Strongly stable ideals and Hilbert polynomials

DAVIDE ALBERELLI AND PAOLO LELLA

ABSTRACT: The StronglyStableIdeals.m2 package for Macaulay2 provides a method to compute all saturated strongly stable ideals in a given polynomial ring with a fixed Hilbert polynomial. A description of the main method and auxiliary tools is given.

INTRODUCTION. Strongly stable ideals are a key tool in commutative algebra and algebraic geometry. These ideals have nice combinatorial properties that make them well suited for both theoretical and computational applications. In the case of polynomial rings with coefficients in a field of characteristic zero, the notion of strongly stable ideals coincides with the notion of Borel-fixed ideals. Such ideals are fixed by the action of the Borel subgroup of triangular matrices and play a special role in the theory of Gröbner bases because initial ideals in generic coordinates are of this type [Galligo 1974].

In the context of parameter spaces of algebraic varieties, Galligo’s theorem says that each component and each intersection of components of a Hilbert scheme contains at least one point corresponding to a scheme defined by a Borel-fixed ideal. Hence, these ideals are distributed throughout the Hilbert scheme and can be used to study its local structure. To this end, in recent years several authors [Lella and Roggero 2011; 2016; Cioffi and Roggero 2011; Bertone et al. 2013a; 2017a; 2017b] developed algorithmic methods based on the use of strongly stable ideals to construct flat families corresponding to special loci of the Hilbert scheme. In particular, a new open cover of the Hilbert scheme has been defined using strongly stable ideals and the action of the projective linear group [Bertone et al. 2013b; Brachat et al. 2016]. In this construction, the list of all points corresponding to Borel-fixed ideals in a given Hilbert scheme is needed. The main feature of the package StronglyStableIdeals.m2 is a method to compute this set of points, i.e., the list of all saturated strongly stable ideals in a polynomial ring with a given

The second author is a member of GNSAGA .

Keywords: strongly stable ideal, Borel-fixed ideal, Hilbert polynomial, Gotzmann number, Hilbert scheme.

StronglyStableIdeals.m2 version 1.1
Hilbert polynomial. The method has been theoretically introduced in [Cioffi et al. 2011] and improved in [Lella 2012]. Several other tools are developed and presented in the current paper.

1. STRONGLY STABLE IDEALS. Let us denote by $\mathbb{K}[x]$ the polynomial ring in $n + 1$ variables $\mathbb{K}[x_0, \ldots, x_n]$ with coefficients in a field $\mathbb{K}$. We assume that $x_0 > x_1 > \cdots > x_n$. We use the multi-index notation to describe monomials, i.e., $x^\alpha := x_0^{\alpha_0} \cdots x_n^{\alpha_n}$ for every $\alpha = (\alpha_0, \ldots, \alpha_n) \in \mathbb{Z}^{n+1}_{\geq 0}$, and we denote by $\mathbb{T}_{n,s}$ the set of monomials of $\mathbb{K}[x]$ of degree $s$. For any monomial $x^\alpha$, we denote by $\min x^\alpha$ and $\max x^\alpha$ the indices of the minimal and maximal variable dividing $x^\alpha$.

Following [Green 2010], increasing and decreasing elementary moves are defined as the multiplications

$$e^+_i(x^\alpha) := \frac{x_{i-1}}{x_i} \cdot x^\alpha, \quad i > 0,$$

and

$$e^-_j(x^\alpha) := \frac{x_{j+1}}{x_j} \cdot x^\alpha, \quad j < n.$$

We say that an elementary move $e^{+_/-}_i$ is admissible for a monomial $x^\alpha$ if $\alpha_i > 0$, that is, $e^{+_/-}_i(x^\alpha)$ is a monomial of $\mathbb{K}[x]$.

**Definition 1.1.** An ideal $I \subset \mathbb{K}[x]$ is called strongly stable if

(i) $I$ is a monomial ideal;

(ii) for every $x^\alpha \in I$ and for every admissible increasing move $e^+_i$, the monomial $e^+_i(x^\alpha)$ is contained in $I$.

We recall that a strongly stable ideal is a Borel-fixed ideal. We now summarize some properties holding in general for Borel-fixed ideals and useful in this context.

**Proposition 1.2** [Green 2010, Section 2]. Let $I \subset \mathbb{K}[x]$ be a strongly stable ideal.

(i) The regularity of $I$ is equal to the maximal degree of a generator.

(ii) Let $m$ be the irrelevant ideal of $\mathbb{K}[x]$. Then, $(I : m) = (I : x_n)$, so that the ideal $I$ is saturated if no generator involves the last variable $x_n$.

(iii) The last variable $x_n$ is a regular element for $I$, i.e., the multiplication by $x_n$ induces the short exact sequence

$$0 \rightarrow \frac{\mathbb{K}[x]}{I} (t - 1) \xrightarrow{x_n} \frac{\mathbb{K}[x]}{I} (t) \rightarrow \frac{\mathbb{K}[x]}{(x_n, I)} (t) \rightarrow 0.$$  

2. HILBERT POLYNOMIALS. The Hilbert polynomial $p(t)$ of a homogeneous ideal $I \subset \mathbb{K}[x]$ is the numerical polynomial such that for $s$ sufficiently large

$$\dim_{\mathbb{K}} \left( \frac{\mathbb{K}[x]}{I} \right) = \dim_{\mathbb{K}} \left( \frac{\mathbb{K}[x]}{I} \right) s = \binom{n+s}{n} - \dim_{\mathbb{K}} I_s = p(s).$$
Obviously, not every numerical polynomial is a Hilbert polynomial of some homogeneous ideal. Those being Hilbert polynomials have been completely described by Gotzmann [1978].

**Gotzmann’s decomposition.** A numerical polynomial \( p(t) \in \mathbb{Q}[t] \) is a Hilbert polynomial if, and only if, it can be written as

\[
p(t) = \binom{n+a_1}{a_1} + \binom{n+a_2-1}{a_2} + \cdots + \binom{n+a_r-(r-1)}{a_r}, \quad a_1 \geq \cdots \geq a_r \geq 0.
\]  

(1)

This decomposition is strictly related to Macaulay’s decomposition

\[
p(t) = \sum_{k=0}^{d} \left[ \binom{t+k}{k+1} - \binom{t+k-m_k}{k+1} \right],
\]

where \( d = \deg p(t) \). For all \( n \geq d+1 \) the saturated lexicographic ideal within \( \mathbb{K}[x_0, \ldots, x_n] \) with Hilbert polynomial \( p(t) \) is

\[
(x_0, \ldots, x_{n-d-2}, x_{n-d-1}^{b_{d+1}}, x_{n-d}^{b_d}, x_{n-d-1}^{b_{d-1}+1}, \ldots, x_{n-d}^{b_d}, x_{n-d}^{b_{d-1}} \cdots x_{n-1}^{b_0}),
\]

where

\[
b_d = \# \{ a_j \mid a_j = d \} = m_d \quad \text{and} \quad b_k = \# \{ a_j \mid a_j = k \} = m_k - m_{k+1}, \quad 0 \leq k < d.
\]

The description of the lexicographic ideal in terms of Gotzmann’s decomposition gives an insight to the following theorem.

**Gotzmann’s regularity theorem.** The regularity of a saturated ideal \( I \subset \mathbb{K}[x] \) with Hilbert polynomial \( p(t) \) is at most \( r \), where \( r \) is the number of terms in the decomposition (1) and it is called the **Gotzmann number** of \( p(t) \).

**Example 2.1.** The package **StronglyStableIdeals.m2** provides the method \isHilbertPolynomial\ to determine if a numerical polynomial is a Hilbert polynomial.

Macaulay2, version 1.11

with packages: ConwayPolynomials, Elimination, IntegralClosure, InverseSystems, LLLBases, PrimaryDecomposition, ReesAlgebra, TangentCone

i1 : loadPackage "StronglyStableIdeals";

i2 : QQ[t];

i3 : isHilbertPolynomial (4*t)

o3 = true

i4 : isHilbertPolynomial (5*t-6)

o4 = false

Gotzmann’s and Macaulay’s decompositions of a Hilbert polynomial can be computed using gotzmannDecomposition and macaulayDecomposition. These
methods return the list of terms in the decompositions. The summand \( \binom{s+c}{c} \) is constructed with the command \texttt{projectiveHilbertPolynomial(c,c-e)}.

\[
\begin{align*}
\text{i5 : gotzmannDecomposition (4*t)} & \quad \{P_1, -P + P, -2*P + P, -3*P + P, P, P\} \\
\text{o5 : List} & \\
\text{i6 : macaulayDecomposition (4*t)} & \quad \{-P + P, 7*P - P, -P + P, -10*P + 5*P - P\} \\
\text{o6 : List} & 
\end{align*}
\]

Finally, the saturated lexicographic ideal \( L \) with Hilbert polynomial \( p(t) \) in the polynomial ring \( \mathbb{K}[x] \) can be computed with the method \texttt{lexIdeal} and its regularity is equal to the Gotzmann number of \( p(t) \).

\[
\begin{align*}
\text{i7 : L = lexIdeal (4*t, \text{QQ}[x,y,z,w])} & \quad \text{ideal (x, y, y*z)} \\
\text{o7 : Ideal of \text{QQ}[x, y, z, w]} & \\
\text{i8 : regularity L == gotzmannNumber (4*t)} & \quad \text{true} \\
\text{o8 : true} & 
\end{align*}
\]

3. **THE MAIN ALGORITHM.** In this section, we outline the strategy of the main algorithm. This algorithm was firstly described in [Cioffi et al. 2011] and then optimized in [Lella 2012]. The same problem has been previously discussed in [Reeves 1992] and an alternative algorithm was later presented in [Moore and Nagel 2014].

We need to relate the properties of a strongly stable ideal with its Hilbert polynomial. If \( I \) is a strongly stable ideal, for each \( s \in \mathbb{N} \) the monomial basis of the homogeneous piece \( I_s \) of the ideal is a subset of \( \mathbb{T}_{n,s} \) closed by increasing elementary moves. We call **Borel sets** such subsets of \( \mathbb{T}_{n,s} \) (see Figure 1 for an example). Proposition 1.2(i) implies that the monomial basis of \( I_s \) for a saturated strongly stable ideal \( I \subset \mathbb{K}[x] \) with Hilbert polynomial \( p(t) \) and regularity at most \( s \) is a Borel set with \( q(s) := \binom{n+s}{n} - p(s) \) elements. Thus, we consider the map

\[
\left\{ \begin{array}{l}
\text{saturated strongly stable ideals in } \mathbb{K}[x] \text{ with Hilbert polynomial } p(t) \text{ and regularity } \leq s \\
\end{array} \right\} \leftrightarrow \left\{ \begin{array}{l}
\text{Borel sets of } \mathbb{T}_{n,s} \\
\text{with } q(s) \text{ elements}
\end{array} \right\}. \quad (2)
\]

Moreover, Gotzmann’s regularity theorem suggests considering \( s \) equal to the Gotzmann number of \( p(t) \) to determine all saturated strongly stable ideals with Hilbert polynomial \( p(t) \). Obviously, there are many Borel sets in \( \mathbb{T}_{n,s} \) with \( q(s) \) elements not corresponding to an ideal with Hilbert polynomial \( p(t) \). To identify the image of the previous map, we recall a definition and a proposition by Mall.
Figure 1. The Borel sets defined in \( \mathbb{T}_{2,3} \) and \( \mathbb{T}_{2,4} \) by the ideal 
\((x_0^2, x_0x_1, x_1^4) \subset \mathbb{K}[x_0, x_1, x_2]\).

**Definition 3.1** [Mall 1997, Definition 2.7]. Let \( B \subset \mathbb{T}_{n,s} \) be a Borel set. The set 
\( B^{(i)} := \{ x^\alpha \in B \mid \min x^\alpha = n - i \} \) is called the \( i \)-growth class of \( B \). The sequence 
\( \text{gv}(B) := (|B^{(0)}|, \ldots, |B^{(n)}|) \) is called the growth vector of \( B \).

**Proposition 3.2** [Mall 1997, Proposition 3.2]. Let \( I \subset \mathbb{K}[x] \) be a strongly stable 
ideal generated by the monomials of a Borel set \( B \subset \mathbb{T}_{n,s} \) and let \( p(t) \) be its Hilbert polynomial. Then,

\[
p(t) = \binom{n + t}{n} - \sum_{k=0}^{n} |B^{(k)}| \binom{k + t - s}{k}, \quad \text{for all } t \geq s. \tag{3}
\]

We can use this result to determine the growth vector of a Borel set \( B \subset \mathbb{T}_{n,s} \)
starting from the Hilbert polynomial. The \( i \)-th difference polynomial of \( p(t) \) is

\[
(\Delta^i p)(t) = (\Delta^{i-1} p)(t) - (\Delta^{i-1} p)(t - 1) = \binom{n + t - i}{n - i} - \sum_{k=i}^{n} |B^{(k)}| \binom{k + t - s - i}{k - i}.
\]

Evaluating these identities at \( t = s \), we obtain the linear system

\[
\begin{align*}
\sum_{k=0}^{n} |B^{(k)}| &= \binom{n + s}{n} - p(s), \\
\vdots
\sum_{k=i}^{n} |B^{(k)}| &= \binom{n + s - i}{n - i} - (\Delta^i p)(s), \\
\vdots
|B^{(n)}| &= \binom{s}{0} - (\Delta^n p)(s), \tag{4}
\end{align*}
\]

whose solution is

\[
|B^{(i)}| = \sum_{k=i}^{n} |B^{(k)}| - \sum_{k=i+1}^{n} |B^{(k)}| = \binom{n + s - i - 1}{n - i} - (\Delta^i p)(s) + (\Delta^{i+1} p)(s), \quad i < n,
\]

and \( |B^{(n)}| = 1 \) (recall that \( (\Delta^i p)(t) \equiv 0 \) for \( i > \deg p(t) \) and \( \deg p(t) < n \)). Let us 
call the growth vector of \( p(t) \) in degree \( s \) the solution of the linear system (4) and 
let us denote it by \( \text{gv}_s(p(t)) \).
Proposition 3.3 (cf. [Lella 2012, Theorem 3.3]). Let \( p(t) \) be a Hilbert polynomial. There is a bijective map

\[
\begin{align*}
\text{saturated strongly stable ideals} & \quad \xrightarrow{1:1} \quad \text{Borel sets of } \mathbb{T}_{n,s} \\
\text{in } \mathbb{K}[x] \text{ with Hilbert polynomial } p(t) \text{ and regularity } \leq s & \quad \xrightarrow{1:1} \quad \text{with } q(s) \text{ elements and growth vector } \text{gv}_s(p(t))
\end{align*}
\]

In order to determine the Borel sets of Proposition 3.3, we use a recursive algorithm based on Proposition 1.2(iii). Indeed, if \( I \subset \mathbb{K}[x_0, \ldots, x_n] \) is a strongly stable ideal with Hilbert polynomial \( p(t) \) and \( B \) is the associated Borel set in \( \mathbb{T}_{n,s} \), then the subset \( B' = \{ x^{\alpha} \in B \mid \min x^{\alpha} > n \} \subset B \) is a Borel set in \( \mathbb{T}_{n-1,s} \) corresponding to the strongly stable ideal \( I' = (x_n, I) \cap \mathbb{K}[x_0, \ldots, x_{n-1}] \subset \mathbb{K}[x_0, \ldots, x_{n-1}] \) with Hilbert polynomial \( \Delta p(t) \).

Example 3.4. We want to determine the set of strongly stable ideals in the polynomial ring \( \mathbb{K}[x_0, x_1, x_2] \) with regularity at most 5 defining schemes with Hilbert polynomial \( p(t) = t + 6 \). The Gotzmann number of \( p(t) \) is 6 and its growth vector in degree 5 is \( \text{gv}_5(t + 6) = (5, 4, 1) \). We start considering the set of strongly stable ideals in \( \mathbb{K}[x_0, x_1] \) with Hilbert polynomial \( \Delta p(t) = 1 \) and regularity at most 5 corresponding to Borel sets with growth vector \( \text{gv}_5(\Delta p(t)) = (4, 1) \). There is a unique Borel set

\[
B' = \{ x_0^5, x_0^4 x_1, x_0^3 x_1^2, x_0^2 x_1^3, x_0 x_1^4 \}.
\]

Since \( x_1^5 \) is not contained in \( B' \), a Borel set \( B \subset \mathbb{T}_{2,5} \) with growth vector \( (5, 4, 1) \) does not contain monomials obtained from \( x_1^5 \) by applying decreasing elementary moves, i.e., \( x_1^4 x_2, x_1^3 x_2^2, x_1^2 x_2^3, x_1 x_2^4 \) and \( x_1^5 \). Hence, we need to select five monomials divisible by both \( x_0 \) and \( x_2 \) producing a set closed by increasing elementary moves (see Figure 2).
Our package provides the method `stronglyStableIdeals` to compute the set of strongly stable ideals of a given polynomial ring with fixed Hilbert polynomial and bounded regularity.

```plaintext
i9 : stronglyStableIdeals (4*t, QQ[x,y,z,w])
o9 = {ideal (x, y, y z), ideal (x*z, x*y, x, y z, y),
     ideal (x+y, x, x*z, y), ideal (x+y, x, y)}
o9 : List
i10 : stronglyStableIdeals (4*t, QQ[x,y,z,w], MaxRegularity => 4)
o10 = {ideal (x*y, x, x*z, y), ideal (x*y, x, y)}
o10 : List
```

4. SEGMENT IDEALS. The transitive closure of the order relation

\[ x^\alpha >_B x^\beta \iff x^\beta = e_i (x^\alpha) \]  \hspace{1cm} (6)

induces a partial order on the set of monomials of any degree called the Borel order. Every graded term ordering is a refinement of this partial order. Since a Borel set \( B \) is closed with respect to the Borel order, i.e., \( x^\alpha >_B x^\beta, x^\beta \in B \Rightarrow x^\alpha \in B \), it is natural to ask whether there exists a term ordering \( < \) with the same property. For instance, for the lexicographic ideal, the graded lexicographic order separates, in each degree, monomials contained in the ideal from those outside. In [Cioffi et al. 2011], several notions of segment ideals are introduced.

**Definition 4.1** [Cioffi et al. 2011, Definitions 3.1 and 3.7]. A Borel set \( B \subset T_{n,s} \) is called a segment if there exists a term ordering \( < \) such that \( x^\alpha > x^\beta \), for all \( x^\alpha \in B \) and \( x^\beta \in T_{n,s} \setminus B \).

Let \( I \subset K[x] \) be a saturated strongly stable ideal.

(i) \( I \) is called a *hilb-segment* if the Borel set \( I \cap T_{n,r} \) is a segment, where \( r \) is the Gotzmann number of the Hilbert polynomial of \( I \).

(ii) \( I \) is called a *reg-segment* if the Borel set \( I \cap T_{n,m} \) is a segment, where \( m \) is the regularity of \( I \).

(iii) \( I \) is called a *gen-segment* if there exists a term ordering \( < \) such that \( x^\alpha > x^\beta \) for each minimal generator \( x^\alpha \) of degree \( s \) of \( I \) and for all \( x^\beta \in T_{n,s} \setminus I_s \).

These notions are very important in the construction of flat families based on properties of Gröbner bases and in general for the study of the Hilbert scheme. The `StronglyStableIdeals.m2` package provides three methods for determining whether a strongly stable ideal may be some type of segment (and, in case, gives the term ordering). These methods use tools of the package `gfanInterface.m2` and the term ordering is given as a weight vector.
