MULTIPLICATIVITY OF THE LOCAL HILBERT SYMBOL

RONALD JACOBOWITZ
MULTIPLICATIVITY OF THE LOCAL HILBERT SYMBOL
RONALD JACOBOWITZ

1. Introduction. Let $F$ be a commutative field of characteristic not 2, complete under a discrete, non-archimedean valuation $| |$, with finite residue class field—such a field is often called local—for example, the field of ordinary $p$-adic numbers. For nonzero elements $\alpha, \beta$ of $F$, the Hilbert symbol $(\alpha, \beta)$ is defined to be $+1$ or $-1$ according as the equation $\alpha x^2 + \beta y^2 = 1$ is or is not solvable in $F$. It has such obvious properties as $(\beta, \alpha) = (\alpha, \beta)$, $(\alpha, \beta \gamma) = (\alpha, \beta)$, $(\alpha, -\alpha \beta) = (\alpha, \beta)$; and if at least one of $(\alpha, \beta)$, $(\alpha, \gamma)$ is $+1$, then

\begin{equation}
(\alpha, \beta)(\alpha, \gamma) = (\alpha, \beta \gamma),
\end{equation}

as is easily seen by observing (whether or not $\alpha \in F^2$)

\begin{equation}
(\alpha, \beta) = +1 \text{ if and only if } \beta \in N_{E/F} E, \text{ where } E = F(\alpha^{1/2}).
\end{equation}

These properties are true even without the assumption that $F$ is local; under that assumption, however, the multiplicative property (1) is always true, i.e., $(\alpha, \beta) = (\alpha, \gamma) = -1 \Rightarrow (\alpha, \beta \gamma) = +1$. In [3], Example 63:12, O'Meara derives this result from the study of local quaternion algebras by applying Wedderburn structure theory to tensor products of such algebras. The point of the present paper is to give a direct proof, using only the most elementary facts about non-archimedean valuations (such as found in [3], Chap. 1). Specifically, we shall prove the so-called "second inequality of local class field theory" for quadratic extensions, i.e., $(F^* : N_{E/F} E^*) \leq 2$, where $E$ is an arbitrary quadratic extension of $F$, and $F^*$ and $E^*$ denote, respectively, the nonzero elements of $F$ and $E$; the required property (1) will then follow immediately, because of (2).

2. Proof of the second inequality. Since the ramification number of $E/F$ is at most $2$ ([3], Proposition 13:6), an obvious computation shows that it suffices to prove the

PROPOSITION.

\begin{align*}
(u : N_{E/F} U) &= 1 & \text{if } E/F \text{ is unramified} \\
(u : N_{E/F} U) &\leq 2 & \text{if } E/F \text{ is ramified},
\end{align*}

where $u = \{ \varepsilon \in F | \varepsilon = 1 \}$ and $U = \{ a \in E | | a | = 1 \}$, the units of $F$ and $E$, respectively.

Received February 27, 1963.

187
The proof of the Proposition will be broken up into several steps. First, let \( \pi \) denote a generic prime element (to be specified later) for \( F \), and for each positive rational integer \( n \), define \( u_n = \{ \varepsilon \in u \mid \varepsilon \equiv 1 \pmod{\pi^n} \} \), a subgroup of \( u \). Also define the nonnegative integer \( e \) by \( |\pi|^e = |2| \); thus \( e = 0 \) in the non-dyadic case \( (|2| = 1) \), \( e > 0 \) in the dyadic case \( (|2| < 1) \). We obviously have \( u \supseteq u_1 \supseteq u_2 \supseteq \cdots \supseteq u_2 \supseteq u_{2e+1} \supseteq \cdots \). Furthermore, by Hensel's lemma ([3], Theorem 63:1), \( u_{2e+1} \supseteq u^\beta \subseteq \mathcal{N}^U \) (notation: \( \mathcal{N} = N_{\mathbb{E}/\mathbb{F}} \)), thus we can write \( u \supseteq u_N \supseteq u_{2e} \supseteq \cdots \supseteq u_{2e+1} = \mathcal{N} \); since group-indices multiply, we therefore have

**LEMMA 1.** \((u : \mathcal{N}) = (\mathcal{N} : u_{2e+1})(u_{2e+1} : u_{2e})(u_{2e} : u_{2e-1}) \cdots (u_2 : u_1)(u : u_1)\) .

We next refer to [2], § 5, for a classification of the several types of extensions \( E/F \), namely:

**Non-dyadic:**
- Unramified if \( E = F(\theta^{1/2}) \) with \( |\theta| = 1 \)
- Ramified if \( E = F(\pi^{1/2}) \)

**Dyadic:**
- Unramified if \( E = F((1 + 4\delta)^{1/2}) \) with \( |\delta| = 1 \)
- Ramified ("R-P") if \( E = F(\pi^{1/2}) \)
- Ramified ("R-U") if \( E = F((1 + \pi^{2k+1}\delta)^{1/2}) \) with \( |\delta| = 1 \) and \( 0 \leq k \leq e - 1 \).

Here \( \pi \), of course, denotes some particular prime element for \( F \). In the case we are calling "R-U", recall from [2], p. 454, that \( p = [1 + (1 + \pi^{2k+1}\delta)]/\pi^k \) satisfies \( Np = -\pi\delta \) and hence can (and shall) serve as prime element for \( E \); and in "R-P", we shall take \( p = \pi^{1/2} \) as prime element for \( E \). Let us also write \( o = \{ \alpha \in F \mid |\alpha| \leq 1 \} \), the "integers" of \( F \).

**LEMMA 2.**

\[
\begin{align*}
(u : u_1) & = 1 \quad \text{in the unramified non-dyadic, and} \\
(u : u_N) & \leq 2 \quad \text{in the ramified non-dyadic case}.
\end{align*}
\]

**Proof.** The composite map \( u \xrightarrow{\text{can}} \mathcal{O}^{*} \xrightarrow{\text{can}} \mathcal{O}^{*}/\mathcal{O}^{*}_{\mathbb{E}/\mathbb{F}} \), \( \mathcal{O} \) denoting the residue class field of \( F \), is a multiplicative epimorphism with kernel \( u_1u^{\prime} \), so \( (u : u_1) \leq (u : u_1) = \text{order of } \mathcal{O}^{*}/\mathcal{O}^{*}_{\mathbb{E}/\mathbb{F}} \); since \( \mathcal{O} \) is finite, this order is 1 in the dyadic case, 2 in the non-dyadic. This proves the Lemma except in the unramified non-dyadic case, where we need a sharper estimate; however, in that case, we can apply Proposition
MULTIPLICATIVITY OF THE LOCAL HILBERT SYMBOL

62:1 of [3] (which shows that for any unit \( \varepsilon \) of \( F \), the congruence
\( \varepsilon x^2 + \theta y^2 \equiv 1 \pmod{\pi} \) can be solved in \( \mathfrak{O} \) and Hensel’s lemma to conclude
that the Hilbert symbol \((\varepsilon, \theta)\) is equal to \(+1\) for all \( \varepsilon \) in \( \mathfrak{U} \), hence
\( u = \mathfrak{N} \).

**Lemma 3.** Suppose \( E/F \) is dyadic. Then \((u_{n+1}^{\mathfrak{N}} : u_n^{\mathfrak{N}}) = 1\) in the following cases: Unramified: \( 1 \leq n \leq 2e \)
R-P: \( 1 \leq n \leq 2e - 1 \)
R-U: \( 1 \leq n \leq 2(e - k) - 2 \) and \( 2(e - k) \leq n \leq 2e \).

**Proof.** Our procedure will be, given \( \varepsilon = 1 + \pi^a \alpha \) in \( \mathfrak{U} \) (thus with
\( \alpha \in \mathfrak{O} \)), to construct \( a \) in \( \mathfrak{U} \) with \( \varepsilon \equiv Na \pmod{\pi^{n+1}} \), thus \( \varepsilon/Na \in u_{n+1}^{\mathfrak{N}} \),
thus \( \varepsilon \in u_{n+1}^{\mathfrak{N}} ; \) this will show \( u_n \subseteq u_{n+1}^{\mathfrak{N}} \), hence \( u_n \mathfrak{N} \mathfrak{U} = u_{n+1}^{\mathfrak{N}} \mathfrak{U} \). We consider five cases (note that II and V overlap, which simply means
that either construction will work).

(I) Unramified. Take \( a = 1 + \pi^e \alpha (1 + (1 + 4\delta)^{1/2})/2 \).

(II) R-P or R-U, \( n = 2r \) even, \( 1 \leq r \leq e - 1 \). Recalling that
\( \mathfrak{O} \) is finite of characteristic 2, find \( \beta \in \mathfrak{O} \) with \( \beta^2 \equiv \alpha \pmod{\pi} \), and take
\( a = 1 + \pi^r \beta \).

(III) R-P, \( n = 2r + 1 \) odd, \( 0 \leq r \leq e - 1 \). Find \( \beta \in \mathfrak{O} \) with
\( \beta^2 \equiv -\alpha \pmod{\pi} \), and take \( a = 1 + \pi^r \beta \).

(IV) R-U, \( n = 2r + 1 \) odd, \( 0 \leq r \leq e - k - 2 \). Find \( \beta \in \mathfrak{O} \) with
\( \beta^2 \equiv -\alpha/\delta \pmod{\pi} \), and take \( a = 1 + \pi^r \beta \).

(V) R-U, \( n \geq 2(e - k) \). Take \( a = 1 + \pi^{2(e-k)} \alpha/2 \). We check in
each case that \( a \) belongs to \( \mathfrak{U} \) and \( \varepsilon \equiv Na \pmod{\pi^{n+1}} \).

For the remaining two indices, we have

**Lemma 4.** In R-P, \((u_{2e}^{\mathfrak{N}} : u_{2e+1}^{\mathfrak{N}}) \leq 2\); in R-U,
\((u_{2(e-k)-1}^{\mathfrak{N}} : u_{2(e-k)-1}^{\mathfrak{N}}) \leq 2\).

**Proof.** The first of the two inequalities is easily disposed of by
Proposition 63:4 of [3], which essentially states that \( (u_n : u_{n+1}) = 2 \),
so we turn to the second. Note that (for \( \beta \in \mathfrak{O} \)) \( N(1 + \pi^{2(e-k)-1} \beta) =
1 + \pi^{2(e-k)-1}(2\pi^{-c} \beta - \delta \beta^2) \), and set \( \mathcal{N} = \{N(1 + \pi^{2(e-k)-1} \beta) \mid \beta \in \mathfrak{O} \} \).
Now we may assume \( u_{2(e-k)-1} \) is not a subset of \( u_{2(e-k)-1}^{\mathfrak{N}} \), and so can fix
\( \varepsilon_0 = 1 + \pi^{2(e-k)-1} \alpha_0 \) in \( u_{2(e-k)-1} \) but not in \( u_{2(e-k)-1}^{\mathfrak{N}} \), hence with \( \varepsilon_0 \notin \mathcal{N} \),
hence with \( \alpha_0 \) not of the form \( 2\pi^{-c} \beta - \delta \beta^2 \); then for any \( \varepsilon =
1 + \pi^{2(e-k)-1} \alpha \) in \( u_{2(e-k)-1} \) but not in \( u_{2(e-k)-1}^{\mathfrak{N}} \), we also have \( \alpha \) not of
the form $2\pi^\epsilon \beta - \delta \beta^2$, and since, reading modulo $\pi$, elements of the form $2\pi^\epsilon \beta - \delta \beta^2$ determine an additive subgroup of $\mathfrak{o}$ of index $2$, we can find $\beta_1$ in $\mathfrak{o}$ with $\alpha + \alpha_0 \equiv 2\pi^\epsilon \beta_1 - \delta \beta_1^2 \pmod{\pi}$, so that $\varepsilon \varepsilon_0 \equiv N(1 + \pi^{\epsilon \beta - \delta \beta} \beta_1) \pmod{\pi^{\beta - \delta \beta}}$, i.e., $\varepsilon \in \varepsilon_0 u_{1(e-k)} N \mathfrak{U}$; thus the index $(u_{1(e-k)} - 1 \mathfrak{U} : u_{1(e-k)} N \mathfrak{U})$ is at most $2$. q.e.d.

The proof of the Proposition, and thus the multiplicative property (1), now follows by combining the four Lemmas.

3. **Concluding remarks.** The “first inequality of local class field theory” states $(F^* : NE^*) \geq 2$, and can also be proven directly—cf. [3], Propositions 63:13 and 63:13a. Its significance for us is that each of our index-inequalities in the Proposition and Lemmas 2 and 4 is now seen to be an equality.

As Durfee has shown in [1], the local isometry invariants for quadratic forms can easily be derived once our multiplicative property is known. Similarly, in the more modern, “geometric” treatment given in [3], §58, §63, it is not difficult to reinterpret O’Meara’s quaternion algebra $(\alpha, \beta)$ as a Hilbert symbol, tensor product $\otimes$ as ordinary multiplication, and algebra-similarity $\sim$ as equality; most of the arithmetic results of [3] then follow readily from the multiplicative property (1) and the Hasse theorem that any form in five variables is locally isotropic.
