Local rings of embedding codepth 3:
A classification algorithm

LARS WINTHER CHRISTENSEN AND OANA VELICHE

Abstract: Let $I$ be an ideal of a regular local ring $Q$ with residue field $k$. The length of the minimal free resolution of $R = Q/I$ is called the codepth of $R$. If it is at most 3, then the resolution carries the structure of a differential graded algebra, and the induced algebra structure on $\text{Tor}^Q_\ast(R, k)$ provides for a classification of such local rings.

We describe the Macaulay2 package CodepthThree that implements an algorithm for classifying a local ring as above by computation of a few cohomological invariants.

Introduction and Notation. Let $R$ be a commutative noetherian local ring with residue field $k$. Assume that $R$ has the form $Q/I$, where $Q$ is a regular local ring with maximal ideal $n$ and $I \subseteq n^2$. The embedding dimension of $R$ (and of $Q$) is denoted $e$. Let

$$F = 0 \longrightarrow F_c \longrightarrow \cdots \longrightarrow F_1 \longrightarrow F_0 \longrightarrow 0$$

be a minimal free resolution of $R$ over $Q$. Set $d = \text{depth } R$; the length $c$ of the resolution $F$ is

$$c = \text{proj.dim}_Q R = \text{depth } Q - \text{depth}_Q R = e - d,$$

by the Auslander–Buchsbaum formula, and one refers to this invariant as the codepth of $R$. In the following we assume that $c$ is at most 3. By a theorem of Buchsbaum and Eisenbud [Bruns and Herzog 1993, 3.4.3] the resolution $F$ carries a differential graded algebra structure, which induces a unique graded-commutative algebra structure on $A = \text{Tor}^Q_\ast(R, k)$. The possible structures were identified by Weyman [1989] and by Avramov, Kustin, and Miller [Avramov et al. 1988]. According to the multiplicative structure on $A$, the ring $R$ belongs to exactly one of
the classes designated \( B, C(c), G(r), H(p, q), S, \) and \( T. \) Here the parameters \( p, q, \) and \( r \) are given by

\[
p = \text{rank}_k (A_1 \cdot A_1), \quad q = \text{rank}_k (A_1 \cdot A_2), \quad r = \text{rank}_k (\delta : A_2 \to \text{Hom}_k (A_1, A_3)),
\]

where \( \delta \) is the canonical map. See [Avramov 2012; Avramov et al. 1988; Weyman 1989] for further background and details.

When, in the following, we talk about classification of a local ring \( R, \) we mean the classification according to the multiplicative structure on \( A. \) To describe the classification algorithm, we need a few more invariants of \( R. \) Set

\[
l = \text{rank}_Q F_1 - 1 \quad \text{and} \quad n = \text{rank}_Q F_c;
\]

the latter invariant is called the type of \( R. \) The Cohen–Macaulay defect of \( R \) is \( h = \dim R - d. \) The Betti numbers \( \beta_i \) and the Bass numbers \( \mu_i \) record ranks of cohomology groups:

\[
\beta_i = \beta_i^R (k) = \text{rank}_k \text{Ext}_R^i (k, k) \quad \text{and} \quad \mu_i = \mu_i (R) = \text{rank}_k \text{Ext}_R^i (k, R).
\]

The generating functions \( \sum_{i=0}^{\infty} \beta_i t^i \) and \( \sum_{i=0}^{\infty} \mu_i t^i \) are called the Poincaré series and the Bass series of \( R. \)

**The Algorithm.** For a local ring of codepth \( c \leq 3, \) the class together with the invariants \( e, c, l, \) and \( n \) completely determine the Poincaré series and Bass series of \( R; \) see [Avramov 2012]. Conversely, one can determine the class of \( R \) based on \( e, c, l, n, \) and a few Betti and Bass numbers; in the following we describe how.

**Lemma 1.** For a local ring \( R \) of codepth 3 the invariants \( p, q, \) and \( r \) are determined by \( e, l, n, \beta_2, \beta_3, \beta_4, \) and \( \mu_{e-2} \) through the formulas

\[
p = n + le + \beta_2 - \beta_3 + \binom{e-1}{3},
q = (n - p)e + l\beta_2 + \beta_3 - \beta_4 + \binom{e-1}{4},
r = l + n - \mu_{e-2}.
\]

**Proof.** The Poincaré series of \( R \) has the form

\[
\sum_{i=0}^{\infty} \beta_i t^i = \frac{(1 + t)^{e-1}}{1 - t - lt^2 - (n - p)t^3 + qt^4 + \cdots}
\]

by [Avramov 2012, 2.1], and expansion of the rational function yields the expressions for \( p \) and \( q. \)
One has $d = e - 3$ and the Bass series of $R$ has, also by [Avramov 2012, 2.1], the form

$$\sum_{i=0}^{\infty} \mu_i t^i = \frac{t^d n + (l - r)t + \cdots}{1 - t + \cdots};$$

(2)

expansion of the rational function now yields the expression for $r$. \hfill \square

**Proposition 2.** A local ring $R$ of codepth 3 can be classified based on the invariants $e, h, l, n, \beta_2, \beta_3, \beta_4, \mu_{e-2}$, and $\mu_{e-1}$.

**Proof.** First recall that one has $h = 0$ and $n = 1$ if and only if $R$ is Gorenstein; see [Bruns and Herzog 1993, 3.2.10]. In this case $R$ is in class $C(3)$ if $l = 2$ and otherwise in the class $G(l + 1)$.

Assume now that $R$ is not Gorenstein. The invariants $p, q,$ and $r$ can be computed from the formulas in Lemma 1. It remains to determine the class, which can be done by case analysis. Recall from [Avramov 2012, 1.3 and 3.1] that one has

<table>
<thead>
<tr>
<th>Class</th>
<th>$p$</th>
<th>$q$</th>
<th>$r$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T$</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$B$</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>$G(r)$ $[r \geq 2]$</td>
<td>0</td>
<td>1</td>
<td>$r$</td>
</tr>
<tr>
<td>$H(p, q)$</td>
<td>$p$</td>
<td>$q$</td>
<td>$q$</td>
</tr>
</tbody>
</table>

In case $q \geq 2$, the ring $R$ is in class $H(p, q)$; for $q \leq 1$ the case analysis shifts to $p$.

In case $p = 0$, the distinction between the classes $G(r)$ and $H(0, q)$ is made by comparing $q$ and $r$; they are equal if and only if $R$ is in class $H(0, q)$.

In case $p = 1$, the distinction between the classes $B$ and $H(1, q)$ is made by comparing $q$ and $r$; they are equal if and only if $R$ is in class $H(1, q)$.

In case $p = 3$, the distinction between the classes $T$ and $H(3, q)$ is drawn by the invariant $\mu_{e-1}$. Recall the relation $d = e - 3$; expansion of the expressions from [Avramov 2012, 2.1] yields $\mu_{e-1} = \mu_{e-2} + ln - 2$ if $R$ is in $T$ and $\mu_{e-1} = \mu_{e-2} + ln - 3$ if $R$ is in $H(3, q)$.

In all other cases, i.e., $p = 2$ or $p \geq 4$, the ring $R$ is in class $H(p, q)$. \hfill \square

**Remark 3.** One can also classify a local ring $R$ of codepth 3 based on the invariants $e, h, l, n, \beta_2, \ldots, \beta_5,$ and $\mu_{e-2}$. In the case $p = 3$ one then discriminates between the classes by looking at $\beta_5$, which is $\beta_4 + 1\beta_3 + (n - 3)\beta_2 + \tau$, with $\tau = 0$ if $R$ is in class $H(3, q)$ and $\tau = 1$ if $R$ is in class $T$. However, it is not possible to classify $R$ based on Betti numbers alone. Indeed, rings in the classes $B$ and $H(1, 1)$ have identical Poincaré series and so do rings in the classes $G(r)$ and $H(0, 1)$. 
**Remark 4.** A local ring $R$ of codepth $c \leq 2$ can be classified based on the invariants $c$, $h$, and $n$. Indeed, if $c \leq 1$ then $R$ is a hypersurface; i.e., it belongs to class $C(c)$. If $c = 2$ then $R$ belongs to class $C(2)$ if and only if it is Gorenstein ($h = 0$ and $n = 1$); otherwise it belongs to class $S$.

**Algorithm 5.** From Remark 4 and the proof of Proposition 2, one gets the following algorithm that takes as input invariants of a local ring of codepth $c \leq 3$ and outputs its class.

**Input:** $c$, $e$, $h$, $l$, $n$, $\beta_2$, $\beta_3$, $\beta_4$, $\mu_{e-2}$, $\mu_{e-1}$.

- In case $c \leq 1$, set $\text{Class} = C(c)$.
- In case $c = 2$,
  - if ($h = 0$ and $n = 1$) then set $\text{Class} = C(2)$,
  - else set $\text{Class} = S$.
- In case $c = 3$,
  - if ($h = 0$ and $n = 1$) then set $r = l + 1$,
    - if $r = 3$: then set $\text{Class} = C(3)$,
    - else set $\text{Class} = G(r)$;
  - else compute $p$ and $q$:
    - if ($q \geq 2$ or $p = 2$ or $p \geq 4$) then set $\text{Class} = H(p, q)$,
    - else compute $r$:
      - In case $p = 0$,
        - if $q = r$ then set $\text{Class} = H(0, q)$,
        - else set $\text{Class} = G(r)$.
      - In case $p = 1$,
        - if $q = r$ then set $\text{Class} = H(1, q)$,
        - else set $\text{Class} = B$.
      - In case $p = 3$,
        - if $\mu_{e-1} = \mu_{e-2} + ln - 2$ then set $\text{Class} = T$,
        - else set $\text{Class} = H(3, q)$.

**Output:** $\text{Class}$

**Remark 6.** Given a local ring $R = Q/I$ the invariants $e$ and $h$ can be computed from $R$, and $c$, $l$, and $n$ can be determined by computing a minimal free resolution of $R$ over $Q$. The Betti numbers $\beta_2$, $\beta_3$, $\beta_4$ one can get by computing the first five steps of a minimal free resolution $F$ of $k$ over $R$. Recall the relation $d = e - c$; the Bass numbers $\mu_{e-2}$ and $\mu_{e-1}$ one can get by computing the cohomology in degrees $d + 1$ and $d + 2$ of the dual complex $F^* = \text{Hom}_R(F, R)$. For large values of $d$, this may not be feasible, but one can reduce $R$ modulo a regular sequence $x = x_1, \ldots, x_d$ and obtain the Bass numbers as $\mu_{d+i}(R) = \mu_i(R/(x))$; see [Bruns and Herzog 1993, 3.1.16].
THE IMPLEMENTATION. The Macaulay2 package CodepthThree implements Algorithm 5. The function torAlgClass takes as input a quotient $Q/I$ of a polynomial algebra, where $I$ is contained in the irrelevant maximal ideal $\mathfrak{N}$ of $Q$. It returns the class of the local ring $R$ obtained by localization of $Q/I$ at $\mathfrak{N}$. For example, the local ring obtained by localizing the quotient

$$\mathbb{Q}[x, y, z]/(xy^2, xyz, yz^2, x^4 - y^3z, xz^3 - y^4)$$

is in class $G(2)$; see [Christensen and Veliche 2014]. Here is how it looks when one calls the function torAlgClass.

Macaulay2, version 1.6
with packages: ConwayPolynomials, Elimination, IntegralClosure, LLLBases, PrimaryDecomposition, ReesAlgebra, TangentCone

i1 : needsPackage "CodepthThree";
i2 : Q = QQ[x,y,z];
i3 : I = ideal (x*y^2, x*y*z, y*z^2, x^4-y^3*z, x*z^3-y^4);
o3 : Ideal of Q
i4 : torAlgClass (Q/I)
o4 = G(2)

Underlying torAlgClass is the workhorse function torAlgData, which returns a hash table with the following data:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;c&quot;</td>
<td>codepth of $R$</td>
</tr>
<tr>
<td>&quot;e&quot;</td>
<td>embedding dimension of $R$</td>
</tr>
<tr>
<td>&quot;h&quot;</td>
<td>Cohen–Macaulay defect of $R$</td>
</tr>
<tr>
<td>&quot;m&quot;</td>
<td>minimal number of generators of defining ideal of $R$</td>
</tr>
<tr>
<td>&quot;n&quot;</td>
<td>type of $R$</td>
</tr>
<tr>
<td>&quot;Class&quot;</td>
<td>(nonparametrized) class of $R$</td>
</tr>
<tr>
<td>&quot;p&quot;</td>
<td>rank of $A_1 \cdot A_1$</td>
</tr>
<tr>
<td>&quot;q&quot;</td>
<td>rank of $A_1 \cdot A_2$</td>
</tr>
<tr>
<td>&quot;r&quot;</td>
<td>rank of $\delta: A_2 \rightarrow \text{Hom}_k(A_1, A_3)$</td>
</tr>
<tr>
<td>&quot;PoincareSeries&quot;</td>
<td>Poincaré series of $R$</td>
</tr>
<tr>
<td>&quot;BassSeries&quot;</td>
<td>Bass series of $R$</td>
</tr>
</tbody>
</table>

In the example from above one gets:

i5 : torAlgData(Q/I)

\[
\begin{align*}
2 & 3 & 4 \\
2 & + & 2T & - & T & - & T & + & T \\
1 & - & T & - & 4T & - & 2T & + & T \\
\end{align*}
\]

c => 3
To facilitate extraction of data from the hash table, the package offers two functions \texttt{torAlgDataList} and \texttt{torAlgDataPrint} that take as input a quotient ring and a list of keys. In the example from above one gets:

\begin{verbatim}
 i6 : torAlgDataList( Q/I,  
    {"c", "Class", "p", "q", "r", "PoincareSeries"} )  
2    
 o6 = {3, G, 0, 1, 2, ----------------------}  
 2 3 4  
    1 - T - 4T - 2T + T
\end{verbatim}

\begin{verbatim}
o6 : List
 i7 : torAlgDataPrint( Q/I, {"e", "h", "m", "n", "r"} )  
    e=3 h=1 m=5 n=2 r=2
\end{verbatim}

As discussed in Remark 6, the computation of Bass numbers may require a reduction modulo a regular sequence. In our implementation such a reduction is attempted if the embedding dimension of the local ring $R$ is more than 3. The procedure involves random choices of ring elements, and hence it may fail. By default, up to 625 attempts are made, and one can change the number of attempts with the function \texttt{setAttemptsAtGenericReduction}. If none of the attempts are successful, then an error message is displayed:

\begin{verbatim}
i8 : Q = ZZ/2[u,v,w,x,y,z];
i9 : R = Q/ideal(x*y^2,x*y*z,y*z^2,x^4-y^3*z,x*z^3-y^4);
i10 : setAttemptsAtGenericReduction(R,1)
o10 = 1 attempt(s) will be made to compute the Bass numbers via a generic reduction
\end{verbatim}
i11 : torAlgClass R
stdio:11:1:(3): error: Failed to compute Bass numbers. You may raise
the number of attempts to compute Bass numbers via a
generic reduction with the function
setAttemptsAtGenericReduction and try again.

i12 : setAttemptsAtGenericReduction(R,25)
o12 = 625 attempt(s) will be made to compute the Bass numbers via a
generic reduction

i13 : torAlgClass R

o13 = G(2)

Notice that the maximal number of attempts is $n^2$, where $n$ is the value set with
the function setAttemptsAtGenericReduction.

Notes. Given $Q/I$, our implementation of Algorithm 5 in torAlgData proceeds
as follows.

(1) Check if a value is set for attemptsAtBassNumbers; if not use the default
value 25.

(2) Initialize the invariants of $R$ (the localization of $Q/I$ at the irrelevant maximal
ideal) that are to be returned; see the table on page 5.

(3) Handle the special case where the defining ideal $I$ or $Q/I$ is 0. In all other
cases, compute the invariants $c, e, h, m (= l + 1)$, and $n$.

(4) If possible, classify $R$ based on $c, e, h, m$, and $n$. At this point the implement-
tation deviates slightly from Algorithm 5, as it uses that all rings with $c = 3$
and $h = 2$ are of class $H(0, 0)$; see [Avramov 2012, 3.5].

(5) For rings not classified in steps (3) or (4), one has $c = 3$; see Remark 4.
Compute the Betti numbers $\beta_2, \beta_3,$ and $\beta_4$, and with the formula from Lemma 1,
compute $p$ and $q$. If possible, classify $R$ based on these two invariants.

(6) For rings not classified in steps (3)–(5), compute the Bass numbers $\mu_{e-2}$ and
$\mu_{e-1}$. If $d = e - 3$ is positive, then the Bass numbers are computed via a
reduction modulo a regular sequence of length $d$ as discussed above. Now,
compute $r$ with the formula from Lemma 1 and classify $R$.

(7) The class of $R$ together with the invariants $c, l = m - 1$, and $n$ determine its
Bass and Poincaré series; see [Avramov 2012, 2.1].

If $I$ is homogeneous, then various invariants of $R$ can be determined directly
from the graded ring $Q/I$. If $I$ is not homogeneous, and $R$ hence not graded, then
functions from the package LocalRings are used.
