ON THE NUMBER OF PRIMITIVE PYTHAGOREAN TRIANGLES WITH AREA LESS THAN n

Roy E. Wild

1. Introduction. In the preceding paper Lambek and Moser have shown that if $P_a(n)$ is the number of primitive Pythagorean triangles with area less than n then

(1) $$P_a(n) = c\,n^{1/2} + O(n^{1/3}),$$

where

$$c = \frac{\Gamma^2(1/4)}{2^{1/2}\pi^{5/2}}.$$

They conjecture that

(2) $$P_a(n) = c\,n^{1/2} - c'n^{1/3} + o(n^{1/3}),$$

and on the basis of a table due to Miksa they find

(3) $$c' \approx .295.$$

Our purpose here is to show that

(4) $$P_a(n) = c\,n^{1/2} - c'n^{1/3} + O(n^{1/4}\ln n),$$

where

(5) $$c' = -\frac{\zeta(1/3)\,(1+2^{-1/3})}{\zeta(4/3)\,(1+4^{-1/3})} \approx .297.$$

In the paper by Lambek and Moser, the problem of calculating $P_a(n)$ has been reduced to that of counting the number of lattice points $L(n)$ in the region R_1 defined by

Received December 3, 1953. The author is grateful to Professor E. G. Straus for calling his attention to the problem treated in this paper, and for making valuable suggestions and criticisms.

Pacific J. Math. 5 (1955), 85-91

$$(6)\qquad xy(y^2-x^2)<n,\quad y>x>0.$$

They obtain

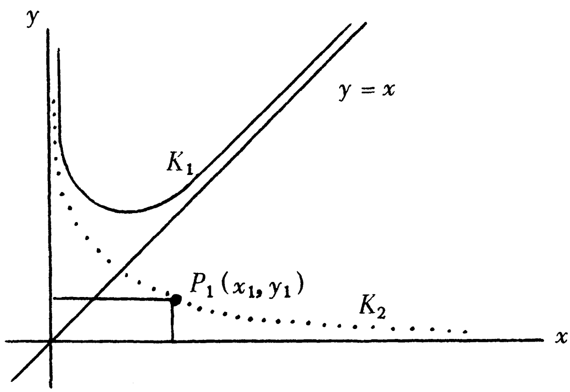
$$(7)\qquad L(n)=\frac{\Gamma^2(1/4)}{2^{5/2}\pi^{1/2}}\,n^{1/2}+O(n^{1/3}).$$

We shall obtain, in place of (7),

$$(8)\qquad L(n)=\frac{\Gamma^2(1/4)}{2^{5/2}\pi^{1/2}}\,n^{1/2}+(1+2^{-1/3})\,\zeta(1/3)\,n^{1/3}+O(n^{1/4}).$$

2. **Proof of (8).** Following is the graph of

$$(9)\qquad K_1:xy(y^2-x^2)=n.$$



From K_1 we obtain the curve K_2 by replacing y in K_1 by $y+x$ to get

$$(10)\qquad K_2:xy(x+y)(2x+y)=n.$$

This transformation preserves the area and number of lattice points in R_1. So we count the lattice points in R_2 defined by

$$(11)\qquad xy(x+y)(2x+y)<n,\quad x>0,\ y>0.$$

By Cardan's formulas, we obtain, from (10),

$$(12)\qquad x=\left(\frac{n}{4y}\right)^{1/3}\left\{\left[1+\left(1-\frac{y^8}{108n^2}\right)^{1/2}\right]^{1/3}+\left[1-\left(1-\frac{y^8}{108n^2}\right)^{1/2}\right]^{1/3}\right\}-\frac{y}{2}$$

and

(13) $$y=\left(\frac{n}{2x}\right)^{1/3}\left\{\left[1+\left(1-\frac{4x^8}{27n^2}\right)^{1/2}\right]^{1/3}+\left[1-\left(1-\frac{4x^8}{27n^2}\right)^{1/2}\right]^{1/3}\right\}-x.$$

In (13) take

$$x=x_1=\left(\frac{27}{4}\right)^{1/8}n^{1/4},$$

say, so that

$$y=y_1=\left(\left(\frac{64}{3}\right)^{1/8}-\left(\frac{27}{4}\right)^{1/8}\right)n^{1/4},$$

thus determining the point $p_1:(x_1,y_1)$ on K_2.

Let square brackets denote the greatest integer function. Then from the figure we have

(14) $$L(n)=\sum_{x=1}^{[x_1]}[y]+\sum_{y=1}^{[y_1]}[x]-[x_1][y_1]-l(n),$$

where $l(n)$ is the number of lattice points on K_2. Now $l(n)$ is zero unless n is an integer N. For nonintegral n we can prove (8). For small positive ϵ we obtain (8) for, say, $N+\epsilon$ and $N-\epsilon$, so that trivially

(15) $$l(n)=O(n^{1/4})\text{ for all real } n.$$

By definition,

(16) $$[x_1]=O(n^{1/4}),\ [y_1]=O(n^{1/4}),$$

so that we may drop the brackets in (14) with an error $O(n^{1/4})$. Then, by use of (15) and (16), (14) becomes

(17) $$L(n)=\sum_{x=1}^{[x_1]}y+\sum_{y=1}^{[y_1]}x-x_1y_1+O(n^{1/4}).$$

We shall estimate the above sums by the Euler-Maclaurin summation formula in the form:

$$(18)\qquad \sum_{k=a}^{b} f(k) = \int_a^b f(x)\,dx + \frac{1}{2} f(b) + \frac{1}{2} f(a) + \int_a^b \left(x - [x] - \frac{1}{2}\right) f'(x)\,dx.$$

We obtain from (17):

$$(19)\qquad L(n) = \int_1^{[x_1]} y\,dx + \int_1^{[y_1]} x\,dy - x_1 y_1 + O(n^{1/4})$$

$$+ \frac{1}{2} y([x_1]) + \frac{1}{2} y(1) + \frac{1}{2} x([y_1]) + \frac{1}{2} x(1)$$

$$+ \int_1^{[x_1]} \left(x - [x] - \frac{1}{2}\right) \frac{dy}{dx}\,dx + \int_1^{[y_1]} \left(y - [y] - \frac{1}{2}\right) \frac{dx}{dy}\,dy.$$

In the first two terms of (19), we may drop brackets with an error of $O(n^{1/4})$, so that, if A represents the entire area of R_2, we may replace the first three terms of (19) by

$$(20)\qquad A - \int_0^1 y\,dx - \int_0^1 x\,dy + O(n^{1/4}).$$

Now from (12) and (13) we have

$$(21)\qquad x = (n/4y)^{1/3}\,(2^{1/3} + O(y^{8/3}/n^{2/3})) + O(y)$$

$$= (n/2y)^{1/3} + O(y^{7/3}/n^{1/3}) + O(y),$$

and similarly

$$(22)\qquad y = (n/x)^{1/3} + O(x^{7/3}/n^{1/3}) + O(x).$$

Substituting in (20), we obtain

$$(23)\qquad A - 3n^{1/3}/2 + O(n^{-1/3}) + O(1)$$

$$- 3n^{1/3}/2^{4/3} + O(n^{-1/3}) + O(1) + O(n^{1/4})$$

$$= A - \frac{3}{2}(1 + 2^{-1/3})n^{1/3} + O(n^{1/4}).$$

The fifth and seventh terms of (19) are $O(n^{1/4})$. Also

$$\frac{1}{2}y(1) = \frac{1}{2}n^{1/3} + O(1) \text{ and } \frac{1}{2}x(1) = n^{1/3}/2^{4/3} + O(1).$$

Differentiating the expansions of x and y in (21) and (22) we obtain

$$(24) \qquad dx/dy = -n^{1/3}y^{-4/3}/3 \cdot 2^{1/3} + O(y^{4/3}/n^{1/3}) + O(1),$$

$$(25) \qquad dy/dx = -n^{1/3}x^{-4/3}/3 + O(x^{4/3}/n^{1/3}) + O(1).$$

We now rewrite the last two terms of (19) as

$$(26) \qquad \int_1^{n^{1/8}} \left(x - [x] - \frac{1}{2}\right)\frac{dy}{dx}\,dx + \int_{n^{1/8}}^{[x_1]} \left(x - [x] - \frac{1}{2}\right)\frac{dy}{dx}\,dx$$

$$+ \int_1^{n^{1/8}} \left(y - [y] - \frac{1}{2}\right)\frac{dx}{dy}\,dy + \int_{n^{1/8}}^{[y_1]} \left(y - [y] - \frac{1}{2}\right)\frac{dx}{dy}\,dy.$$

Since $|dy/dx|$ is monotonic decreasing, we have, by the second mean value theorem for integrals, and (25),

$$(27) \qquad \int_{n^{1/8}}^{[x_1]} \left(x - [x] - \frac{1}{2}\right)\frac{dy}{dx}\,dx = \left.\frac{dy}{dx}\right|_{x=n^{1/8}} \int_{n^{1/8}}^{h} \left(x - [x] - \frac{1}{2}\right)dx$$

$$= O(n^{1/6})\,O(1) = O(n^{1/6}).$$

Similarly

$$(28) \qquad \int_{n^{1/8}}^{[y_1]} \left(y - [y] - \frac{1}{2}\right)\frac{dx}{dy}\,dy = O(n^{1/6}).$$

Substituting (24) and (25) in the remaining terms of (26) yields

$$(29) \int_1^{n^{1/8}} \left(x - [x] - \frac{1}{2}\right)\frac{dy}{dx}\,dx = -\frac{n^{1/3}}{3}\int_1^{n^{1/8}} \left(x - [x] - \frac{1}{2}\right)x^{-4/3}\,dx + O(1)$$

$$= -\frac{n^{1/3}}{3}\int_1^{\infty} \left(x - [x] - \frac{1}{2}\right)x^{-4/3}\,dx + \frac{n^{1/3}}{3}\int_{n^{1/8}}^{\infty} \left(x - [x] - \frac{1}{2}\right)x^{-4/3}\,dx + O(1)$$

$$= -\frac{n^{1/3}}{3}\int_1^{\infty} \left(x - [x] - \frac{1}{2}\right)x^{-4/3}\,dx + O(n^{1/6}),$$

and similarly

$$(30)\qquad \int_1^{n^{1/8}} \left(y-[y]-\frac{1}{2}\right)\frac{dx}{dy}\,dy = -\frac{n^{1/3}}{3\cdot 2^{1/3}}\int_1^{\infty}\left(y-[y]-\frac{1}{2}\right)y^{-4/3}\,dy$$

$$+O(n^{1/6}).$$

Collecting the preceding results, we have

$$(31)\qquad L(n) = A - \frac{3}{2}(1+2^{-1/3})n^{1/3} + O(n^{1/4}) + O(n^{1/4}) + n^{1/3}/2 + O(1)$$

$$+ n^{1/3}/2^{4/3} + O(1) + (1+2^{-1/3})c_1 n^{1/3} + O(n^{1/6})$$

$$= A - (1+2^{-1/3})(1-c_1)n^{1/3} + O(n^{1/4}),$$

where

$$(32)\qquad c_1 = \int_1^{\infty}\left(x-[x]-\frac{1}{2}\right)dx^{-1/3} = \zeta(1/3)+1.$$

Now A is the area of R_2 and therefore the area of R_1. Its value as calculated by Lambek and Moser is

$$(33)\qquad A = c_2\, n^{1/2},\quad c_2 = \frac{\Gamma^2(1/4)}{2^{5/2}\pi^{1/2}}\ .$$

Substitution from (32) and (33) in (31) yields (8).

3. Derivation of (4). Let $c_3 = -(1+2^{-1/3})\,\zeta(1/3)$, so that (31) becomes

$$(34)\qquad L(n) = c_2 n^{1/2} - c_3 n^{1/3} + O(n^{1/4}).$$

Following the notation of Lambek and Moser, we can write (34) as

$$(35)\qquad L(Rt) = c_2 t^2 - c_3 t^{4/3} + O(t).$$

From their equation (14) we have

$$(36)\qquad L'(Rt) = \sum_{i\geq 1} \mu(i)\left\{c_2\,\frac{t^2}{i^2} - c_3\,\frac{t^{4/3}}{i^{4/3}} + O(t/i)\right\}$$

$$= \{6c_2/\pi^2 + O(1/t)\}t^2 - \{c_3/\zeta(4/3) + O(1/t^{1/3})\}t^{4/3} + O(t \ln t)$$

$$= \frac{6c_2}{\pi^2}\, t^2 - \frac{c_3}{\zeta(4/3)}\, t^{4/3} + O(t \ln t).$$

Then from their equations (6), (15), and our (36), we have

$$(37) \qquad P_a(n) = \sum_{i \geq 0} (-1)^i \left\{ \frac{6c_2 n^{1/2}}{\pi^2 2^i} - \frac{c_3 n^{1/3}}{\zeta(4/3) 4^{i/3}} + O\left(\frac{n^{1/4}}{4^{i/4}} \ln \frac{n}{4^i} \right) \right\}$$

$$= 4c_2 n^{1/2}/\pi^2 - \frac{c_3 n^{1/3}}{\zeta(4/3)(1 + 4^{-1/3})} + O(n^{1/4} \ln n)$$

$$= c\, n^{1/2} - c' n^{1/3} + O(n^{1/4} \ln n).$$

This is (4).
