Computing Igusa’s local zeta function of univariates in deterministic polynomial-time

Ashish Dwivedi and Nitin Saxena
Computing Igusa’s local zeta function of univariates in deterministic polynomial-time

Ashish Dwivedi and Nitin Saxena

Igusa’s local zeta function $Z_{f,p}(s)$ is the generating function that counts the number of integral roots, $N_k(f)$, of $f(x) \mod p^k$, for all $k$. It is a famous result, in analytic number theory, that $Z_{f,p}$ is a rational function in $\mathbb{Q}(p^s)$. We give an elementary proof of this fact for a univariate polynomial $f$. Our proof is constructive as it gives a closed-form expression for the number of roots $N_k(f)$.

Our proof, when combined with the recent root-counting algorithm of Dwivedi, Mittal and Saxena (Computational Complexity Conference, 2019), yields the first deterministic poly$(|f|, \log p)$-time algorithm to compute $Z_{f,p}(s)$. Previously, an algorithm was known only in the case when $f$ completely splits over $\mathbb{Q}_p$; it required the rational roots to use the concept of generating function of a tree (Zúñiga-Galindo, J. Int. Seq., 2003).

1. Introduction

Over the years, the study of zeta functions has played a foundational role in the development of mathematics. They have applications in diverse science disciplines; in particular, machine learning [72], cryptography [2; 3], quantum cryptography [45], statistics [72; 47], theoretical physics [31; 53], string theory [51], quantum field theory [27; 31] and biology [57; 77]. Basically, a zeta function counts some mathematical objects. Often zeta functions show special analytic, or algebraic properties, the study of which can reveal striking information about the encoded object.

A classic example is the famous Riemann zeta function [54] (also known as the Euler–Riemann zeta function) which encodes the density and distribution of prime numbers [16; 64]. Later many local (i.e., associated to a specific prime $p$) zeta functions were studied; e.g., the Hasse–Weil zeta function [73; 74], which encodes the count of zeros of a system of polynomial equations over finite fields (of a specific characteristic $p$). The study of this function led to the development of modern algebraic geometry (see [19; 30]).

In this paper we are interested in a different local zeta function known as Igusa’s local zeta function. It encodes the count of roots modulo prime powers of a given polynomial defined over a local field.

MSC2010: primary 11S40, 68Q01, 68W30; secondary 11Y16, 14G50.
Keywords: Igusa, local, zeta function, discriminant, valuation, deterministic, root, counting, modulo, prime power.
Formally, Igusa’s local zeta function $Z_{f,p}(s)$, attached to a polynomial over $p$-adic integers

$$f(x) \in \mathbb{Z}_p[x_1, \ldots, x_n]$$

is defined as

$$Z_{f,p}(s) := \int_{\mathbb{Z}_p^n} |f(x)|_p^s |dx|,$$

where $s \in \mathbb{C}$ with $\text{Re}(s) > 0$, $|\cdot|_p$ denotes the absolute value over $p$-adic numbers $\mathbb{Q}_p$, and $|dx|$ denotes the Haar measure on $\mathbb{Q}_p^n$ normalized so that $\mathbb{Z}_p^n$ has measure 1.

Weil [75; 76] defined these zeta functions inspired by those of Riemann. Later they were studied extensively by Igusa [34; 35; 36]. Using the method of resolution of singularities, Igusa proved that $Z_{f,p}(s)$ converges to a rational function. Later the convergence was proved by Denef [20] via a different method (namely, $p$-adic cell decomposition). The Igusa zeta function is closely related to Poincaré series $P(t)$, attached to $f$ and $p$, defined as

$$P(t) := \sum_{i=0}^{\infty} N_i(f) \cdot (p^{-n}t)^i,$$

where $t \in \mathbb{C}$ with $|t| < 1$, and $N_i(f)$ is the count on roots of $f$ mod $p^i$ (also $N_0(f) := 1$). In fact, it has been shown in [33] that

$$P(t) = \frac{1 - t \cdot Z_{f,p}(s)}{1 - t}$$

with $t =: p^{-s}$. So rationality of $Z_{f,p}(s)$ implies rationality of $P(t)$ and vice versa; thus proving a conjecture of [52] that $P(t)$ is a rational function. This relation makes the local zeta function interesting in arithmetic geometry (see [33; 21; 50; 44] for more on the Igusa zeta function).

Many researchers have tried to calculate the expression for the Igusa zeta function for various polynomial families [17; 56; 66; 1; 22; 48; 65; 32; 58; 79; 81] and this has led to the development of various methodologies; for example, the stationary phase formula (SPF), the Newton polygon method, resolution of singularities, etc. These methods have been fruitful in various other situations [23; 82; 83; 59; 39; 40; 84; 68; 61; 85]. However, not much has been said about their algorithmic aspect except in the case of resolution of singularities [6; 9; 8; 67]. These algorithms are impractical [7]. Indeed, the computation of the Igusa zeta function for a general multivariate polynomial seems to be an intractable problem since root-counting of a multivariate polynomial over a finite field is known to be #P-hard [28; 26].

In this paper, we focus on the computation of the Igusa zeta function when the associated polynomial is univariate. The Igusa zeta function for a univariate polynomial $f$ is connected to root-counting of $f$ modulo prime powers $p^k$, which is itself an interesting problem. It has applications in factoring [13; 14; 10], coding theory [4; 60], elliptic curve cryptography [43], arithmetic algebraic geometry [80; 22; 21], and the study of root sets [62; 15; 5; 18; 49]. After a long series of work [70; 71; 38; 60; 4; 63; 12; 42; 25], this problem was recently resolved in [24].
In the case of univariate polynomials one naturally expects an elementary proof of convergence, as well as an efficient algorithm to compute the Igusa zeta function. Our main result is:

We give the first deterministic polynomial time algorithm to compute the rational function form of the Igusa zeta function associated to a given univariate polynomial $f \in \mathbb{Z}[x]$ and prime $p$.

To the best of our knowledge, this result was previously achieved only for the restricted class of univariate polynomials using methods that were sophisticated and nonexplicit. For example, Zúñiga-Galindo [80] achieved this for univariate polynomials which completely split over $\mathbb{Q}$ (with the factorization given in the input), using the stationary phase formula (see Section 1.2). The methods to compute the Igusa zeta function for a multivariate, e.g., Denef [20], continue to be impractical in the case of univariate polynomials. On the other hand, our approach is elementary, uses explicit methods, and completely solves the problem.

1.1. Our results. We will compute the Igusa zeta function $Z_{f,p}(s)$ by finding the related Poincaré series $P(t) =: A(t)/B(t)$.

**Theorem 1.** We are given a univariate integral polynomial $f(x) \in \mathbb{Z}[x]$ of degree $d$, with coefficients of magnitude bounded by $C \in \mathbb{N}$, and a prime $p$. Then, we compute the Poincaré series $P(t) = A(t)/B(t)$, associated with $f$ and $p$, in deterministic poly($d, \log C + \log p$)-time.

The degree of the integral polynomial $A(t)$ is $\tilde{O}(d^2 \log C)$ and that of $B(t)$ is $O(d)$.

**Remarks.**

(1) Our method gives an elementary proof of rationality of $Z_{f,p}(s)$ as a function of $t = p^{-s}$.

(2) Previously, Zúñiga-Galindo [80] gave a deterministic polynomial time algorithm to compute $Z_{f,p}(s)$, if $f$ completely splits over $\mathbb{Q}$ and the roots are provided. Our Theorem 1 works for any input $f \in \mathbb{Z}[x]$ (see Section 1.2 for further discussion).

(3) Cheng et al. [12] could compute $Z_{f,p}(s)$ in deterministic polynomial time, in the special case where the degree of $A(t)$, $B(t)$ is constant.

(4) Dwivedi et al. [24], using [80], remarked that $Z_{f,p}(s)$ could be computed in deterministic polynomial time, in the special case when $f$ completely splits over $\mathbb{Q}_p$ without the roots being provided in the input. The detailed proof of this claim was not given and the convergence relied on the old method of [80].

We achieve the rational form of $Z_{f,p}(s)$ by getting an explicit formula for the number of zeros $N_k(f)$, of $f \mod p^k$, which sheds new light on the properties of the function $N_k(\cdot)$. Eventually, it gives an elementary proof of the rationality of the Poincaré series $\sum_{i=0}^{\infty} N_i(f) \cdot (p^{-1}t)^i$.

**Corollary 2.** Let $k$ be large enough, namely, $k \geq k_0 := O(d^2(\log C + \log d))$. Then, we give a closed form expression for $N_k(f)$ (in Theorem 21).

Interestingly, if $f$ has nonzero discriminant, then $N_k(f)$ is constant (independent of $k$) for all $k \geq k_0$.

1.2. Further remarks and comparison. To the best of our knowledge, there have been very few results on the complexity of computing Igusa’s zeta function for univariate polynomials [80; 12]. Other very
specialized algorithms are for bivariate polynomials (e.g., hyperelliptic curves) [11], and for the polynomial \(x^d - a\) [65]. In a recent related work [78, Appendix A], a different proof of rationality of Igusa’s zeta function for univariate polynomials based on tree based algorithm of [42] is given.

An old proof technique called the \textit{stationary phase formula} is the standard method used in the literature to compute Igusa’s zeta function for various families of polynomials. Our work, on the other hand, uses elementary techniques and a tree-based root-counting algorithm [24] to compute some fixed parameters (independent of \(k\)) involved in our formula of \(N_k(f)\), for all \(k \geq k_0\).

It is to be noted that just efficiently computing \(N_k(f)\), for “several” \(k\), is not enough to compute the rational form of \(Z_{f,p}(s)\); neither does it imply the rationality of \(Z_{f,p}(s)\) directly.

Our algorithm is \textit{deterministic} and works for general \(f \in \mathbb{Z}_p[x]\) (provided \(f\) has computable representation). For earlier methods to work for \(f \in \mathbb{Z}_p[x]\) they may need factoring over \(p\)-adics \(\mathbb{Z}_p\) or \(\mathbb{Q}_p\) (for example [80]), but deterministic algorithms there are unknown. See [13; 14; 10] for randomized factoring algorithms.

1.3. Proof idea. We will compute the rational form of Igusa’s zeta function via computing the rational form of corresponding Poincaré series

\[
P(t) := \sum_{i=0}^{\infty} N_i(f) \cdot (p^{-1} t)^i.
\]

In addition, our method proves that the Poincaré series is a rational function of \(t\), in the case of univariate polynomial \(f(x)\), via first principles; instead of using advanced tools like the stationary phase method or Newton polygon method or resolution of singularity.

To compute the rational form of Poincaré series, the idea is to compute the coefficient sequence

\[
\{N_0(f), \ldots, N_k(f), \ldots\}
\]

in a closed form. That is to say, we wish to get an explicit formula for \(N_k(f)\), the number of roots of \(f \mod p^k\), only in terms of \(k\); with the hope that this will help in getting a rational function for the Poincaré series \(P(t)\).

Indeed in Theorem 21, we show that such a formula exists for each \(N_k(f)\) for sufficiently large \(k\). We achieve this by establishing a connection among roots of \(f \mod p^k\) and \(\mathbb{Z}_p\)-roots of \(f \in \mathbb{Z}_p[x]\). Let \(f\) have \(n\) distinct \(\mathbb{Z}_p\)-roots \(\alpha_1, \ldots, \alpha_n\). An important concept we define is that of “neighborhood” of an \(\alpha_i \mod p^k\) (Definition 18); these are basically roots of \(f \mod p^k\) “associated” to \(\alpha_i\). In Lemma 15, we show that each root \(\overline{\alpha}\) of \(f \mod p^k\) is associated to a unique \(\mathbb{Z}_p\)-root \(\alpha_i\) of \(f\): \(\overline{\alpha}\) closely approximates \(\alpha_i\) but is quite far from other \(\alpha_j\)’s, for all \(j \in [n], j \neq i\). So, the root-set of \(f \mod p^k\) can be partitioned into \(n\) subsets \(S_{k,i}, i \in [n]\), where neighborhood \(S_{k,i}\) is the set of those roots of \(f \mod p^k\) which are associated to \(\mathbb{Z}_p\)-root \(\alpha_i\).

Let the multiplicity of root \(\alpha_i\) be \(e_i\); then \(f(x) = (x - \alpha_i)^{e_i} f_i(x)\) over \(\mathbb{Z}_p\), where \(f_i(\alpha_i) \neq 0\). We call \(f_i\) the \(\alpha_i\)-free part of \(f\). Then, for \(\overline{\alpha}\) to be a root of \(f \mod p^k\) we must have

\[
f(\overline{\alpha}) \equiv (\overline{\alpha} - \alpha_i)^{e_i} \cdot f_i(\overline{\alpha}) \equiv 0 \mod p^k.
\]
Throughout the paper we call such sets `representatives`.

Lemma 16 says that \( f_i \) possesses equal valuation \( v_i \), for all roots of \( f \mod p^k \) associated to \( \alpha_i \), i.e., ones in \( S_{k,i} \). That is, the maximum power of \( p \) dividing \( f_i(\overline{\alpha}) \) is the same as that for \( f_i(\overline{\beta}) \), as long as \( \overline{\alpha}, \overline{\beta} \in S_{k,i} \). Note that \( v_p((\overline{\alpha} - \alpha_i)^{e_i} \cdot f_i(\overline{\alpha})) \geq k \) if and only if \( v_p((\overline{\alpha} - \alpha_i)) \geq (k - v_i)/e_i \).

Eventually, these two lemmas together give us the size of the neighborhood, \( |S_{k,i}| = p^{k - [(k - v_i)/e_i]} \). Moreover, the neighborhoods disjointly cover all the roots of \( f \mod p^k \). Hence, \( N_k(f) = \sum_{i=1}^n |S_{k,i}| \).

This is a formula for \( N_k(f) \), when \( k \) is large. But still the two parameters \( v_i \) and \( e_i \) are unknown as, unlike in [80], we are not provided the factorization of \( f \) over \( \mathbb{Z}_p \) (nor could we find it in deterministic polynomial time).

To compute \( v_i, e_i \), we use the help of the root-counting algorithm of [24], which gives us the value of \( N_k(f) \), and the underlying root-set structure that it developed. We show that each representative root \( \overline{\alpha}_i \) of \( f \mod p^k \) is indeed the neighborhood \( S_{k,i} \) (Theorem 19), shedding new light on the root-set mod prime powers.

Now we can get two equations, for the two unknowns \( v_i, e_i \), by calling the algorithm of [24] twice: first for \( k = k_i \) and second for \( k = k_i + e_i \), where \( k_i \) is such that \( (k_i - v_i)/e_i \) is an integer (e.g., we can try all \( k_i \) in the range \( \{k_0, \ldots, k_0 + \deg(f)\} \)). So, we can efficiently compute \( v_i, e_i \) for a particular representative root \( \overline{\alpha}_i \), \( i \in [n] \). So, this calculation also reveals some new parameters of representative roots which were not mentioned in earlier related works [4; 24].

## 2. Preliminaries

### 2.1. Root-set of a univariate polynomial mod prime powers

We recall a structural property (and related objects) of the root-set of univariate polynomials in the ring \( \mathbb{Z}/(p^k) \) [24; 25].

**Proposition 3.** The root-set of an integral univariate polynomial \( f \), over the ring of integers modulo prime powers, is the disjoint union of at most \( \deg(f) \) many efficiently representable subsets.

We call these efficiently representable subsets `representative roots`, as defined and named in [25, Section 2]. This property of root-sets in \( \mathbb{Z}/(p^k) \) is indeed a generalization of the property of root-sets over a field: there are at most \( \deg(f) \) many roots of \( f(x) \) in a field.

To present representative roots formally, we first reiterate some notation from [25, Section 2].

**Representatives.** An abbreviation `*` will be used to denote all of the underlying ring \( R \). So for the ring \( R = \mathbb{Z}/(p^k) \), `*` denotes all the \( p^k \) distinct elements. Perceiving any element of \( R \) in base-\( p \) representation, like \( x_0 + p x_1 + \cdots + p^{k-1} x_{k-1} \) where \( x_i \in \{0, \ldots, p-1\} \) for all \( i \in \{0, \ldots, k-1\} \), the set

\[
a := a_0 + p a_1 + \cdots + p^{l-1} a_{l-1} + p^l * \tag{1}
\]

“represents” the set of all the elements of \( R \) which are congruent to \( a_0 + p a_1 + \cdots + p^{l-1} a_{l-1} \mod p^l \). Throughout the paper we call such sets `representatives` and we denote them using bold small letters, like \( a, b \) etc.

Let us denote the `length` of a representative \( a \) by \(|a|\), so if \( a := a_0 + p a_1 + \cdots + p^{l-1} a_{l-1} + p^l * \) then its length is \(|a| = l \). Now we formally define representative roots of a univariate polynomial in \( \mathbb{Z}/(p^k) \).
**Definition 4** (representative roots). A set
\[ a = a_0 + pa_1 + \cdots + p^{l-1}a_{l-1} + p^l * \]
is called a representative root of \( f(x) \) modulo \( p^k \) if each \( \alpha \in a \) is a root of \( f(x) \) mod \( p^k \), but, not all \( \beta \in b := a_0 + pa_1 + \cdots + p^{l-2}a_{l-2} + p^{l-1} * \) are roots of \( f(x) \) mod \( p^k \).

It was first observed in [4] that there are at most \( \deg(f) \)-many representative roots and they gave an efficient randomized algorithm to compute all these representative roots (for a simple exposition of the algorithm, see [25, Section B]).

We need a deterministic algorithm for our purpose (in Section 3.4) to count, if not find, the representative roots (as well as count the roots in each representative root). So we use the deterministic polynomial time algorithm of [24] which returns all these representative roots implicitly in the form of a data-structure they call maximal split ideals (MSI). The two explicit parameters, length and degree of an MSI immediately gives the count on the number of representative roots (as well as roots) encoded by them, which suffices for our purpose. A similar idea to use triangular ideals for encoding roots first appeared in [12], to count roots deterministically, but for “small” \( k \).

We now define MSI from [24, Section 2].

**Definition 5** ([24, Section 2], maximal split ideals). A triangular ideal
\[ I = \langle h_0(x_0), \ldots, h_l(x_0, \ldots, x_i) \rangle, \]
where \( 0 \leq l \leq k - 1 \) and each \( h_l(x_0, \ldots, x_i) \in \mathbb{F}_p[x_0, \ldots, x_i] \), is called a maximal split ideal of \( f(x) \) mod \( p^k \) if

1. the number of common zeros of \( h_0, \ldots, h_l \) in \( \mathbb{F}_p^{l+1} \) is \( \prod_{i=0}^{l} \deg_{x_i}(h_i) \), where \( \deg_{x_i} \) denotes the individual degree wrt \( x_i \), and

2. for every common zero \( (a_0, \ldots, a_i) \in \mathbb{F}_p^{l+1} \) of \( h_0, \ldots, h_l \), \( f(x) \) vanishes identically modulo \( p^k \) with the substitution \( x \to a_0 + pa_1 + \cdots + p^l a_l + p^l x \) but not with \( x \to a_0 + \cdots + p^l a_l + p^l x \).

For an MSI \( I \) given by its generators \( h_0(x_0), \ldots, h_l(x_0, \ldots, x_i) \) we define its length to be \( l + 1 \) and degree, denoted as \( \deg(I) \), to be the number of common zeros of its generators, which is \( \prod_{i=0}^{l} \deg_{x_i}(h_i) \) by definition.

Essentially, \( I \) is encoding some representative roots of \( f \) mod \( p^k \) in the form of common roots of its generators. Indeed, condition (2) of the definition is similar to that of representative roots. If \( (a_0, \ldots, a_l) \) is a common zero of the generators then by condition (2), \( a_0 + pa_1 + \cdots + p^l a_l + p^l x \) follows all the conditions to be a representative root. Then, it is apparent that:

**Lemma 6** ([24, Lemmas 6 and 8]). The length of an MSI \( I \) is the length of each representative root encoded by it and the degree of \( I \) is the count on these representative roots. Thus, we get the count on the roots of \( f \) mod \( p^k \) encoded by \( I \) as \( \prod_{i=0}^{l} \deg_{x_i}(h_i) \times p^{k-l-1} \).

We state the result of [24] which returns all the representative roots, in MSI form, in deterministic polynomial time.
Theorem 7 (compute $N_k(f)$ [24]). In deterministic poly($|f|, k \log p$)-time one gets the maximal split ideals which collectively contain exactly the representative roots of a univariate polynomial $f(x) \in \mathbb{Z}[x]$ modulo prime power $p^k$.

Using Lemma 6 we can count them, and all roots of $f \mod p^k$, in deterministic polynomial time.

2.2. Some definitions and notation related to $f$. We are given an integral univariate polynomial $f(x)$ in $\mathbb{Z}[x]$ of degree $d$ with coefficients of magnitude at most $C \in \mathbb{N}$, and a prime $p$. Then, $f$ can also be thought of as an element of $\mathbb{Z}_p[x]$ (as $\mathbb{Z} \subseteq \mathbb{Z}_p$), where $\mathbb{Z}_p$ is the ring of integers of $p$-adic rational numbers $\mathbb{Q}_p$. In such a field $\mathbb{Q}_p$ (called a nonarchimedean local field) there exists a valuation function $v_p : \mathbb{Q}_p \to \mathbb{Z} \cup \{\infty\}$. Formally, the valuation $v_p(a)$ of $a \in \mathbb{Z}_p$ ($\mathbb{Z}_p$ is a UFD) is defined to be the highest power of $p$ dividing $a$, when $a \neq 0$, and $\infty$ when $a = 0$. This definition extends to the rationals $\mathbb{Q}_p$ naturally as $v_p(a/b) := v_p(a) - v_p(b)$, where $b \neq 0$ and $a, b \in \mathbb{Z}_p$ (see [41]).

Now we define the factors of $f$ in $\mathbb{Z}_p[x]$ as follows (note: we do not require $f$ to be monic).

Definition 8. Let the $p$-adic integral factorization of $f$ into coprime irreducible factors be

$$f(x) = \prod_{i \in [n]} (x - \alpha_i)^{e_i} \cdot \prod_{j=1}^{m} g_j(x)^{f_j},$$

where each $\alpha_i$ is a $\mathbb{Z}_p$-root of $f$ with multiplicity $e_i$. Each $g_j(x) \in \mathbb{Z}_p[x]$ has multiplicity $t_j$; it is irreducible over $\mathbb{Z}_p$ and has no $\mathbb{Z}_p$-root.

For example, over $\mathbb{Z}_2$, $f = 2x^2 + 3x + 1 = (x + 1) \cdot (2x + 1)$ has $n = m = 1$.

Definition 9. For each $i \in [n]$, we define $f_i(x) \in \mathbb{Z}_p[x]$, called the $\alpha_i$-free part of $f$, as $f_i(x) := f(x)/(x - \alpha_i)^{e_i}$. We denote the valuation $v_p(f_i(\alpha_i))$ as $v_i$, for all $i \in [n]$.

The **radical** of a univariate polynomial $h(x)$ over a field $\mathbb{F}$ is defined to be the univariate polynomial, denoted by $\text{rad}(h)$, which is the product of coprime irreducible factors of $h$. This gives rise to the following definition.

Definition 10. Define $\text{rad}(f) := \left(\prod_{i=1}^{n} (x - \alpha_i)\right) \cdot \left(\prod_{j=1}^{m} g_j(x)\right)$. Analogously, the radical of $f_i$, for each $i \in [n]$, is defined as $\text{rad}(f_i) := \text{rad}(f)/(x - \alpha_i)$.

The **discriminant** of a polynomial $h(x) \in \mathbb{F}[x]$ is defined as $D(h) := h_m^{2m-1} \cdot \prod_{1 \leq i < j \leq m} (r_i - r_j)^2$, where $\mathbb{F}$ is a field, the $r_i$’s are the roots of $h(x)$ over the algebraic closure $\overline{\mathbb{F}}$, the degree of $h$ is $m$, and $h_m$ is its leading coefficient.

The discriminant $D(h)$ is an element of $\mathbb{F}$. It is clear by the definition that all the roots of $h$ are distinct if and only if $D(h) \neq 0$; i.e., the discriminant of the radical is nonzero.

Definition 11. We denote by $\Delta$ the valuation with respect to $p$ of the discriminant of the radical of $f$, i.e., $\Delta := v_p(D(\text{rad}(f)))$.

We see that $\Delta$ must be finite, since roots of $\text{rad}(f)$ are distinct. The following fact is easily established by the definition of discriminant and the fact that $\alpha_1, \ldots, \alpha_n$ are also roots of $\text{rad}(f)$.
Fact 12. For $i \neq j \in [n]$, we have $v_p(\alpha_i - \alpha_j) \leq \Delta/2 < \infty$.

For our algorithm, $\Delta$ will be crucial in informing us about the behavior of the roots of $f \mod p^k$.

Properties of discriminants.

1. Over $\mathbb{Z}_p$, if $u(x) \mid w(x)$ then $D(u) \mid D(w)$ and $v_p(D(u)) \leq v_p(D(w))$.
2. The discriminant of a linear polynomial is defined to be 1.
3. If $w(x) = (x - a) \cdot u(x)$ then by the definition of discriminant, it is clear that $D(w) = D(u) \cdot u(a)^2$.
4. The discriminant $D(h)$ of a degree-$l$ univariate polynomial $h(x) := h_0 x^l + \cdots + h_1 x + h_0$, over $\mathbb{Z}_p$, is also a multivariate polynomial over $\mathbb{Z}_p$ in the coefficients $h_0, \ldots, h_l$ (see [46, Chapter 1]). Moreover, it is computable in time polynomial in the size of a given $h$ (e.g., using the determinant of a Sylvester matrix [69, Chapter 11, Section 2]).

3. Proof of main results

3.1. Interplay of $\mathbb{Z}_p$-roots and $(\mathbb{Z}/(p^k))$-roots. In this section we will establish a connection between $(\mathbb{Z}/(p^k))$-roots and $\mathbb{Z}_p$-roots of the given $f$, when $k$ is sufficiently large, i.e, $k > d \Delta$ (see Section 2.2 for the related notation).

Recall that $\alpha_1, \ldots, \alpha_n$ are the distinct $\mathbb{Z}_p$-roots of $f$ (Definition 8). The following claim establishes a notion of “closeness” of any $\overline{\alpha} \in \mathbb{Z}_p$ to an $\alpha_j$. Later we will apply this to a representative root $\overline{\alpha}$.

Claim 13 (close to a root). For some $j \in [n]$, $\overline{\alpha} \in \mathbb{Z}_p$, if $v_p(\overline{\alpha} - \alpha_j) > \Delta/2$, then $v_p(\overline{\alpha} - \alpha_i) = v_p(\alpha_j - \alpha_i) \leq \Delta/2$, for all $i \neq j, i \in [n]$.

Proof. The valuation $v_p(\overline{\alpha} - \alpha_j)$ is equal to $v_p(\overline{\alpha} - \alpha_j + \alpha_j - \alpha_i)$. Since $v_p(\overline{\alpha} - \alpha_j) > \Delta/2$ and $v_p(\alpha_j - \alpha_i) \leq \Delta/2$ (by Fact 12), we deduce $v_p(\overline{\alpha} - \alpha_j) = \min\{v_p(\overline{\alpha} - \alpha_j), v_p(\alpha_j - \alpha_i)\} = v_p(\alpha_j - \alpha_i) \leq \Delta/2$. \qed

The following lemma says that an irreducible cannot take values with ever-increasing valuation.

Lemma 14 (valuation of an irreducible). Let $h(x) \in \mathbb{Z}_p[x]$ be a polynomial with no $\mathbb{Z}_p$-root, and discriminant $D(h) \neq 0$. Then, for any $\overline{\alpha} \in \mathbb{Z}_p$, $v_p(h(\overline{\alpha})) \leq v_p(D(h))$.

Proof. We give the proof by contradiction, i.e, we show that if $v_p(h(\overline{\alpha})) > v_p(D(h))$, then $h(x)$ has a root in $\mathbb{Z}_p$.

Define $v_p(D(h)) := d(h)$. Let $\overline{\alpha} \in \mathbb{Z}_p$ such that $h(\overline{\alpha}) \equiv 0 \mod p^\delta$, for $\delta > d(h)$. Then we write $h(x) = (x - \overline{\alpha}) \cdot h_1(x) + p^\delta \cdot h_2(x)$. The two things to note here are:

1. $D(h) \equiv D(h \mod p^\delta) \mod p^\delta$ by discriminants’ property (4) in Section 2.2. Also, $D(h) \neq 0$ is given.

2. Let $h'(x)$ be the first derivative of $h(x)$ and let $i := v_p(h'(\overline{\alpha}))$. Then, we claim that $\delta > d(h) \geq 2i$.

Consider $h'(x) = h_1(x) + (x - \overline{\alpha})h'_1(x) + p^\delta h'_2(x)$. So, $h'(\overline{\alpha}) \equiv h_1(\overline{\alpha}) \mod p^\delta$. By property (3) (Section 2.2) of discriminants, $D(h) \equiv D((x - \overline{\alpha}) \cdot h_1(x)) \equiv D(h_1) \cdot h_1(\overline{\alpha})^2 \equiv D(h_1) \cdot h'(\overline{\alpha})^2 \mod p^\delta$. Then, since $D(h) \neq 0 \mod p^\delta$, we deduce $2i \leq d(h) < \delta$. 
Now, we show that the root $\overline{\alpha}$ of $h \mod p^\delta$ lifts to roots of $h \mod p^{\delta+j}$, for all $j \in \mathbb{Z}^+$. This is due to Hensel’s lemma (see [69, Chapter 15]); for completeness we give the proof.

By Taylor expansion, we have $h(\overline{\alpha} + p^{\delta-i} x) = h(\overline{\alpha}) + h'(\overline{\alpha}) \cdot p^{\delta-i} x + h''(\overline{\alpha}) \cdot p^{2(\delta-i)} x^2/2! + \cdots$.

Note that there exists a unique solution $x_0 \equiv (-h(\overline{\alpha})/h'(\overline{\alpha}) p^{\delta-i}) \mod p$: $h(\overline{\alpha} + p^{\delta-i} x_0) \equiv 0 \mod p^{\delta+1}$.

This follows from the Taylor expansion and since $2(\delta - i) > \delta$.

So, $\overline{\alpha} - p^{\delta-i}(h(\overline{\alpha})/h'(\overline{\alpha}) p^{\delta-i}) \mod p^{\delta+1}$ is a lift, of $\overline{\alpha}$ mod $p^\delta$. By similar reasoning, it can be lifted further to arbitrarily high powers $p^{\delta+j}$. This proves $h(x)$ has a $\mathbb{Z}_p$-root, which is a contradiction. \qed

The following lemma is perhaps the most important one. It associates every root $\overline{\alpha}$ of $f(x)$ mod $p^k$ to a unique $\mathbb{Z}_p$-root of $f$. Recall the notation from Section 2.2.

**Lemma 15** (unique association). Let $k > d(\Delta + 1)$ and $\overline{\alpha} \in \mathbb{Z}_p$ be a root of $f(x)$ mod $p^k$. There exists a unique $\alpha_i$ such that $v_p(\overline{\alpha} - \alpha_i) > \Delta + 1$ and thus, $v_p(\overline{\alpha} - \alpha_i) > v_p(\alpha_i - \alpha_j)$, for all $j \neq i, j \in [n]$.

*Proof.* Let us first prove that there exists some $i \in [n]$, given $\overline{\alpha}$, such that $v_p(\overline{\alpha} - \alpha_i) > \Delta + 1$. For the sake of contradiction, assume that $v_p(\overline{\alpha} - \alpha_i) \leq \Delta + 1$ for all $i \in [n]$. Then, by Definition 8, $v_p(f(\overline{\alpha})) = \sum_{i=1}^n e_i \cdot v_p(\overline{\alpha} - \alpha_i) + \sum_{j=1}^m f_j \cdot v_p(g_j(\overline{\alpha})) \leq (\Delta + 1) \cdot \sum_{i=1}^n e_i + \sum_{j=1}^m f_j \cdot v_p(g_j(\overline{\alpha}))$.

Since $g_j$ has no $\mathbb{Z}_p$-root, for all $j \in [m]$, by Lemma 14, $v_p(g_j(\overline{\alpha})) \leq v_p(D(g_j))$. By the properties given in Section 2.2 we get $v_p(D(g_j)) \leq v_p(D(\text{rad}(f))) = \Delta$, proving that $v_p(g_j(\overline{\alpha})) \leq \Delta$.

Going back, $v_p(f(\overline{\alpha})) \leq (\Delta + 1) \cdot (-\sum_{i=1}^n e_i + \sum_{j=1}^m f_j) \leq (\Delta + 1) < k$. It implies that $f(\overline{\alpha}) \not\equiv 0 \mod p^k$, which contradicts the hypothesis that $\overline{\alpha}$ is a root of $f$ mod $p^k$.

Thus, there exists $i \in [n]$ such that $v_p(\overline{\alpha} - \alpha_i) > \Delta + 1$. The uniqueness of $i$ follows from Claim 13. \qed

Having seen that every root $\overline{\alpha}$ of $f$ mod $p^k$ is associated (or close) to a unique $\mathbb{Z}_p$-root $\alpha_i$, the following lemma tells us that the valuation of the $\alpha_i$-free part of $f$ (resp. factors of $f$ with no $\mathbb{Z}_p$-root) is the same on any $\overline{\alpha}$ close to $\alpha_i$. This unique valuation is important in getting an expression for $N_k(f)$.

**Lemma 16** (unique valuation). Fix $i \in [n]$. Fix $\overline{\alpha} \in \mathbb{Z}_p$ such that $v_p(\overline{\alpha} - \alpha_i) > \Delta$. Recall $g_j(x), f_i$ from Section 2.2. Then,

1. $v_p(g_j(\overline{\alpha})) = v_p(g_j(\alpha_i))$, for all $j \in [m]$,
2. $v_p(f_i(\overline{\alpha})) = v_p(f_i(\alpha_i))$.

In other words, the valuation with respect to $p$ of $f_i = f(x)/(x-\alpha_i)^{e_i}$, on $x \mapsto \overline{\alpha}$, is fixed uniquely to $v_i := v_p(f_i(\alpha_i))$, for any “close” approximation $\overline{\alpha} \in \mathbb{Z}_p$ of $\alpha_i$.

*Proof.* Since $g_j \mid \text{rad}(f_i)$ and $\text{rad}(f_i) \mid \text{rad}(f)$, we have by the properties of discriminants (Section 2.2) that $v_p(g_j(\alpha_i)) \leq v_p(\text{rad}(f_i)(\alpha_i)) \leq \Delta$, for all $j \in [m]$.

Since $v_p(\overline{\alpha} - \alpha_i) > \Delta$, we deduce $v_p(g_j(\overline{\alpha}) - g_j(\alpha_i)) > \Delta$. Furthermore, $v_p(g_j(\alpha_i)) \leq \Delta$ implies $v_p(g_j(\overline{\alpha})) = v_p(g_j(\alpha_i))$. This proves the first part.

By Claim 13, $v_p(\overline{\alpha} - \alpha_u) = v_p(\alpha_i - \alpha_u)$, for all $u \neq i, u \in [n]$. Also, by the first part, $v_p(g_u(\overline{\alpha})) = v_p(g_u(\alpha_i))$, for all $u \in [m]$. Consequently, $v_p(f_i(\overline{\alpha})) = \sum_{u=1, u \neq i}^n e_u \cdot v_p(\alpha_i - \alpha_u) + \sum_{u=1}^m t_u \cdot v_p(g_u(\alpha_i)) = v_p(f_i(\alpha_i))$. This proves the second part. \qed
3.2. Representative roots versus neighborhoods. We now connect the \( \mathbb{Z}_p \)-roots of \( f \) to the representative roots (defined in Section 2.1) of \( f \mod p^k \). Later we characterize each representative root as a “neighborhood” in Theorem 19.

**Lemma 17** (perturb a root). Let \( k > d(\Delta+1) \) and let \( \bar{\alpha} \) be a root of \( f(x) \mod p^k \) with \( l := v_p(\alpha_i - \bar{\alpha}) > \Delta + 1 \), for some \( i \in [n] \) (as in Lemma 15). Then, every \( \bar{\beta} \in \bar{\alpha} + p^l \ast \) is also a root of \( f(x) \mod p^k \).

**Proof.** Since \( f(\bar{\alpha}) \equiv 0 \mod p^k \), we have \( v_p(f(\bar{\alpha})) \geq k \). Using Lemma 16 we have \( v_p(f_i(\bar{\alpha})) = v_p(f(\bar{\alpha})) = v_p(\alpha_i - \bar{\alpha}) \cdot e_i + v_p(f_i(\bar{\alpha})) = v_p(\alpha_i - \bar{\alpha}) \cdot e_i + v_i \geq k \).

Similarly, \( v_p(f(\bar{\beta})) = v_p(\alpha_i - \bar{\beta}) \cdot e_i + v_p(f_i(\bar{\beta})) = v_p(\alpha_i - \bar{\beta}) \cdot e_i + v_i \geq v_p(\alpha_i - \bar{\alpha}) \cdot e_i + v_i \). The last inequality follows from \( v_p(\alpha_i - \bar{\beta}) \geq l = v_p(\alpha_i - \bar{\alpha}) \).

From the above two paragraphs we get \( v_p(f(\bar{\beta})) \geq k \). Hence, \( f(\bar{\beta}) \equiv 0 \mod p^k \). \( \square \)

Now we define a notion of “neighborhood” of a \( \mathbb{Z}_p \)-root of \( f \).

**Definition 18** (neighborhood). For \( i \in [n] \), \( k > d(\Delta+1) \), we define the neighborhood \( S_{k,i} \) of \( \alpha_i \mod p^k \) to be the set of all those roots of \( f \mod p^k \) which are close to the \( \mathbb{Z}_p \)-root \( \alpha_i \) of \( f \). Formally,

\[
S_{k,i} := \{ \bar{\alpha} \in \mathbb{Z}/(p^k) \mid v_p(\bar{\alpha} - \alpha_i) > \Delta + 1, f(\bar{\alpha}) \equiv 0 \mod p^k \}.
\]

The notion of representative root was first given in [25]. Below we discover its new properties which will lead us to an understanding of length of a representative root, which in turn will give us the size of a neighborhood contributing to \( N_k(f) \).

**Theorem 19** (representative root is a neighborhood). Let \( k > d(\Delta+1) \) and let

\[
a := a_0 + pa_1 + p^2a_2 + \cdots + p^{l-1}a_{l-1} + p^l \ast
\]

be a representative root of \( f(x) \mod p^k \). Define the \( \mathbb{Z}_p \)-root reduction \( \bar{\alpha}_i := \alpha_i \mod p^k \), for all \( i \in [n] \). Fix an \( i \in [n] \), then:

1. The length of \( a \) is large. Formally, \( l > \Delta + 1 \).

2. If \( \bar{\alpha}_i \in a \), then \( \bar{\alpha}_j \notin a \) for all \( j \neq i, j \in [n] \). (This means, using Lemma 15, \( a \) has a uniquely associated \( \mathbb{Z}_p \)-root.)

3. If \( a \) contains \( \bar{\alpha}_i \) then it also contains the respective neighborhood. In fact, if \( \bar{\alpha}_i \in a \), then \( S_{k,i} = a \).

**Proof.** (1) Consider \( \bar{\alpha} := a_0 + pa_1 + \cdots + p^{l-1}a_{l-1} \). By Lemma 15, there exists a unique \( s \in [n] \) such that \( v_p(\bar{\alpha} - \alpha_s) > \Delta + 1 \). Suppose \( l \leq \Delta + 1 \). Then, \( v_p(\bar{\alpha} + p^{\Delta+1} - \alpha_s) = \Delta + 1 \). As, \( \bar{\alpha}' := (\bar{\alpha} + p^{\Delta+1}) \) is also in \( a \), it again has to be close to a unique \( \alpha_s \), with \( s \neq t \in [n] \) such that \( v_p(\bar{\alpha}' - \alpha_s) > \Delta + 1 \). In other words, \( \alpha_s + p^{\Delta+1} \equiv \bar{\alpha} + p^{\Delta+1} \equiv \alpha_i \mod p^{\Delta+2} \). Thus, \( v_p(\alpha_s - \alpha_i) = \Delta + 1 > \Delta/2 \), contradicting Fact 12. This proves \( l > \Delta + 1 \).

(2) Consider distinct \( \bar{\alpha}_i, \bar{\alpha}_j \in a \). Then, by the definition of \( a \), we have \( v_p(\bar{\alpha}_i - \bar{\alpha}_j) \geq l > \Delta + 1 > \Delta/2 \), contradicting Fact 12. Thus, there is a unique \( i \).
(3) Suppose there exists a neighborhood element $\beta \notin a$, satisfying the conditions $v_p(\alpha_i - \beta) > \Delta + 1$ and $f(\beta) \equiv 0 \mod p^k$. Let $j$ be the index of the first coordinate where $\beta$ and $a$ differ; so, $j < l$ since $\beta \notin a$. Clearly, $j > \Delta + 1$; otherwise, since $\alpha_i \in a$ and $\beta \notin a$, we deduce $v_p(\alpha_i - \beta) = j \leq \Delta + 1$, which is a contradiction.

By $v_p(\alpha_i - \beta) = j > \Delta + 1$ and Lemma 17, we get that every element in $\beta + p^j \mathbb{Z}$ is a root of $f(x) \mod p^k$, and consequently each element in $a_0 + pa_1 + p^2a_2 + \cdots + p^{j-1}a_{j-1} + p^j \mathbb{Z}$ is a root of $f(x) \mod p^k$, which contradicts that $a$ is a representative root (because $j < l$; see Definition 4). Thus, $\beta \in a$, implying $S_{k,i} \subseteq a$.

Conversely, consider $\alpha \in a$. Then, as before, $v_p(\alpha - \alpha) \geq l > \Delta + 1$, implying $\alpha \in S_{k,i}$. So, $S_{k,i} \supseteq a$. □

Next, we get the expression for the length of a representative root.

**Theorem 20.** For $k > d(\Delta + 1)$, the representative roots of $f(x) \mod p^k$ are in a one-to-one correspondence with $\mathbb{Z}_p$-roots of $f$. Moreover, the length of the representative root $a$, corresponding to $\alpha_i$, is $l_{i,k} := \lceil (k - v_i)/e_i \rceil$.

**Proof.** By Proposition 3, every root of $f \mod p^k$ is in exactly one of the representative roots. So each reduced $\mathbb{Z}_p$-root $\alpha_i := a_i \mod p^k$ is in a unique representative root. Thus, by parts (2) and (3) of Theorem 19, we get the one-to-one correspondence as claimed.

Consider a $p$-adic integer $\alpha$ with $v_p(\alpha - \alpha_i) := l_\alpha > \Delta$. We have the following equivalences:

$$
\alpha \in a \iff v_p(f(\alpha)) \geq k \iff v_p((\alpha - \alpha_i)^{e_i} \cdot f_i(\alpha)) \geq k \iff e_i l_\alpha + v_i \geq k \quad \text{(by Lemma 16)}
$$

$$
\iff l_\alpha \geq \lceil (k - v_i)/e_i \rceil = l_{i,k}.
$$

Write the representative root corresponding to $\alpha_i$ as $a := a_0 + pa_1 + p^2a_2 + \cdots + p^{l-1}a_{l-1} + p^{l} \mathbb{Z}$. Clearly, $l = \min\{l_\alpha \mid \alpha \in a\} \geq l_{i,k}$. Note that if $l > l_{i,k}$ then by the equivalences we could reduce the length $l$ of the representative root $a$, which is a contradiction. Thus, $l = l_{i,k}$. □

### 3.3. Formula for $N_k(f)$ — Proof of Corollary 2.

For large enough $k$, the previous section gives us an easy way to count the roots. In fact, we have the following simple formula for $N_k(f)$.

**Theorem 21** (roots mod $p^k$). For $k > d(\Delta + 1)$, $N_k(f) = \sum_{i \in [n]} p^{k - \lceil (k - v_i)/e_i \rceil}$, where clearly $v_i, e_i$ and $n$ (as in Section 2.2) are independent of $k$.

**Proof.** Fix $i \in [n]$ and $k > d(\Delta + 1)$. By Theorem 20 we get that in the unique representative root $a$, corresponding to $\alpha_i \mod p^k$, the $(k - \lceil (k - v_i)/e_i \rceil)$-many higher-precision coordinates could be set arbitrarily from $[0, \ldots, p - 1]$ (while the rest, the lower-precision ones, are fixed). That gives us the count via contribution for each $i \in [n]$. Moreover, the sum over neighborhoods, for each $i \in [n]$, gives us exactly $N_k(f)$.

Also, note that if $n = 0$ then the count $N_k(f)$ is equal to 0. □

**Proof of Corollary 2.** Theorem 21 gives a closed form expression for $N_k(f)$, when

$$
k \geq k_0 := d(\Delta + 1) + 1 \leq d(2d - 1)(\log_p C + \log_p d) + 1.
$$
For the other part, note the discriminant $D(f)$ is not equal to 0 if and only if $f$ is squarefree. In the squarefree case $e_i = 1$, for all $i \in [n]$. By Theorem 21, $N_k(f) = \sum_{i \in [n]} p^{\nu_i}$, which is independent of $k$. □

3.4. Computing Poincaré series — Proof of Theorem 1. Building upon the ideas of the previous sections, we will show how to deterministically compute Poincaré series $P(t) = \sum_{k=0}^{\infty} N_k(f)(p^{-1}t)^k$ associated to the input $f(x)$ efficiently, thereby proving Theorem 1. Before that, we need some notation:

Set $k_0 := d(\Delta + 1) + 1$ so we know by Theorem 21 that for $k \geq k_0$, $N_k(f) = \sum_{i=1}^{n} N_{k,i}(f)$, where $N_{k,i}(f) := p^{k-[\nu_i(k)]/e_i}$. For each $i \in [n]$, define $k_i$ to be the least integer such that $k_i \geq k_0$ and $(k_i-\nu_i)/e_i$ is an integer. Then, Poincaré series $P(t)$ can be partitioned into finite and infinite sums as

$$P(t) = P_0(t) + \sum_{i=1}^{n} P_i(t),$$

where

$$P_i(t) := \sum_{k=k_i}^{\infty} N_{k,i}(f) \cdot (p^{-1}t)^k \quad \text{and} \quad P_0(t) := \left( \sum_{k=0}^{k_0-1} N_k(f) \cdot (p^{-1}t)^k \right) + \sum_{i=1}^{n} \sum_{k=k_0}^{k_i-1} N_{k,i}(f) \cdot (p^{-1}t)^k.$$

We now compute the multiplicity $e_i$ by viewing it as the step that increments the length of the representative root associated to $\alpha_i$ as $k$ keeps growing above $k_0$.

**Lemma 22** (compute $e_i$). We can compute the number of $\mathbb{Z}_p$-roots $n$ of $f$ as well as $k_i$, $\nu_i$, and $e_i$, for each $i \in [n]$, in deterministic $\text{poly}(d, \log C + \log p)$-time.

**Proof.** By Theorem 7, we get all representative roots of $f \mod p^k$ implicitly in the form of maximal split ideals (for brevity, we call these split ideals). By Lemma 6, the length of a split ideal is also the length of all representative roots represented by it and the degree is the number of representative roots represented by it. Since, by Theorem 20, $n$ is also the number of representative roots of $f \mod p^k$ for $k \geq k_0$, we run the algorithm of Theorem 7 for $k = k_0$ and sum up the degree of all split ideals obtained, to get $n$.

Suppose the split ideal $I$ we find contains a representative root $\alpha$ of $f \mod p^k$ corresponding to $\alpha_i$, with $k_i$ as defined before. How do we compute $k_i$? By Theorem 20, the length of $\alpha$, when $k = k_i$, is $l_{i,k_i} = (k_i - \nu_i)/e_i$. Now, for all $k = k_i + 1, k_i + 2, \ldots, k_i + e_i$, the length $l_{i,k}$ remains equal to $l_{i,k_i} + 1$, while for the next $k = k_i + e_i + 1$, $l_{i,k}$ increments by one.

So we run the algorithm of Theorem 7 for several $k \geq k_0$. When we find the length incrementing by one, namely, at the two values $k = k_i + 1$ and $k = k_i' := k_i + 1 + e_i$, then we have found $e_i$ (and $k_i$). From the equation, $k_i - \nu_i = e_i \cdot l_{i,k_i}$, we also find $\nu_i$.

Suppose the split ideal $I$ we find contains two representative roots $\alpha$ and $\beta \mod p^k$, corresponding to $\mathbb{Z}_p$-roots $\alpha_i$ and $\alpha_j$ respectively, such that $e_i \neq e_j$ (without loss of generality, say, $e_i < e_j$). In this case, even if $\alpha$ and $\beta$ have the same length, when $k = k_i$, they will evolve to different length representative roots when we go to a “higher-precision” arithmetic mod $p^{k_i + 1 + e_i}$ (by the formula in Theorem 20). So $\alpha, \beta$ must lie in different length split ideals, say, $I_a$ and $I_b$ respectively.

Now, for another representative root $\gamma$ in $I_a$, say corresponding to $\alpha_s$, we have $e_i = e_s$ and hence $\nu_i = \nu_s$. By computing $e_i$ and $\nu_i$ as before, now using the length of $I_a$ and $I_a$, we compute $e_s$ and $\nu_s$
(and $k_c$) for every $c$ in $I_a$. Since, by Lemma 6, the degree of $I_a$ is the number of such representative roots in $I_a$, we can compute $n$; moreover, we get $k_i, v_i, e_i$ for all $i \in [n]$.

Clearly, we need to run the algorithm of Theorem 7 at most $2 \max_{i \in [n]} |e_i| = O(d)$ times, to study the evolution of split ideals (implicitly, that of the underlying representative roots). Also $\Delta$ is the logarithm (to base $p$) of the determinant of a Sylvester matrix which gives $\Delta = O(d \cdot (\log_p C + \log_p d))$. So, the algorithm runs in polynomial time as claimed. \hfill $\square$

Now we prove that the infinite sums $P_i(t)$ are formally equal to rational functions of $t = p^{-s}$.

**Lemma 23** (infinite sums are rational). For each $i \in [n]$, the series $P_i(t)$ is a rational function of $t$ as

$$P_i(t) = \frac{t^{k_i} \cdot (p - t(p - 1) - t^{e_i})}{p^{(k_i - v_i)/e_i} \cdot (1 - t) \cdot (p - t^{e_i})}.$$

**Proof.** Recall that $P_i(t) = \sum_{k=k_i}^{\infty} N_{k,i}(f) \cdot (p^{-1}t)^k$. For simplicity write $T := p^{-1}t$ and define an integer $\delta_i := k_i - (k_i - v_i)/e_i$. Now $P_i$ can be rewritten using residues mod $e_i$ as

$$P_i(t) = \sum_{l=k_i}^{k_i+e_i-1} \sum_{k=0}^{\infty} N_{l+ke_i,i}(f) \cdot T^{l+ke_i}.$$ 

For simplicity take $l = k_i$ and consider the sum, $\sum_{k=0}^{\infty} N_{k_i+ke_i,i}(f) \cdot T^{k_i+ke_i}$. We find that $N_{k_i,i}(f) = p^{\delta_i}$, $N_{k_i+e_i,i}(f) = p^{\delta_i+1}$, $N_{k_i+2e_i,i}(f) = p^{\delta_i+2}$, and so on. Hence, $\sum_{k=0}^{\infty} N_{k_i+ke_i,i}(f) \cdot T^{k_i+ke_i} = p^{\delta_i} \cdot T^{k_i} \cdot [1 + p^{\delta_i+1} \cdot (p^{\delta_i+2} \cdot \cdots)] = p^{\delta_i} \cdot T^{k_i} / (1 - p^{\delta_i} \cdot T^{e_i})$. So

$$P_i(t) = \frac{p^{\delta_i} \cdot T^{k_i}}{1 - p^{\delta_i} \cdot T^{e_i}} + \frac{p^{\delta_i+1} \cdot T^{k_i+1}}{1 - p^{\delta_i+1} \cdot T^{e_i}} + \cdots + \frac{p^{\delta_i+e_i-1} \cdot T^{k_i+e_i-1}}{1 - p^{\delta_i+e_i-1} \cdot T^{e_i}} = \frac{p^{\delta_i} \cdot T^{k_i}}{1 - p^{\delta_i} \cdot T^{e_i}} \cdot \left(1 + T \cdot \frac{1 - (pT)^{\delta_i-1}}{1 - pT} \right).$$

Putting $T = t/p$ and $\delta_i = k_i - (k_i - v_i)/e_i$ we get

$$P_i(t) = \frac{t^{k_i} \cdot (p - t(p - 1) - t^{e_i})}{p^{(k_i - v_i)/e_i} \cdot (1 - t) \cdot (p - t^{e_i})} \cdot \left(1 + T \cdot \frac{1 - (pT)^{\delta_i-1}}{1 - pT} \right).$$

Now we are in a position to prove our main theorem.

**Proof of Theorem 1.** Recall $P(t) = P_0(t) + \sum_{i=1}^{n} P_i(t)$. We first compute $P_0(t)$, which is the sum of two polynomials in $t$, namely,

$$Q_1(t) := \sum_{j=0}^{k_0-1} N_j(f) (p^{-1}t)^j \quad \text{and} \quad Q_2(t) := \sum_{i=1}^{n} \sum_{l=k_0}^{k_i-1} N_{l,i}(f) (p^{-1}t)^l,$$

both of degree $O(d \Delta)$. By a standard determinant or Sylvester matrix calculation one shows $d \Delta \leq O(d^2 \cdot (\log_p C + \log_p d))$. \hfill $\square$
We can compute the polynomial \( Q_1(t) \) in deterministic poly\((d, \log C + \log p)\)-time by calling the root-counting algorithm of [24] (Theorem 7) \( k_0 - 1 \) times, getting each \( N_j(f) \), for \( j = 1, \ldots, k_0 - 1 \) (note: \( N_0(f) := 1 \)).

Polynomial \( Q_2(t) \) is a sum of \( n \leq d \) polynomials, each with \( k_i - k_0 \leq d \) many simple terms. Using Lemma 22, we can compute each \( \nu_i, e_i \), hence, \( N_{l,i}(f) \). So, computation of \( Q_2 \) again takes time poly\((d, \log C + \log p)\).

Lemma 23 gives us the rational form expression for \( P_i(t) \), for each \( i \in \mathbb{N} \). So, using Lemma 22 we can compute the Poincaré series

\[
P(t) = P_0(t) + \sum_{i=1}^{n} \frac{t^{k_i}(p - t(p - 1) - t^{e_i})}{p^{(k_i - \nu_i)/e_i}(1 - t)(p - t^{e_i})}
\]

in deterministic poly\((d, \log C + \log p)\)-time.

By inspecting the above expression, the degree of the denominator \( B(t) \) is \( 1 + \sum_{i=1}^{n} e_i = O(d) \). The degree of the numerator \( A(t) \) is \( \leq k_0 + 2d \leq O(d^2 \cdot (\log_p C + \log_p d)) \). \( \square \)

4. Conclusion and open questions

We presented the first complete solution to the problem of computing Igusa’s local zeta function for any given integral univariate polynomial and a prime \( p \). Indeed, our methods work for given \( f \in \mathbb{Z}_p[x] \) (with \( f \) having computable representation) as our proof for integral \( f \) goes via considering its factorization over \( \mathbb{Z}_p \) (Section 2.2).

We also found an explicit closed-form expression for \( N_k(f) \) and efficiently computed the explicit parameters involved therein, which could be used to compute Greenberg’s constants associated with a univariate \( f \) and a prime \( p \). Greenberg’s constants appear in a classical theorem of Greenberg [29, Theorem 1] which is a generalization of Hensel’s lemma to several \( n \)-variate polynomials. We hope that our methods for the one variable case could be generalized to compute Greenberg’s constants for the \( n \) variable case to give an effective version of Greenberg’s theorem.

We also hope that our methods extend computing Igusa’s local zeta function from characteristic zero (\( \mathbb{Z}_p \)) to positive characteristic (\( \mathbb{F}_p[[T]] \)) at least if some standard restrictions are imposed on the characteristic, for example, \( p \) is “large enough”. This is supported by the fact that the root counting algorithm of [24] also extends to \( \mathbb{F}[[T]] \) for a field \( \mathbb{F} \).

The following important open questions need to be addressed:

1. A natural question to study is whether we could generalize our method to compute Igusa’s local zeta function for \( n \)-variate integral polynomials (say, \( n = 2 \)). Note that for growing \( n \) this problem is at least #P-hard [26].

2. A related problem is of counting roots of \( n \)-variate polynomials mod prime power \( p^k \). We know an efficient quantum algorithm mod \( p \) for \( n = 2 \) due to Kedlaya [37]. Kedlaya further asks, if we can reduce the problem of counting points mod \( p^k \) to counting points mod \( p \) for fixed \( k \) and \( n = 2 \). This question has affirmative answer known only for variable-separated curves due to Robelle et al. [55].
(3) Following up the problem of point counting on curves for constant $k$, we ask another important related open question — how to find a single point on curves mod $p^k$ efficiently. It has an application in factoring a univariate $f(x) \mod p^k$ [25]. Can we efficiently reduce finding a single point mod $p^k$ to finding a single point mod $p$, even for fixed $k$ and $n = 2$?

Acknowledgements

We thank anonymous reviewers for their helpful comments and pointing out relevant references to improve the draft of the paper. In particular we thank them for their suggestion which greatly improved the conclusion section and for pointing out a connection to Greenberg’s work. We thank Kiran Kedlaya for pointing out some minor corrections and asking a relevant open question (Section 4, open question (2)) during the conference ANTS ’20. Nitin Saxena thanks the funding support from DST (DST/SJF/MSA-01/2013-14) and N. Rama Rao Chair.

First published 2020.
The Algorithmic Number Theory Symposium (ANTS), held biennially since 1994, is the premier international forum for research in computational and algorithmic number theory. ANTS is devoted to algorithmic aspects of number theory, including elementary, algebraic, and analytic number theory, the geometry of numbers, arithmetic algebraic geometry, the theory of finite fields, and cryptography.

This volume is the proceedings of the fourteenth ANTS meeting, which took place 29 June to 4 July 2020 via video conference, the plans for holding it at the University of Auckland, New Zealand, having been disrupted by the COVID-19 pandemic. The volume contains revised and edited versions of 24 refereed papers and one invited paper presented at the conference.

TABLE OF CONTENTS

Commitment schemes and diophantine equations — José Felipe Voloch 1
Supersingular curves with small noninteger endomorphisms — Jonathan Love and Dan Boneh 7
Cubic post-critically finite polynomials defined over \( \mathbb{Q} \) — Jacqueline Anderson, Michelle Manes and Bella Tobin 23
Faster computation of isogenies of large prime degree — Daniel J. Bernstein, Luca De Feo, Antonin Leroux and Benjamin Smith 39
On the security of the multivariate ring learning with errors problem — Carl Bootland, Wouter Castryck and Frederik Vercauteren 57
Two-cover descent on plane quartics with rational bitangents — Nils Bruin and Daniel Lewis 73
Abelian surfaces with fixed 3-torsion — Frank Calegari, Shiva Chidambaram and David P. Roberts 91
Lifting low-gonal curves for use in Tuitman’s algorithm — Wouter Castryck and Floris Vermeulen 109
Simultaneous diagonalization of incomplete matrices and applications — Jean-Sébastien Coron, Luca Notarnicolà and Gabor Wiese 127
Hypergeometric \( L \)-functions in average polynomial time — Edgar Costa, Kiran S. Kedlaya and David Roe 143
Genus 3 hyperelliptic curves with CM via Shimura reciprocity — Bogdan Adrian Dina and Sorina Ionica 161
A canonical form for positive definite matrices — Mathieu Dutour Sikirić, Anna Haensch, John Voight and Wessel P.J. van Woerden 179
Computing Igusa’s local zeta function of univariates in deterministic polynomial-time — Ashish Dwivedi and Nitin Saxena 197
Computing endomorphism rings of supersingular elliptic curves and connections to path-finding in isogeny graphs — Kirsten Eisenträger, Sean Hallgren, Chris Leonardi, Travis Morrison and Jennifer Park 215
New rank records for elliptic curves having rational torsion — Noam D. Elkies and Zev Klagsbrun 233
The nearest-colattice algorithm: Time-approximation tradeoff for approx-CVP — Thomas Espitau and Paul Kirchner 251
Cryptanalysis of the generalised Legendre pseudorandom function — Novak Kaluža, Thorsten Kleinjung and Dušan Kostić 267
Counting Richelot isogenies between superspecial abelian surfaces — Toshiyuki Katsura and Katsuyuki Takashima 283
Algorithms to enumerate superspecial Howe curves of genus 4 — Momonari Kudo, Shushi Harashita and Everett W. Howe 301
Divisor class group arithmetic on \( C_{3,4} \) curves — Evan MacNeil, Michael J. Jacobson Jr. and Renate Scheidler 317
Reductions between short vector problems and simultaneous approximation — Daniel E. Martin 335
Computation of paramodular forms — Gustavo Rama and Gonzalo Tornaría 353
An algorithm and estimates for the Erdős–Selfridge function — Brianna Sorenson, Jonathan Sorenson and Jonathan Webster 371
Totally \( p \)-adic numbers of degree 3 — Emerald Stacy 387
Counting points on superelliptic curves in average polynomial time — Andrew V. Sutherland 403
