therefore, the Hölder mean function of two positive, distinct numbers is strictly logarithmically concave downward on  $[0, \infty)$ .  $\square$

A graphical illustration of the logarithmic concavity of the Hölder means of two positive numbers 1 and  $a$ , for various values of  $a$ , is presented in Figure 1.

We make now the following simple observation.

**Observation 2.2.** The Hölder mean of two positive numbers is logarithmically symmetric about the geometric mean of the two numbers. That means, if  $a$  and  $b$  are positive numbers, then for all  $x \in [-\infty, \infty]$ , we have

$$H_x(a, b)H_{-x}(a, b) = H_0^2(a, b). \quad (2-14)$$

*Proof.* Indeed, if  $x = \infty$ , then

$$\begin{aligned} H_\infty(a, b)H_{-\infty}(a, b) &= \max\{a, b\} \min\{a, b\} \\ &= ab = H_0^2(a, b). \end{aligned}$$

On the other hand, for all  $x \in \mathbb{R} \setminus \{0\}$ , we have

$$\begin{aligned} H_x(a, b)H_{-x}(a, b) &= \left(\frac{a^x + b^x}{2}\right)^{1/x} \left(\frac{a^{-x} + b^{-x}}{2}\right)^{-1/x} \\ &= \frac{(a^x + b^x)^{1/x}}{2^{1/x}} \frac{(2a^x b^x)^{1/x}}{(a^x + b^x)^{1/x}} = ab = H_0^2(a, b). \quad \square \end{aligned}$$

**Corollary 2.3.** *Since for any two positive numbers  $a$  and  $b$ , the function  $x \mapsto \ln(H_x(a, b))$  is concave downward on  $[0, \infty)$ , and its graph is symmetric about the point  $(0, \ln(\sqrt{ab}))$ , this function is concave upward on  $(-\infty, 0]$ .*

### 3. Sharp inequalities concerning $\alpha$ -cevians in a triangle

In this section we use the logarithmic concavity property of the Hölder mean, of two positive numbers, as a function of the index, to prove a sharp inequality for the length of an  $\alpha$ -cevia in a triangle.

We give first some definitions.

**Definition 3.1.** Given a triangle  $ABC$  in the plane, for any point  $M$  on the side  $BC$ , we call  $AM$  a *cevia*.

If  $M \in BC$ , meaning  $M$  is between  $B$  and  $C$ , then we say that  $AM$  is an *interior* cevia.

We say that sides  $AB$  and  $AC$  of the triangle  $ABC$  are *adjacent* to the cevia  $AM$ .

**Definition 3.2.** Given a triangle  $ABC$  in the plane and  $\alpha$  a real number, if  $M_\alpha \in BC$ , then we say that  $AM_\alpha$  is an  $\alpha$ -*interior cevia* if

$$\frac{\overline{BM}_\alpha}{\overline{CM}_\alpha} = \left(\frac{\overline{AB}}{\overline{AC}}\right)^\alpha. \quad (3-1)$$

Here  $\overline{PQ}$  denotes the length of the segment  $PQ$  for any two points  $P$  and  $Q$  in the plane. See Figure 2.

**Observation 3.3.** For any real number  $\alpha$ , the three  $\alpha$ -interior cevians  $AM_\alpha$ ,  $BN_\alpha$ , and  $CP_\alpha$  of a triangle  $ABC$  are concurrent.

**Figure 2.** A triangle and its three  $\alpha$ -cevians.

*Proof.* Indeed, we have (see Figure 2)

$$\frac{\overline{BM}_\alpha}{\overline{CM}_\alpha} \cdot \frac{\overline{CN}_\alpha}{\overline{AN}_\alpha} \cdot \frac{\overline{AP}_\alpha}{\overline{BP}_\alpha} = \frac{\overline{AB}^\alpha}{\overline{AC}^\alpha} \cdot \frac{\overline{BC}^\alpha}{\overline{BA}^\alpha} \cdot \frac{\overline{CA}^\alpha}{\overline{CB}^\alpha} = 1.$$

It follows now from Ceva's theorem that  $AM_\alpha$ ,  $BN_\alpha$ , and  $CP_\alpha$  are concurrent.  $\square$

**Observation 3.4.** We make the following observations:

- For  $\alpha = 0$ ,  $AM_0$ ,  $BN_0$ , and  $CP_0$  are the medians of the triangle  $ABC$  and they are concurrent in the *centroid* of the triangle  $ABC$ . The centroid of a triangle is denoted by  $X(2)$  in [Kimberling 1994].
- For  $\alpha = 1$ ,  $AM_1$ ,  $BN_1$ , and  $CP_1$  are the inner bisectors of the angles of the triangle  $ABC$  and they are concurrent in the *incenter* of the triangle  $ABC$ . The incenter of a triangle is denoted by  $X(1)$  in [Kimberling 1994].
- For  $\alpha = 2$ ,  $AM_2$ ,  $BN_2$ , and  $CP_2$  are the symmedians (symmetric to the medians about the corresponding bisectors) of the triangle  $ABC$  and they are concurrent in the *Lemoine point*, also called the *Grebe point*, of the triangle  $ABC$ . The Lemoine (Grebe) point of a triangle is denoted by  $X(6)$  in [Kimberling 1994].

Let us observe that if  $AM$  is an interior cevian of a triangle  $ABC$ , then at least one of the angles  $\sphericalangle AMB$  and  $\sphericalangle AMC$  is obtuse or right. If the angle  $\sphericalangle AMB$  is obtuse or right, then in the triangle  $AMB$ , the side  $AB$  opposite to this angle, with say  $\overline{AB} = c$ , is the largest side of the triangle. Thus, we have  $\overline{AM} < c$ .

Similarly, if the angle  $\sphericalangle AMC$  is obtuse or right, then  $\overline{AM} < b$ .

Therefore, in both cases we conclude that

$$\overline{AM} < \max\{b, c\} = H_\infty(b, c).$$

Starting from this simple inequality, we can ask the question:

**Question 3.5.** Given a real number  $\alpha$ , what is the smallest number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all triangles  $ABC$ , if  $AM_\alpha$  is an  $\alpha$ -interior cevian, we have

$$\overline{AM}_\alpha \leq H_p(\overline{AB}, \overline{AC})? \quad (3-2)$$

We have the following proposition:

**Proposition 3.6.** Let  $b$  and  $c$  be two fixed positive numbers. We denote by  $\mathcal{T}_{b,c}$  the set of all triangles  $ABC$  in the plane such that  $\overline{AB} = c$  and  $\overline{AC} = b$ . Then, we have

$$\sup_{ABC \in \mathcal{T}_{b,c}} \{\overline{AM}_\alpha \mid AM_\alpha \text{ is an } \alpha\text{-interior cevian in } ABC\} = bc \frac{b^{\alpha-1} + c^{\alpha-1}}{b^\alpha + c^\alpha}. \quad (3-3)$$

*Proof.* We give a vectorial proof.

In triangle  $ABM_\alpha$  we have

$$\overrightarrow{AM}_\alpha = \overrightarrow{AB} + \overrightarrow{BM}_\alpha. \quad (3-4)$$

In triangle  $ACM_\alpha$  we have

$$\overrightarrow{AM_\alpha} = \overrightarrow{AC} + \overrightarrow{CM_\alpha}. \quad (3-5)$$

Let us first multiply both sides of (3-4) by  $b^\alpha$ , and both sides of (3-5) by  $c^\alpha$ , and then add the two resulting equations. We obtain

$$(b^\alpha + c^\alpha)\overrightarrow{AM_\alpha} = b^\alpha\overrightarrow{AB} + c^\alpha\overrightarrow{AC} + (b^\alpha\overrightarrow{BM_\alpha} + c^\alpha\overrightarrow{CM_\alpha}). \quad (3-6)$$

Since  $AM_\alpha$  is an  $\alpha$ -interior cevian, we have

$$\frac{\overrightarrow{BM_\alpha}}{\overrightarrow{CM_\alpha}} = \frac{c^\alpha}{b^\alpha}.$$

This is equivalent to

$$b^\alpha\overrightarrow{BM_\alpha} + c^\alpha\overrightarrow{CM_\alpha} = 0. \quad (3-7)$$

It follows now from (3-6) that

$$\overrightarrow{AM_\alpha} = \frac{1}{b^\alpha + c^\alpha}(b^\alpha\overrightarrow{AB} + c^\alpha\overrightarrow{AC}). \quad (3-8)$$

Applying the triangle inequality in (3-8), we conclude that

$$\begin{aligned} \overline{AM_\alpha} &\leq \frac{1}{b^\alpha + c^\alpha}(b^\alpha\overline{AB} + c^\alpha\overline{AC}) \\ &= \frac{1}{b^\alpha + c^\alpha}(b^\alpha c + c^\alpha b) = bc \frac{b^{\alpha-1} + c^{\alpha-1}}{b^\alpha + c^\alpha}. \end{aligned} \quad (3-9)$$

Since this happens for all triangles  $ABC$  such that  $\overline{AB} = c$  and  $\overline{AC} = b$ , we conclude that

$$S \leq bc \frac{b^{\alpha-1} + c^{\alpha-1}}{b^\alpha + c^\alpha}, \quad (3-10)$$

where

$$S = \sup_{ABC \in \mathcal{T}_{b,c}} \{\overline{AM_\alpha} \mid AM_\alpha \text{ is an } \alpha\text{-interior cevian in } ABC\}.$$

On the other hand, we have

$$\begin{aligned} S &\geq \lim_{m(\angle BAC) \rightarrow 0^+} \overline{AM_\alpha} \\ &= \lim_{m(\angle BAC) \rightarrow 0^+} \left[ \frac{1}{b^\alpha + c^\alpha} \left| b^\alpha\overrightarrow{AB} + c^\alpha\overrightarrow{AC} \right| \right] \\ &= \left[ \frac{1}{b^\alpha + c^\alpha} (b^\alpha\overline{AB} + c^\alpha\overline{AC}) \right] = bc \frac{b^{\alpha-1} + c^{\alpha-1}}{b^\alpha + c^\alpha}, \end{aligned} \quad (3-11)$$

where  $|\vec{v}|$  denotes the length of the vector  $\vec{v}$  for any vector  $\vec{v}$  in  $\mathbb{R}^2$ .

The result of our proposition follows now from inequalities (3-10) and (3-11).  $\square$

We can write

$$bc \frac{b^{\alpha-1} + c^{\alpha-1}}{b^\alpha + c^\alpha} = bc \frac{(b^{\alpha-1} + c^{\alpha-1})/2}{(b^\alpha + c^\alpha)/2} = H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)}. \quad (3-12)$$

Thus, we obtain

$$S = H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)}. \quad (3-13)$$

Now, Question 3.5 becomes:

**Question 3.7.** *Given a real number  $\alpha$ , what is the smallest number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all  $b$  and  $c$  positive, we have*

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} \leq H_p(b, c)? \quad (3-14)$$

Before answering this question, we present the following necessary condition for an inequality between two functions, whose graphs touch at one point, to hold.

**Lemma 3.8.** *Let  $I \subseteq \mathbb{R}$  be an interval, and let*

$$\overset{\circ}{I} := \{x \in I \mid \text{there exists } r > 0 \text{ such that } (x - r, x + r) \subset I\}$$

*be the set of the interior points of  $I$ . Suppose  $f$  and  $g$  are two real-valued functions such that:*

- (1)  $f(x) \leq g(x)$  for all  $x \in I$ .
- (2)  $f$  and  $g$  are continuous on  $I$ .
- (3)  $f$  and  $g$  are twice-differentiable on  $\overset{\circ}{I}$ .
- (4) There exists  $x_0 \in \overset{\circ}{I}$  such that  $f(x_0) = g(x_0)$ .
- (5)  $f''$  is continuous at  $x_0$ .

*Then, we must have  $f'(x_0) = g'(x_0)$  and  $f''(x_0) \leq g''(x_0)$ .*

*Proof.* Let  $h(x) := g(x) - f(x)$ . Then, for all  $x \in I$ , we have

$$h(x) \geq 0 = h(x_0).$$

Thus,  $h$  has an absolute minimum value at  $x_0$ , and since  $x_0$  is a point in the interior of  $I$ , Fermat's theorem implies  $h'(x_0) = 0$ . This is equivalent to  $f'(x_0) = g'(x_0)$ .

Since  $x_0 \in \overset{\circ}{I}$ , there exists  $r > 0$  such that  $(x_0 - r, x_0 + r) \subset I$ . Because the function  $f$  is dominated by function  $g$ , for all  $0 < h < r$ , we have

$$\begin{aligned} f(x_0 + h) &\leq g(x_0 + h), \\ f(x_0 - h) &\leq g(x_0 - h), \\ -2f(x_0) &= -2g(x_0). \end{aligned}$$

Adding these three relations and dividing both sides by the positive number  $h^2$ , we obtain

$$\frac{f(x_0 + h) + f(x_0 - h) - 2f(x_0)}{h^2} \leq \frac{g(x_0 + h) + g(x_0 - h) - 2g(x_0)}{h^2}.$$

Passing to the limit as  $h \rightarrow 0^+$ , we obtain

$$\lim_{h \rightarrow 0^+} \frac{f(x_0 + h) + f(x_0 - h) - 2f(x_0)}{h^2} \leq \lim_{h \rightarrow 0^+} \frac{g(x_0 + h) + g(x_0 - h) - 2g(x_0)}{h^2}. \quad (3-15)$$

Applying L'Hôpital's rule in the  $\frac{0}{0}$  case, twice, or using Taylor's formula with Lagrange's remainder, it is not hard to see that due to the continuity of  $f''$  at  $x_0$ , the last inequality becomes

$$f''(x_0) \leq g''(x_0). \quad \square$$

To answer Question 3.7, we will analyze four cases.

**Case 1.** If  $\alpha \geq 1$ , then the answer of Question 3.7 is given by the following proposition.

**Proposition 3.9.** *If  $\alpha \geq 1$ , then the smallest number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all positive numbers  $b$  and  $c$ , we have*

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha(b, c)} \leq H_p(b, c) \quad (3-16)$$

is

$$p(\alpha) = 1 - 2\alpha. \quad (3-17)$$

*Proof.* Step 1: We prove first the inequality  $p(\alpha) \leq 1 - 2\alpha$ .

Indeed, using Observation 2.2, we have

$$\begin{aligned} H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha(b, c)} &= (H_{1-2\alpha}(b, c) H_{2\alpha-1}(b, c)) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha(b, c)} \\ &= H_{1-2\alpha}(b, c) \left[ \frac{H_{\alpha-1}^{(\alpha-1)/\alpha}(b, c) H_{2\alpha-1}^{1/\alpha}(b, c)}{H_\alpha(b, c)} \right]^\alpha \\ &\leq H_{1-2\alpha}(b, c) \cdot 1^\alpha = H_{1-2\alpha}(b, c), \end{aligned} \quad (3-18)$$

since  $0 \leq \alpha - 1 < \alpha \leq 2\alpha - 1$  (due to the fact that  $\alpha \geq 1$ ),

$$\frac{\alpha - 1}{\alpha}(\alpha - 1) + \frac{1}{\alpha}(2\alpha - 1) = \alpha, \quad (3-19)$$

and so, because  $x \mapsto H_x(b, c)$  is logarithmically concave on  $[0, \infty)$ , we have

$$H_{\alpha-1}^{(\alpha-1)/\alpha}(b, c) H_{2\alpha-1}^{1/\alpha}(b, c) \leq H_\alpha(b, c). \quad (3-20)$$

Step 2: We prove now that if  $p$  is a positive number such that for all positive numbers  $b$  and  $c$ , we have

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} \leq H_p(b, c),$$

then  $p \geq 1 - 2\alpha$ .

Choosing  $b = 1$  and  $c = x$ , where  $x$  is an arbitrary positive number, the above inequality becomes

$$x \frac{1 + x^{\alpha-1}}{1 + x^\alpha} \leq \left( \frac{1 + x^p}{2} \right)^{1/p}. \quad (3-21)$$

We can see now that the hypotheses of Lemma 3.8 are satisfied for the functions

$$f(x) := \frac{x + x^\alpha}{1 + x^\alpha} = 1 + \frac{x - 1}{1 + x^\alpha} = 1 + \frac{1}{2}(x - 1) + (x - 1) \left( \frac{1}{1 + x^\alpha} - \frac{1}{2} \right) \quad (3-22)$$

and

$$g(x) := \left( \frac{1 + x^p}{2} \right)^{1/p}, \quad (3-23)$$

and the point

$$x_0 := 1. \quad (3-24)$$

Thus, we obtain

$$f''(1) \leq g''(1). \quad (3-25)$$

Using Leibniz's rule of differentiation and keeping only the nonzero terms, we obtain

$$\begin{aligned} f''(1) &= \frac{d^2}{dx^2} \left[ 1 + \frac{1}{2}(x - 1) + (x - 1) \left( \frac{1}{1 + x^\alpha} - \frac{1}{2} \right) \right] \Big|_{x=1} \\ &= \frac{d^2}{dx^2} \left[ (x - 1) \left( \frac{1}{1 + x^\alpha} - \frac{1}{2} \right) \right] \Big|_{x=1} \\ &= \binom{2}{1} \frac{d}{dx} (x - 1) \Big|_{x=1} \frac{d}{dx} \left( \frac{1}{1 + x^\alpha} - \frac{1}{2} \right) \Big|_{x=1} \\ &= 2 \left( \frac{-\alpha x^{\alpha-1}}{(1 + x^\alpha)^2} \right) \Big|_{x=1} = -\frac{\alpha}{2}. \end{aligned} \quad (3-26)$$

On the other hand, we have

$$\begin{aligned} g'(x) &= \frac{1}{2^{1/p}} \frac{d}{dx} [(1 + x^p)^{1/p}] \\ &= \frac{1}{2^{1/p}} \frac{1}{p} (1 + x^p)^{(1/p)-1} p x^{p-1} \\ &= \frac{1}{2^{1/p}} \left( \frac{1 + x^p}{x^p} \right)^{(1-p)/p} = \frac{1}{2^{1/p}} (x^{-p} + 1)^{(1-p)/p}. \end{aligned}$$

Thus, we obtain

$$\begin{aligned} g''(x) &= \frac{1}{2^{1/p}} \frac{1-p}{p} (x^{-p} + 1)^{(1-2p)/p} (-p)x^{-p-1} \\ &= \frac{p-1}{2^{1/p}} (x^{-p} + 1)^{(1-2p)/p} x^{-p-1}. \end{aligned}$$

Hence, we have

$$g''(1) = \frac{p-1}{4}. \quad (3-27)$$

Therefore, inequality (3-25) becomes

$$-\frac{\alpha}{2} \leq \frac{p-1}{4}. \quad (3-28)$$

This inequality is equivalent to

$$p \geq 1 - 2\alpha, \quad (3-29)$$

and so, our proof is complete.  $\square$

**Case 2.** If  $\frac{1}{2} < \alpha < 1$ , then the answer to Question 3.7 is given by the following proposition.

**Proposition 3.10.** *If  $\frac{1}{2} < \alpha < 1$ , then the smallest number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all positive numbers  $b$  and  $c$ , we have*

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_{\alpha}^{\alpha}(b, c)} \leq H_p(b, c)$$

is

$$p(\alpha) = 0. \quad (3-30)$$

*Proof.* Step 1: We prove first the inequality  $p(\alpha) \leq 0$ . That means, we show that for all positive numbers  $b$  and  $c$  we have

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_{\alpha}^{\alpha}(b, c)} \leq H_0(b, c).$$

Indeed, using the symmetry of the function  $x \mapsto \ln(H_x(b, c))$  with respect to the origin

$$H_x(b, c)H_{-x}(b, c) = H_0^2(b, c), \quad (3-31)$$

for  $x = \alpha - 1$ , we obtain

$$H_{\alpha-1}(b, c) = \frac{H_0^2(b, c)}{H_{1-\alpha}(b, c)}. \quad (3-32)$$

Thus, we have

$$\begin{aligned}
 H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} &= H_0^2(b, c) \left[ \frac{H_0^2(b, c)}{H_{1-\alpha}(b, c)} \right]^{\alpha-1} \frac{1}{H_\alpha^\alpha(b, c)} \\
 &= \frac{H_0^{2\alpha}(b, c) H_{1-\alpha}^{1-\alpha}(b, c)}{H_\alpha^\alpha(b, c)} \\
 &= H_0(b, c) \left[ \frac{H_0(b, c)}{H_\alpha(b, c)} \right]^{2\alpha-1} \left[ \frac{H_{1-\alpha}(b, c)}{H_\alpha(b, c)} \right]^{1-\alpha} \\
 &\leq H_0(b, c) \cdot 1^{2\alpha-1} \cdot 1^{1-\alpha} = H_0(b, c), \tag{3-33}
 \end{aligned}$$

since  $0 < \alpha$ ,  $1 - \alpha < \alpha$ , the function  $x \mapsto H_x(b, c)$  is increasing,  $2\alpha - 1 > 0$ , and  $1 - \alpha > 0$ .

Step 2: We show now that if  $p < 0$ , then the inequality

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} \leq H_p(b, c)$$

cannot hold for all positive numbers  $b$  and  $c$ .

Indeed, if we assume by contradiction that it holds for all positive numbers  $b$  and  $c$ , then choosing  $b = 1$  and  $c = x$ , where  $x$  is an arbitrary positive number, we obtain

$$x \frac{1 + x^{\alpha-1}}{1 + x^\alpha} \leq \left( \frac{1 + x^p}{2} \right)^{1/p}. \tag{3-34}$$

Passing to the limit as  $x \rightarrow \infty$ , we get

$$\lim_{x \rightarrow \infty} \frac{x + x^\alpha}{1 + x^\alpha} \leq \lim_{x \rightarrow \infty} \left( \frac{1 + x^p}{2} \right)^{1/p}. \tag{3-35}$$

Since  $\alpha < 1$  and  $p < 0$ , the last inequality becomes

$$\infty \leq \left( \frac{1}{2} \right)^{1/p},$$

which is a contradiction.

Thus the smallest number  $p$  for which inequality (3-14) holds is  $p(\alpha) = 0$ .  $\square$

**Case 3.** If  $0 \leq \alpha \leq \frac{1}{2}$ , then the answer to Question 3.7 is given by the following proposition.

**Proposition 3.11.** *If  $0 \leq \alpha \leq 1$ , then the smallest number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all positive numbers  $b$  and  $c$  we have*

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} \leq H_p(b, c)$$

is

$$p(\alpha) = 1 - 2\alpha. \tag{3-36}$$

*Proof. Step 1:* We show first that  $p(\alpha) \leq 1 - 2\alpha$ . Using the logarithmic symmetry of the function  $x \mapsto H_x(b, c)$ , we have

$$\begin{aligned} H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} &= H_0^2(b, c) \left[ \frac{H_0^2(b, c)}{H_{1-\alpha}(b, c)} \right]^{\alpha-1} \frac{1}{H_\alpha^\alpha(b, c)} \\ &= \frac{H_0^{2\alpha}(b, c) H_{1-\alpha}^{1-\alpha}(b, c)}{H_\alpha^\alpha(b, c)}. \end{aligned} \quad (3-37)$$

Since  $0 \leq \alpha \leq \frac{1}{2}$ , we have  $0 \leq \alpha \leq 1 - \alpha$ , and  $\alpha$  can be written as a convex combination of 0 and  $1 - \alpha$  in the following way:

$$\alpha = \left(1 - \frac{\alpha}{1 - \alpha}\right) \cdot 0 + \frac{\alpha}{1 - \alpha} \cdot (1 - \alpha). \quad (3-38)$$

Since  $x \mapsto H_x(b, c)$  is logarithmically concave on  $[0, \infty)$ , applying Jensen's inequality, we obtain

$$H_\alpha \geq H_0^{1-\alpha/(1-\alpha)} H_{1-\alpha}^{\alpha/(1-\alpha)}. \quad (3-39)$$

Thus, using (3-37) and (3-39), we have

$$\begin{aligned} H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} &= \frac{H_0^{2\alpha}(b, c) H_{1-\alpha}^{1-\alpha}(b, c)}{H_\alpha^\alpha(b, c)} \\ &\leq \frac{H_0^{2\alpha}(b, c) H_{1-\alpha}^{1-\alpha}(b, c)}{[H_0^{1-\alpha/(1-\alpha)}(b, c) H_{1-\alpha}^{\alpha/(1-\alpha)}(b, c)]^\alpha} \\ &= H_0^{\alpha/(1-\alpha)}(b, c) H_{1-\alpha}^{(1-2\alpha)/(1-\alpha)}(b, c). \end{aligned} \quad (3-40)$$

Let us observe that  $\alpha/(1 - \alpha) \in [0, 1]$ ,  $(1 - 2\alpha)/(1 - \alpha) \in [0, 1]$ , and

$$\frac{\alpha}{1 - \alpha} + \frac{1 - 2\alpha}{1 - \alpha} = 1. \quad (3-41)$$

Applying, Jensen's inequality again, we obtain

$$\begin{aligned} H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} &\leq H_0^{\alpha/(1-\alpha)}(b, c) H_{1-\alpha}^{(1-2\alpha)/(1-\alpha)}(b, c) \\ &\leq H_{[\alpha/(1-\alpha)] \cdot 0 + [(1-2\alpha)/(1-\alpha)] \cdot (1-\alpha)}(b, c) \\ &= H_{1-2\alpha}(b, c). \end{aligned} \quad (3-42)$$

Step 2: We can prove now in exactly the same way as in the proof of Proposition 3.9 that if  $p$  is real number such that inequality (3-14) holds for all positive numbers  $b$  and  $c$ , then

$$p \geq 1 - 2\alpha. \quad \square$$

**Case 4.** If  $\alpha < 0$ , then the answer to Question 3.7 is given by the following proposition.

**Proposition 3.12.** *If  $\alpha < 0$ , then the smallest (only) number  $p = p(\alpha) \in [-\infty, \infty]$  such that for all positive numbers  $b$  and  $c$ , we have*

$$H_0^2(b, c) \frac{H_{\alpha-1}^{\alpha-1}(b, c)}{H_\alpha^\alpha(b, c)} \leq H_p(b, c)$$

is

$$p(\alpha) = \infty. \quad (3-43)$$

*Proof.* Indeed, we saw geometrically at the beginning of the paper that for all triangles  $ABC$ , and all interior cevians  $AM$ , we have

$$\overline{AM} \leq \max\{\overline{AB}, \overline{AC}\} = H_\infty(b, c),$$

where  $b := \overline{AC}$  and  $c := \overline{AB}$ .

To show that  $p(\alpha) = \infty$ , we must prove that for all  $p < \infty$ , inequality (3-14) cannot hold for all positive numbers  $b$  and  $c$ .

Supposing that for some  $p < \infty$  (we may assume  $p > 0$ ) inequality (3-14) holds for all positive numbers  $b$  and  $c$ , we can choose  $b = 1$  and  $c = x$ , where  $x$  is an arbitrary positive number. That means, for all  $x > 0$ , we have

$$\frac{x + x^\alpha}{1 + x^\alpha} \leq \left( \frac{1 + x^p}{2} \right)^{1/p}.$$

Passing to the limit in this inequality as  $x \rightarrow 0^+$ , we obtain

$$\lim_{x \rightarrow 0^+} \frac{x + x^\alpha}{1 + x^\alpha} \leq \lim_{x \rightarrow 0^+} \left( \frac{1 + x^p}{2} \right)^{1/p}.$$

Since  $\alpha < 0$ , the last inequality is equivalent to

$$1 \leq \left( \frac{1}{2} \right)^{1/p}.$$

This inequality is impossible, since  $0 < \frac{1}{2} < 1$  and  $\frac{1}{p} > 0$ . □

Therefore, the function  $\alpha \mapsto p(\alpha)$  that gives the smallest  $p$  such that in any triangle  $ABC$  the  $\alpha$ -interior cevian starting from  $A$ ,  $AM_\alpha$ , has a length less than or equal to the  $p$ -Hölder mean of  $\overline{AB}$  and  $\overline{AC}$  is  $P : \mathbb{R} \rightarrow [-\infty, \infty]$ , defined by

$$P(\alpha) = \begin{cases} \infty & \text{if } \alpha < 0, \\ 1 - 2\alpha & \text{if } 0 \leq \alpha \leq \frac{1}{2}, \\ 0 & \text{if } \frac{1}{2} < \alpha < 1, \\ 1 - 2\alpha & \text{if } \alpha > 1. \end{cases} \quad (3-44)$$

See the graph of  $P$  in Figure 3.

**Figure 3.** The graph of function  $y = P(\alpha)$ .

We observe that the function  $P$  is nonincreasing and lower semicontinuous.

The branching point  $\alpha = 0$  of the piecewise-defined function  $P$  corresponds to the median  $AM_0$  of the triangle  $ABC$ .

The branching point  $\alpha = 1$  corresponds to the bisector  $AM_1$  of the angle  $\sphericalangle BAC$ .

The branching point  $\alpha = \frac{1}{2}$  corresponds to a cevian  $AM_{1/2}$  that is concurrent with the corresponding cevians  $BN_{1/2}$  and  $CP_{1/2}$  in the point  $X(366)$  from [Kimberling 1994]. The point  $X(366)$  is the isogonal conjugate of  $X(365)$ , the square root point, which is the intersection point of the three  $\frac{3}{2}$ -interior cevians of the triangle  $ABC$ .

We summarize below our results, in the case of some classic cevians:

**Proposition 3.13.** *Let  $ABC$  be a triangle with sides, starting from  $A$ , of lengths  $\overline{AC} = b$  and  $\overline{AB} = c$ . Let  $M$  be a point on the side  $BC$  of this triangle. Then:*

(1) *If  $AM$  is the median corresponding to the vertex  $A$ , then its length satisfies*

$$\overline{AM} < \frac{b+c}{2}. \quad (3-45)$$

*Moreover, for every  $p < 1$ , there exists a triangle  $ABC$  (depending on  $p$ ) such that*

$$\overline{AM} > \left( \frac{b^p + c^p}{2} \right)^{1/p}. \quad (3-46)$$

(2) *If  $AM$  is the interior bisector of the angle  $\sphericalangle(BAC)$ , then its length satisfies*

$$\overline{AM} < \frac{2}{\frac{1}{a} + \frac{1}{b}}. \quad (3-47)$$

*Moreover, for every  $p < -1$ , there exists a triangle  $ABC$  such that*

$$\overline{AM} > \left( \frac{b^p + c^p}{2} \right)^{1/p}. \quad (3-48)$$

(3) If  $AM$  is the symmedian corresponding to the vertex  $A$ , then its length satisfies

$$\overline{AM} < \left( \frac{b^{-3} + c^{-3}}{2} \right)^{-1/3}. \quad (3-49)$$

Moreover, for every  $p < -3$ , there exists a triangle  $ABC$  such that

$$\overline{AM} > \left( \frac{b^p + c^p}{2} \right)^{1/p}. \quad (3-50)$$

### Acknowledgements

This research was carried out during the Sampling Advanced Mathematics for Minority Students (SAMMS) program, organized by The Ohio State University (OSU), Department of Mathematics, in Columbus, Ohio, July 10–August 4, 2017. The authors would like to express their gratitude to the OSU Department of Mathematics for supporting this research.

The authors would also like to thank Professor Clark Kimberling, from the University of Evansville, Indiana, for providing them the necessary information about the point  $X(366)$ .

The authors are extremely grateful to Professor Edward Overman, from the OSU Department of Mathematics for greatly helping them with the figures for this paper.

## INVOLVE YOUR STUDENTS IN RESEARCH

*Involve* showcases and encourages high-quality mathematical research involving students from all academic levels. The editorial board consists of mathematical scientists committed to nurturing student participation in research. Bridging the gap between the extremes of purely undergraduate research journals and mainstream research journals, *Involve* provides a venue to mathematicians wishing to encourage the creative involvement of students.
