POLYNOMIALS ORTHOGONAL OVER A DENUMERABLE SET

JACK L. GOLDBERG
POLYNOMIALS ORTHOGONAL OVER A DENUMERABLE SET

J. L. GOLDBERG

This paper concerns itself with characterizing the orthogonality domain and the distribution function for polynomials which satisfy

\[ \phi_{n+1}(x) = (x - a_n)\phi_n(x) - b_n\phi_{n-1}(x) \quad (n \geq 0) \]

with

\[ \phi_{-1}(x) = 0 \quad \text{and} \quad \phi_0(x) = 1 \]

under the restriction \( a_n = 0, \quad b_n > 0 \) (\( n \geq 0 \)) and \( \lim b_n = 0 \).

This extends the results of Dickinson, Pollak and Wannier [6] by replacing their restriction \( \Sigma b_n < \infty \) with the weaker assumption \( \lim b_n = 0 \), by correcting an apparent oversight, and by characterizing the distinction between the cases \( \Sigma b_n < \infty \) and \( \lim b_n = 0 \). In the course of this study we prove some theorems with occur rather naturally and seem of interest in their own right. Our approach owes its origins to ideas expressed in [4] and [6] and our techniques to the product and the series representations for a certain subclass of analytic functions studied by Richards [9] and related to functions characterized by a certain Stieltjes transform and continued fraction expansion.

More specifically; from a theorem of Favard [7] and Shohat [11], equations (1.1) and (1.2) and the assumptions \( a_n \) real and \( b_n > 0 \) (\( n \geq 0 \)) are sufficient to imply that \( \{\phi_n(x)\} \) is a real orthogonal set. Under the additional restrictions \( a_n = 0 \) (\( n \geq 0 \)) and \( \Sigma b_n < \infty \), Dickinson, Pollak and Wannier [6] have shown:

(i) The domain of orthogonality is a bounded denumerable set \( S \), symmetric with respect to \( x = 0 \), with \( x = 0 \) the only non-isolated point.

(ii) The distribution function (unique, after normalization, because of the boundeness of \( S \)) with respect to which the polynomials \( \{\phi_n(x)\} \) are orthogonal, is bounded, nondecreasing and with spectrum (the points of increase) the point set \( S \) of (i). The points \( S \) are the poles of a certain function, meromorphic in \( 1/x \), whose residues are the values of the jumps of the distribution. (This statement appears to require modification because of the possibility of nonzero mass at \( x = 0 \), a

Received June 12, 1964. Research supported in part by a grant from the National Science Foundation.
point of $S$ not a pole. This oversight is examined in some detail below, see Theorem 3 and § 5.)

(iii) The sequence $\{x^n\phi_n(x)\}$ converges to an entire function which is shown to be the denominator of the meromorphic function referred to in (ii).

Later, Carlitz [2], studying polynomials, remotely related to Laguerre polynomials, showed that properties (i) and (ii) hold for the polynomial sets (under a different normalization)

$$g_{n+1}(x) = x g_n(x) - n g_n^0(x) \quad (n \geq 1)$$

where $\gamma > 0$, $g_0(x) = 1$ and $g_1(x) = x$. For these polynomials $\Sigma b_n$ diverges and hence (Corollary 4, below) (iii) is false. Subsequently, Chihara [3, pg. 15] noted, and offered an independent proof of, a theorem implicit in the works of Stieltjes [13], equivalent to the proposition that $\lim b_n = 0$ is necessary as well as sufficient to insure a denumerable spectrum (with $x = 0$ the only limit point) for the distribution relative to $\{\phi_n(x)\}$, $a_n = 0$, $n = 0, 1, \cdots$.

In § 2 we sketch the fundamental theorems of continued fractions and the theory of moments that are pertinent to our work. In § 3 we prove the corrected generalization of the Dickinson, Pollak and Wannier theorem (Theorem 3) and set forth necessary and sufficient conditions that $\lim x^n\phi_n(1/x)$ be entire. Section 4 provides a representation theorem for the class of meromorphic functions relevant to our study and provides us with a means for investigating in § 6, conditions under which mass at $x = 0$ is not present. Finally we offer an example, due essentially to Wall [15] which explicitly contradicts (ii) (without the modification supplied in Theorem 3) but in which (iii) holds. The example is of interest independently of our use.

2. Preliminary theorems and notational conventions. We use this section to set forth those parts of the theory of continued fractions, theory of moments and theory of orthogonal polynomials which bear on the problems with which we wish to concern ourselves. None of these theorems are novel. They are stated in a form suitable for our purposes with their proofs outlined only in such detail that a specific reference may be quoted for their completion.

Consider the class of polynomial sets defined recursively by

$$\phi^{(s)}_{n+1}(x) = x \phi^{(s)}_n(x) - b_{n+s} \phi^{(s)}_{n-s}(x) \quad (n \geq 0)$$

with

$$\phi^{(s)}_0(x) = 0, \quad \phi^{(s)}_1(x) = 1$$
and

\begin{equation}
(2.3) \quad b_n > 0 \quad (n \geq 0).
\end{equation}

We write \( \phi_n^{(s)}(x) \) as \( \phi_s(x) \) and agree in general to omit all zero superscripts. We reserve the use of superscripts in parenthesis for non-negative integers fixed in advance of any argument and never for use as a derivative.

It may be easily seen that \( \{\phi_n^{(s)}(x)\} \) are the successive denominators and \( \{\phi_n^{(s+1)}(x)\} \) the successive numerators (here our convention assures that \( s \) is fixed and the sequences are indexed by \( n \)) of the convergents of

\begin{equation}
(2.4) \quad \frac{1}{1} - \frac{b_{1+s}}{x} - \frac{b_{2+s}}{x} - \cdots - \frac{b_{n+s}}{x} - \cdots.
\end{equation}

Such polynomial sequences have been studied by Dickison [4], [5], Dickinson, Pollak and Wannier [6], and perhaps most completely by Sherman [10], in which more references may be found. We pause to mention the important recursion relationship

\begin{equation}
(2.5) \quad \phi_n^{(s)}(x) = x\phi_{n-1}^{(s-1)}(x) - b_{1+s}\phi_{n-2}^{(s+2)}(x) \quad (n \geq 1),
\end{equation}

which follows from (2.4) but which may be proved independently by induction. If (2.5) is established first, one may observe directly that

\begin{equation}
(2.6) \quad \frac{\phi_{n-1}^{(s+1)}(x)}{\phi_n^{(s)}(x)} = \frac{1}{x} - \frac{b_{1+s}}{x} - \cdots - \frac{b_{n+s-1}\phi_{n-2}^{(s+2)}(x)}{x},
\end{equation}

and hence the equivalence of (2.4) and \( \lim_n \frac{\phi_{n-1}^{(s+1)}(x)}{\phi_n^{(s)}(x)} \). The definitions (2.1) and (2.2), the theorem of Favard-Shohat and the standard properties of real orthogonal polynomials lead to the observations which we state as

**Lemma 1.** All the zeros of the monic polynomials \( \phi_n^{(s)}(x) \) are real and simple. The degree of \( \phi_n^{(s)}(x) \) is precisely \( n \) and \( \phi_n^{(s)}(x) \) is an \((even)\) function if \( n \) is \((even)\). The zeros of \( \phi_n^{(s)}(x) \) and \( \phi_{n-1}^{(s+1)}(x) \) alternate; there is a zero of one polynomial separating two consecutive zeros of the other.

Next consider the sequence \( \{\phi_{n-1}^{(s+1)}(x)/\phi_n^{(s)}(x)\} \). Set \( z = 1/x \) in (2.3) and define \( G^{(s)}(z) \) by

\[ zG^{(s)}(z) = \frac{1}{|1/z|} - \frac{b_{1+s}}{|1/z|} - \frac{b_{2+s}}{|1/z|} - \cdots - \frac{b_{n+s}}{|1/z|} - \cdots. \]

so that after and equivalence transformation
A necessary and sufficient condition that (2.7) be a nonrational meromorphic function is $b_n > 0$ and $\lim b_n = 0$ (see Wall [14; Theorems 54.1 and 54.2]). Hence,

**Theorem 1.** If $\{\phi_n(x)\}$ is defined by (2.1), (2.2) and (2.3) with $\lim b_n = 0$, then for each nonnegative integer $s$.

$$\lim_{n \to \infty} \frac{\phi_{n+s}^{(s+1)}(1/z)}{z\phi_n^{(s)}(1/z)} = G^{(s)}(z).$$

$G^{(s)}(z)$ is a transcendental meromorphic function and the convergence in (2.8) is uniform in compact sets which exclude the poles of $G^{(s)}(z)$.

As a corollary of this theorem we prove the properties of the orthogonality domain listed in (i) of the introduction. (See Chihara [3, pg. 15] for an alternate proof along different lines). Consider an interval $[c, d]$ free of poles of $G^{(s)}(1/x)$. Lemma 1 assures that the zeros of $\phi_n^{(s)}(x)$ and $\phi_{n+1}^{(s)}(x)$ are not common. Hence, Theorem 1 and Hurwitz’s theorem imply that $[c, d]$ is ultimately free of zeros of $\phi_n^{(s)}(x)$. Thus any distribution function for $\{\phi_n^{(s)}(x)\}$ is constant in $[c, d]$, Szegö [12, Theorem 6.1.1]. But the poles of $G^{(s)}(1/x)$ are a bounded set, symmetrically distributed with respect to $x = 0$. Hence, we have proved:

**Corollary 1.** The orthogonality domain for the $\{\phi_n^{(s)}(x)\}$ of Theorem 1 is the bounded, denumerably infinite set of singularities of $G^{(s)}(1/x)$. This set is isolated except at $x = 0$, and symmetric with respect to the origin.

Suppose, by way of a converse, that $S$ is any bounded, denumerably infinite point set with $x = 0$ the only limit point. Suppose the distribution function $\beta(x)$ (bounded and nondecreasing) has $S$ as its spectrum. We normalize $\beta(x)$ and all distribution function considered herein by specifying:

\[(i) \quad \int_{-\infty}^{\infty} d\beta = 1\]

\[(ii) \quad \beta(x) = \frac{1}{2} [\beta(x + 0) + \beta(x - 0)], \quad x \in S.\]

Suppose further that $\beta(-x) = -\beta(x)$ (so that $S$ is symmetric) and that $\{p_n(x)\}$ is the unique set of monic polynomials orthogonal over $S$ with
respect to \( d\beta \). Then the symmetry of \( d\beta \) leads directly to

\[
(2.10) \quad p_{n+i}(x) = xp_n(x) - B_n p_{n-i}(x) \quad (n \geq 0)
\]

with \( p_{-i}(x) = 0 \) and \( p_0(x) = 1 \). This in turn defines the function (Szegö [12, Theorem 3.5.4])

\[
(2.11) \quad F(z) = \int_{-\infty}^{\infty} \frac{d\beta(t)}{1 - tz} = \frac{1}{1 - B_1 z} + \frac{B_2 z}{1 - B_1 z} - \cdots .
\]

It is now a consequence of the hypotheses on \( \beta(x) \) that \( F(z) \) is transcendental and meromorphic. Hence the theorem of Stieltjes mentioned prior to the statement of Theorem 1 yields \( B_n > 0, n = 1, 2, \cdots \) and \( \lim B_n = 0 \). Thus,

**Corollary 2.** A nondecreasing, symmetric distribution function, normalized by (2.9) having discrete, bounded spectrum with \( x = 0 \) the only limit point, determines a transcendental meromorphic function with an expansion of the form (2.11), where \( \{B_n\} \) is a positive null-sequence.

It is useful to have these two corollaries and Theorem 1 restated in somewhat different form.

**Corollary 3.** The denominators of the successive convergents of any continued fraction of the form (2.11) with \( B_n > 0 \) \((n > 0)\) and \( \lim B_n = 0 \) form a sequence of real orthogonal polynomials with the discrete domain of orthogonality described in Corollary 1.

Our proof of Theorem 3 (below) requires a Mittag-Leffler expansion of \( G'(z) \). To this end we call attention to the following theorem of Montel (Obrechkoff [8; Theorem XXI]):

If a sequence of rational functions converges uniformly to a meromorphic function and if the zeros and poles of each rational function are simple, real, and alternate, then the meromorphic function has the expansion

\[
B - Az + \sum_{n=1}^{\infty} A_n \left( \frac{1}{z - \alpha_n} + \frac{1}{\alpha_n} \right)
\]

where \( \sum A_n/\alpha_n^\nu \) converges and \( A, B, A_1, A_2, \ldots, A_n, \cdots \) have the same sign and the \( \alpha_n \) are real and distinct.
The hypotheses of this theorem are satisfied by the rational functions \( \phi^{PQIz}_1(1/z) / \phi^{(s)}(1/z) \) because of Lemma 1 and Theorem 1. Furthermore, \( G^{(s)}(z) \) is even. Hence, after simplification,

\[
G^{(s)}(z) = -A^{(s)} + \sum_{n=1}^{\infty} \frac{2A_n^{(s)}}{z^2 - (\alpha_n^{(s)})^2}.
\]

Finally, \( G^{(s)}(0) = 1 \) so that \( A^{(s)} \leq 0 \) and \( A_n^{(s)} < 0 \) \((n > 0)\). In this representation, and in all similar expansions, we agree to order the poles, \( 0 < \alpha_1^{(s)} < \alpha_2^{(s)} < \cdots, \alpha_n \to \infty \).

**Theorem 2.** The transcendental meromorphic function of Theorem 1 has the expansion

\[
G^{(s)}(z) = -A^{(s)} + \sum_{n=1}^{\infty} \frac{2A_n^{(s)}}{z^2 - (\alpha_n^{(s)})^2},
\]

where \(-\Sigma A_n^{(s)}(\alpha_n^{(s)})^{-2} < \infty, A^{(s)} \leq 0 \) and \( A_n^{(s)} < 0, n = 1, 2, \cdots \). The convergence is uniform in compact sets which exclude the poles of \( G^{(s)}(z) \).

3. The construction of the distribution function. With the preliminaries now settled, we can proceed with a consideration of the first of our goals; namely, the construction which explicitly exhibits the relationship between \( G^{(s)}(1/x) \) and \( \{\phi_n^{(s)}(x)\} \). We state this result as Theorem 3, a generalization and correction of the corresponding theorem in [6, Theorem 5]. The approach in this section owes its inspiration to the ideas expressed in [6].

Set \( z = 1/x \) in (2.1), (2.2) and (2.5). Define \( F_n^{(s)}(z) = z^n \phi_n^{(s)}((1/z)) \). Then,

\[
(3.1) \quad F_{n+1}^{(s)}(z) = F_n^{(s)}(z) - a_{n+1} z^2 F_{n-1}^{(s)}(z) \quad (n \geq 1)
\]

with

\[
(3.2) \quad F_0^{(s)}(z) = 1, \quad F_1^{(s)}(z) = 1
\]

and

\[
(3.3) \quad F_n^{(s)}(z) = F_{n-1}^{(s+1)}(z) - b_{n+1} z^2 F_{n-2}^{(s+2)}(z) \quad (n \geq 2).
\]

Furthermore,

\[
\frac{\phi_n^{(s)}(1/z)}{z \phi_n^{(s)}(1/z)} = \frac{F_{n-1}^{(s+1)}(z)}{F_n^{(s)}(z)} \quad (n \geq 1).
\]

Now divide (3.3) by \( F_{n-1}^{(s+1)}(z) \) and let \( n \to \infty \). This yields
which may be interpreted as an alternate expression for (2.7). We combine (3.3) and (3.4) to obtain
\begin{align*}
F_n^{(s)}(z) - F_{n-1}^{(s+1)}(z) &= b_{n+2}z^2G^{(s+1)}(z)(F_n^{(s+1)}G^{(s+1)}(z) - F_{n-2}^{(s+1)}) \\
&= b_{n+2}z^2G^{(s+1)}G^{(s+1)}(n+1)
\end{align*}
for \( n \geq 1 \). (Here and in the next equation \( F_n^{(s)} = F_n^{(s)}(z), G^{(s)} = G^{(s)}(z), \) etc.). Such an expression suggests iteration. With the aid of (3.4) written as
\begin{align*}
F_1^{(s+n-1)}G^{(s+n-1)}(z) - F_0^{(s+n)}(z) = G^{(s+n-1)}(z) - 1 \\
&= b_{n+1}z^2G^{(s+n)}(z)G^{(s+n)}(n+1)
\end{align*}
and after some simplification, including multiplying through by \( z^{-n-p-1} \), we compute
\begin{align*}
\sum_{n=1}^{\infty} z^{-n-p-1}G^{(s)}(z)F_n^{(s)}(z) - z^{-n-p-1}F_n^{(s+1)}(z)
&= z^{-n-p-1} \prod_{k=1}^{n} b_{k+s}G^{(k+s)}(z)G^{(s)}(z)
\end{align*}
for any \( p \) and all \( n \geq 1 \). Now choose \( C' \) a circle small enough to exclude all the singularities of \( G^{(s)}(z), G^{(s+1)}(z), \cdots, G^{(s+n)}(z) \). Such a circle exists because \( G^{(m)}(0) = 1 \) for all \( m \). The degree of \( F_k^{(s)}(z) \) is \( 2[k/2] \). Hence the residues at the origin of each term in (3.5) is readily computed and we have
\begin{align*}
\frac{1}{2\pi i} \int_C z^{-n-p-1}F_n^{(s)}(z)G^{(s)}(z)dz = \delta_{n,p} \prod_{k=1}^{n} b_{k+s}
\end{align*}
for \( 0 \leq p \leq n \) and \( n = 1, 2, 3, \cdots \). If we define the empty product as unity, then (3.6) holds for \( n = 0 \) also. The change of variables, \( z = 1/x \), casts (3.6) into
\begin{align*}
\frac{1}{2\pi i} \int_C x^p \phi_n^{(s)}(x)\{x^{-1}G^{(s)}(1/x)\}dx = \delta_{n,p} \prod_{k=1}^{n} b_{k+s}
\end{align*}
for \( 0 \leq p \leq n \) and \( n \geq 0 \). Here \( C \) is the circle reciprocal to \( C' \). \( C \) surrounds all of the singularities of \( G^{(k+s)}(1/x), k = 0, 1, \cdots, n \). The integration is taken in the positive direction. We may convert (3.7) into a real orthogonality relationship by substituting the representation of \( G^{(s)}(z) \), given in Theorem 2, into (3.7) and interchanging the order of integration and summation. With the observation that the residue of \( x^{-1}G^{(s)}(1/x) \) at \( x = \pm 1/\alpha_n^{(s)} \) is \(-A_n^{(s)}(\alpha_n^{(s)})^{-2} > 0 \), we have
\begin{align*}
-A^{(s)} \delta_{n,p} \phi_n^{(s)}(0) + \sum_{n=1}^{\infty} x^p \phi_n^{(s)}(x) \text{Res} \{x^{-1}G^{(s)}(1/x)\} = \delta_{n,p} \prod_{k=1}^{n} b_{k+s}
\end{align*}
for $0 \leq p \leq n, n = 0, 1, 2, \ldots$. The summation is extended over all the poles of $x^{-G^{(e)}(1/x)}$. We express this and the results of section two as

**Theorem 3.** Let $\{b_n\}$ be an arbitrary sequence of positive constants with $\lim b_n = 0$. Suppose $\{\phi_n^{(e)}\}$ are the sets of orthogonal polynomials determined by (2.1) and (2.2). Suppose $G^{(e)}(z)$ is defined by (2.7) and $\beta^{(e)}(x)$ is the unique normalized distribution function associated with $\{\phi_n^{(e)}(x)\}$. Then for each nonnegative integer $s$,

(i) the spectrum of $\beta^{(e)}(x)$ is the closure of the set of poles of $G^{(e)}(1/z)$; namely, $x = 0$ and $x = \pm 1/\alpha_n^{(e)}, n = 1, 2, \ldots$.

(ii) the jump of $\beta^{(e)}(x)$ at these poles is equal to the residue of $x^{-G^{(e)}(1/x)}$ there. That is,

$$\beta^{(e)}(x + 0) - \beta^{(e)}(x - 0) = -A_n^{(e)}(\alpha_n^{(e)})^{-2}$$

for $x = \pm 1/\alpha_n^{(e)}$.

(iii) $\beta^{(e)}(+0) - \beta^{(e)}(-0) = -A^{(e)}$.

(iv) For each $p, 0 \leq p \leq n$ and all $n = 0, 1, 2, \ldots$,

$$\int_{-a}^{a} x^p \phi_n^{(e)}(x) d\beta^{(e)} = \int_{-a}^{a} \phi_n^{(e)}(x) \phi_n^{(e)}(x) d\beta^{(e)} = \delta_n p \prod_{k=1}^{n} b_{k+1},$$

where $[-a, a]$ is an interval large enough to include the bounded set, $\{\pm 1/\alpha_n^{(e)}\}$.

The criterion $\Sigma b_n < \infty$ is both necessary and sufficient to imply the existence of $\lim_n x^n \phi_n^{(e)}(1/x)$.

**Corollary 4.** If $\Sigma b_n < \infty$ then (uniformly)

$$\lim_{n \to \infty} \frac{\phi_n^{(e+1)}(1/x)}{x \phi_n^{(e)}(1/x)} = \frac{\lim_{n \to \infty} x^{n-1} \phi_n^{(e+1)}(1/x)}{\lim_{n \to \infty} x^n \phi_n^{(e)}(1/x)} = \frac{E^{(e+1)}(x)}{E^{(e)}(x)} = G^{(e)}(x).$$

Here, $E^{(e+1)}(x)$ and $E^{(e)}(x)$ are entire functions. Conversely, if $\lim_n x^n \phi_n^{(e)}(1/x)$ converges uniformly in a bounded closed domain about $x = 0$ then $\Sigma b_n < \infty$.

**Proof.** The sufficiency, with the modification at $x = 0$ previously mentioned, is the main theorem of Dickinson, Pollak and Wannier. Their proof depends only upon $\Sigma b_n < \infty$ and hence is applicable here. The necessity is proved by an appeal to a theorem of Polya (Obrechkoff, [8, Theorem IV] which states in effect that the limit of a uniformly
converging sequence of polynomials with real, symmetric zeros is an entire function. Therefore, the coefficient of $x^2$ in $x^n\phi_n^{(s)}(1/x)$ converges to the coefficient of $x^2$ in the series expansion of the limit function. But, we see that $x^n\phi_n^{(s)}(1/x) = 1 - (b_{1+s} + b_{2+s} + \cdots + b_{n+s})x^2 + O(x^r)$ for $n = 1, 2, \cdots$. This proves the necessity. More interestingly;

**Theorem 4.** A necessary and sufficient condition that $\lim x^n\phi_n^{(s)}(1/x)$ converges uniformly in some bounded, closed domain containing $x=0$ (and hence converges to an entire function) is that $\Sigma a_{n}^{-2} < \infty$.

**Proof.** Assume that $\lim x^n\phi_n^{(s)}(1/x)$ converges uniformly. But the aforementioned theorem of Polya we know the limit function is entire. Denote its zeros by $\pm \alpha_i^{(s)}$, $0 < \alpha_1^{(s)} < \alpha_2^{(s)} < \cdots$. Let $\pm \alpha_k^{(s)}$, $k = 1, 2, \cdots \lfloor n/2 \rfloor$ be the $2\lfloor n/2 \rfloor$ zeros of $x^n\phi_n^{(s)}(1/x)$ ordered

$$0 < \alpha_{1,n}^- < \alpha_{2,n}^- < \cdots < \alpha_{[n/2],n}^-.$$

Now a theorem of Hurwitz asserts that $\lim_{n} \alpha_k^{(s)} = \alpha_k^{(s)}$, $k = 1, 2, \cdots$. Referring once again to Polya’s Theorem we conclude that $\Sigma (\alpha_k^{(s)})^{-2}$ converges. Of course, the zeros $\pm \alpha_k^{(s)}$ are the poles of $G^{(s)}(1/x)$. From (3.4) they are also the zeros of $G^{(s-1)}(1/x)$. But the zeros and poles of $G^{(s-1)}(1/x)$ (for any $s$) alternate on the real axis. Hence $\Sigma (\alpha_k^{(s-1)})^{-2}$ also converges. Successive applications of this reasoning yields the convergence of $\Sigma (\alpha_k^{(0)})^{-2} = \Sigma \alpha_k^{-2}$ after $s$ steps. We prove the sufficiency by showing that the convergence of $\Sigma \alpha_k^{-2}$ implies the convergence of $\Sigma b_n$.

Towards this end we note that the zeros of $\phi_n^{(s)}(x)$ and $\phi_n^{(s-1)}(x)$ are interlaced (Lemma 1). In our notation, the reciprocals of these zeros are ordered as follows;

$$< \alpha_{1,n+1}^- < \alpha_{1,n}^- < \alpha_{2,n+1}^- < \alpha_{2,n}^- < \cdots,$$

for $n = 1, 2, \cdots$. Hence,

$$\frac{1}{\alpha_{1,n}^{-2}} < \frac{1}{\alpha_{1,n+1}^{-2}} < \frac{1}{\alpha_{1,n+2}^{-2}} < \cdots$$

(3.9)

$$\frac{1}{\alpha_{2,n}^{-2}} < \frac{1}{\alpha_{2,n+1}^{-2}} < \frac{1}{\alpha_{2,n+2}^{-2}} < \cdots$$

$$\cdots$$

$$\frac{1}{\alpha_{[n/2],n}^{-2}}.$$
But $b_1 + b_2 + \cdots + b_n = \sum_{k=1}^{n} \alpha_k^2$, since the coefficient of $x^2$ in $x^n \phi_n'(1/x)$ is the sum of the squares of the zeros of $\phi_n'(x)$. Corollary 4 completes the proof.

For a special case, Dickinson [4] has computed the moments, $\{m_n^{(s)}\}$, of $\beta^{(s)}$ in terms of the parameters of $G^{(s)}(z)$. We know in advance that the odd moments are zero (Shohat [11, Theorem II]) and that the moments are the coefficients in the Taylor series expansion of $G^{(s)}(z)$ about $z = 0$. Specifically,

Corollary 5. Under the hypothesis of Theorem 3;

\begin{align*}
m_{n}^{(s)} &= 0, \quad n \text{ odd}, \\
m_{n}^{(s)} &= -A^{(s)} - 2 \sum_{k=1}^{n} A_k^{(s)} (\alpha_k^{(s)})^{-2} = 1, \\
m_{n}^{(s)} &= -2 \sum_{k=0}^{n} A_k^{(s)} (\alpha_k^{(s)})^{-n-2}, \quad n > 0 \text{ and even}.
\end{align*}

Proof. We have from Theorem 2 that

\begin{align*}
G^{(s)}(z) &= -A^{(s)} + \sum_{n=1}^{\infty} \frac{2A_n^{(s)}}{z^2 - (\alpha_n^{(s)})^2} \\
&= -A^{(s)} - 2 \sum_{n=1}^{\infty} A_n^{(s)} (\alpha_n^{(s)})^{-2} \{1 - z^2/(\alpha_n^{(s)})^2\}^{-1} \\
&= -A^{(s)} - \sum_{k=0}^{\infty} \frac{z^{2k}}{k!} \sum_{n=1}^{\infty} 2A_n^{(s)} (\alpha_n^{(s)})^{-2k-2}
\end{align*}

for $|z| < |\alpha_n^{(s)}|$. Thus

\begin{equation}
(3.10) \quad x^{-i}G^{(s)}(1/x) = -A^{(s)}/x - \sum_{k=0}^{\infty} x^{-2k-1} \sum_{n=1}^{\infty} 2A_n^{(s)} (\alpha_n^{(s)})^{-2k-2}.
\end{equation}

But then

\[ \frac{1}{2\pi i} \int_{\gamma} x^n [x^{-i}G^{(s)}(1/x)] dx = \int_{-\gamma} x^n d\beta^{(s)} \]

and the Corollary is proved.

4. A representation theorem for the meromorphic function $G^{(s)}(z)$. In previous sections we have concentrated on the determination of the spectrum of $\beta^{(s)}$ from a knowledge of $\{b_n\}$. In this and the succeeding section we direct our attention to the class of meromorphic functions which determine real orthogonal polynomials with distributions having spectra of the type described in Corollary 1. We denote the class of such meromorphic functions by PIF; a notation motivated by the notation for a related class of functions. We express our main theorem by the following:
Theorem 5. The following four statements are equivalent*:

1. \[ zF(z) \in \text{PIF} \]
2. \[ F(z) = \frac{1}{1 - B_n 2^z - B_n 2^{z^2}} \ldots , \]

with \( B_n > 0 \) \( n = 1, 2, \ldots \), and \( \lim B_n = 0 \).

3. \[ F(z) = -A + \sum_{n=1}^{\infty} \frac{2A_n}{z^2 - \alpha_n^2} , \]
where \( A \leq 0, A_n < 0, n = 1, 2, 3, \ldots, -A - \sum 2A_n \alpha_n^2 = 1, 0 < \alpha_1 < \alpha_2 < \cdots, \alpha_n \to \infty \).

4. \[ F(z) = \prod_{n=1}^{\infty} \frac{1 - \gamma_n^{z^2}/\gamma_n^2}{1 - \gamma_n^2/\alpha_n^2} , \]
where \( 0 < \alpha_1 < \gamma_1 < \alpha_2 < \gamma_2 < \cdots, \alpha_n \to \infty \) and \( \prod_{n=1}^{\infty} (1 + \gamma_n^{-2})(1 + \alpha_n^{-2})^{-1} \) converges (and is therefore \( \neq 0 \)).

Proof. (1)\( \Rightarrow \)(2) is established in §2 along with (2)\( \Rightarrow \)(3) (Theorem 2). We shall prove (3)\( \Rightarrow \)(2) and then (3)\( \Leftrightarrow \)(4) to complete the proof.

(a) We prove (3)\( \Rightarrow \)(2). Suppose \( F \) is defined by (3). Then \(-A - \sum 2A_n \alpha_n^{-2} = 1\) establishes the uniform convergence of the right-hand side of (3). Hence \( F \) is transcendentally meromorphic and analytic at \( z = 0 \). The Taylor series (in \( z^2 \)) for \( F \) at \( z = 0 \) has only positive coefficients. From the theory of continued fractions (Shohat [11, pg. 455]), we deduce a representation for \( F \) in the form (2) with the stated conditions on \( \{B_n\} \).

(b) To prove the equivalence of (3) and (4) we set \( z = it \) and define \( f(t) = tF(it) \). Then \( f(t) \) is a meromorphic function which maps the right half-plane into itself, the imaginary axis into itself and the reals into the reals. These properties of \( f(t) \) follow, if we assume \( F \) is given by (3), by taking real and imaginary parts of (3). Richards [9] made a detailed study of such functions which he named \( i\text{PRF} \) (\( P \) for positive real part; \( PI \) for positive imaginary part in our case). The transformation, \( t = -iz \) and the definition \( F(z) = if(-iz)/z \), therefore, converts Richards' theorems into results for \( F(z) \). In particular then, (3)\( \Rightarrow \)(4) as a consequence of [9; Theorem 12] and because \( f'(0) = F'(0) = 1 \). Conversely, if \( F \) is given by (4) then \( f(t) \in i\text{PRF} \) by [9, Corollary 12.1] and (4)\( \Rightarrow \)(3) by [9; Corollary 10.1]. This completes the proof.

5. The constants \( A^{[s]} \). The mass assigned by the weight function

* We suspend our convention on superscripts for this section.
to each point of the orthogonality domain may be determined, as we have seen, by examination of the residue at each pole of a function meromorphic in $1/x$ with the single exception of the mass at zero, $-A^{(s)}$. If the mass at zero is zero for each $s$, as it is in the examples considered by Dickinson, Pollak and Wannier [6] and Carlitz [2], the exception is vacuous. It is of some interest then, to consider the problem of characterizing in function-theoretic terms those PIF functions with $A^{(s)} = 0$, $s = 0, 1, 2, \cdots$. In the course of this section we derive some theorems, parts of which yield conditions assuring nonzero mass at $x = 0$. We begin by proving a Lemma fundamental to this part of our study.

**Lemma 2.** In the Stolz domain,

$$0 < \theta_1 \leq \arg z \leq \theta_2 < \pi, \quad \text{and for each } s \geq 0,$$

$$\lim_{|z| \to \infty} G^{(s)}(z) = -A^{(s)}.$$

**Proof.** This is a well-known theorem in a different guise. For, [9, Theorem 5 and Corollary 10.1] shows that $\lim_{|t| \to \infty} f(t)/t$ exists ($t$ in the domain $|\arg t| \leq \theta < \pi/2$) and is nonnegative. Now $G^{(s)}(z)$ is PIF from Theorem 5 (2), so that $f(t) = tG^{(s)}(it) \in IPR$ and the Lemma follows from [9; Corollary 10.1]. A second Lemma follows from (3.4) and Lemma 2.

**Lemma 3.** Either the terms of $\{A^{(s)}\}_{s=1}^{\infty}$ are all zero or they are alternately zero and nonzero.

**Proof.** Set $z = iy$, ($y$ real) in (3.4) and write

$$\frac{1}{G^{(s)}(iy)} = 1 + b_{i+s}y^sG^{(s+1)}(iy).$$

Then one iteration of (5.2) yields

$$\frac{1}{G^{(s)}(iy)} = 1 + b_{i+s}(1/y^2 + b_{i+s}G^{(s+2)}(iy)^{-1}).$$

Now let $y \to \infty$ in (5.2) and (5.3) and evoke Lemma 2. Equation (5.2) shows that $A^{(s)}A^{(s+1)} \neq 0$ is impossible and (5.3) shows that either $A^{(s)} = A^{(s+2)} = 0$ or $A^{(s)}A^{(s+2)} \neq 0$ for every $s$. But this is just an alternate way of expressing the content of Lemma 3.

**Theorem 6.** For all $s = 0, 1, 2, \cdots$

$$-A^{(s)} = \lim_{n \to \infty} \prod_{k=1}^{n} (\alpha_k^{(s)}/\alpha_k^{(s+2)})^3 < \infty.$$
Proof. Set $z = (iy)^{-1}$ in Theorem 5 and note that

$$\lim_{z \to -\infty} G^{(s)}(z) = -A^{(s)} = \lim_{y \to 0} \prod_{n=1}^{\infty} \left[ \frac{y^2 + (\alpha_n^{(s+1)})^{-2}}{y^2 + (\alpha_n^{(s)})^{-2}} \right].$$

Since

$$\frac{(\alpha_n^{(s)})^{-2} - (\alpha_n^{(s+1)})^{-2}}{y^2 + (\alpha_n^{(s)})^{-2}} < 1 - \left( \frac{\alpha_n^{(s)}}{\alpha_n^{(s+1)}} \right)^2$$

for all $y$ and every $n$, the hypothesis that $\prod (\alpha_n^{(s)}/\alpha_n^{(s+1)})^2$ converges implies the uniform convergence of the rightmost factor in (5.5) in every set $y^2 \leq R^2$ and thus the continuity of $G^{(s)}(1/iy)$ at $y = 0$. This proves (5.4) when the product converges. Now $|\alpha_n^{(s)}| < |\alpha_n^{(s+1)}|$ so that divergence of $\prod (\alpha_n^{(s)}/\alpha_n^{(s+1)})^2$ is divergence to zero. Hence, given any $\epsilon > 0$ there exists an $N$ such that for all $n > N$

$$\prod_{n=1}^{N} (\alpha_n^{(s)}/\alpha_n^{(s+1)})^2 < \epsilon.$$ 

But

$$\prod_{n=1}^{N} \left[ \frac{y^2 + (\alpha_n^{(s+1)})^{-2}}{y^2 + (\alpha_n^{(s)})^{-2}} \right] \leq \prod_{n=1}^{N} \left[ \frac{y^2 + (\alpha_n^{(s+1)})^{-2}}{y^2 + (\alpha_n^{(s)})^{-2}} \right]$$

$$\leq \prod_{n=1}^{N} \left[ \frac{y^2 + (\alpha_n^{(s+1)})^{-2}}{(\alpha_n^{(s)})^{-2}} \right] \leq \left( 1 + \frac{1}{N} \right)^N \prod_{n=1}^{N} (\alpha_n^{(s)}/\alpha_n^{(s+1)})^2.$$

The leftmost inequality holds for every $N$ because each term in the product is less than one for every $y$. The last inequality holds for all $y$ satisfying $y \leq (\sqrt{N} \alpha_n^{(s+1)})^{-1}$, $n = 0, 1, \cdots, N$. Because of the ordering of the poles of $G^{(s)}(z)$, this can be accomplished by the restriction $y \leq (\sqrt{N} \alpha_n^{(s+1)})^{-1}$. Hence the limit on the right side of (5.5) must be zero, proving Theorem 6 if the product diverges. A less complete result follows from (2.13).

**Theorem 7.** If $A^{(s+1)} = 0$ then a necessary and sufficient condition for $A^{(s)} \neq 0$ is that $\Sigma A_n^{(s+1)}$ converge. In either case

$$A^{(s)} = -(1 - b_{t+2} \Sigma 2A_n^{(s+1)})^{-1}$$

(suitably interpreted if $\Sigma A_n^{(s)}$ diverges).

**Proof.** Set $z = (iy)^{-1}$ ($y$ real) in the representation for $G^{(s+1)}$ given by (2.13). Since $A^{(s+1)} = 0$ and $0 < \alpha_1^{(s+1)} < \alpha_2^{(s+1)} < \cdots$, we have for all $y \leq (\alpha_1^{(s+1)})^2$,

$$(-1/2) \sum_{n=1}^{N} A_n^{(s+1)} \leq \frac{-A_1^{(s+1)}}{1 + (\alpha_1^{(s+1)})^{-2}y^2} \leq \sum_{n=1}^{N} \frac{-A_n^{(s+1)}}{1 + (\alpha_n^{(s+1)})^{-2}y^2}.$$
But from (3.4), with \( z = (iy)^{-1} \),

\[
y^{-2}G^{(s+1)}(-i/y) = \frac{1}{\Gamma(s)} - 1.
\]

Let \( y \to 0 \) and assume \( \sum A_{n}^{(s+1)} \) diverges. Then

\[
\lim_{y \to 0} G^{(s)}(-i/y) = -A^{(s)} = 0.
\]

Now suppose \( \sum A_{n}^{(s+1)} \) converges. Since

\[
y^{-2}G^{(s+1)}(-i/y) = \sum_{n=1}^{\infty} \frac{-A_{n}^{(s+1)}}{1 + (\alpha_{n}^{(s+1)})^{-2}y^2} \leq \sum_{n=1}^{\infty} A_{n}^{(s+1)},
\]

we conclude that \( \sum A_{n}^{(s+1)}[1 + (\alpha_{n}^{(s+1)})^{-2}y^2]^{-1} \) converges uniformly for all \( y \) in, say \( y_0 \leq R \), and hence represents a continuous function at \( y = 0 \). Therefore, from (5.6) and (5.7).

\[
b_{1+s}^{-1}(-1/A^{(s)} - 1) = -\sum_{n=1}^{\infty} A_{n}^{(s+1)}.
\]

This completes the proof.

Hence if \( \{A^{(s)}\} \) is a sequence of zeros, \( \sum A_{n}^{(s)} \) must diverge for each \( s \). Conversely, if all such series diverge \( \{A^{(s)}\} \) is a sequence of zeros. Is it possible for \( \sum A_{n}^{(s)} \) to converge and \( A^{(s)} \neq 0 \)? \( A^{(s)} = 0 \)? In other words, if \( \{A^{(s)}\} \) is alternately zero and nonzero, what can be said about the convergence of \( \sum A_{n}, \sum A_{n}^{(1)}, \sum A_{n}^{(2)}, \ldots \), besides the statement that they all cannot diverge? We leave this question open.

Finally,

**Theorem 8.** The constants \( \{b_{n+s}\} \) and \( A^{(s)} \) are related by

\[
\frac{-1}{A^{(s)}} = 1 + \frac{b_{1+s}}{b_{2+s}} + \frac{b_{1+s}b_{2+s}}{b_{3+s}} + \frac{b_{1+s}b_{2+s}b_{3+s}}{b_{4+s}} + \frac{b_{1+s}b_{2+s}b_{3+s}b_{4+s}}{b_{5+s}} + \cdots,
\]

so that \( A^{(s)} = 0 \) if and only if the series (5.8) diverges.

This theorem is known (see [3; Theorem 2] and the references therein). We include the statement here for completeness.

6. An example. Wall [15] studied a certain continued fraction which arose in a number-theoretic context. By suitable changes of variable this example may be used to illustrate the theorems of the
previous sections. There seem to be relatively few cases of interesting special functions for which the sequences \( \{b_n\} \) and \( \{A^{(s)}\} \) are known explicitly and \( \{A^{(s)}\} \) is not all zeros. The author was able to find only this one example. Choose \( 0 < r < 1 \) and \( 0 < q < 1 \) and define \( b_0 = r \),

\[
(6.1) \quad b_{2k+2} = (1 - rq^k)q^{k+1}, \quad b_{2k+3} = rq^{k+1}(1 - q^{k+1})
\]

\( k = 0, 1, 2, \cdots \);

\[
(6.2) \quad M_1 = r \prod_{k=1}^{\infty} (1 - rq^k);
\]

\[
(6.3) \quad M_k = \frac{r^{k-1}M_1}{(1 - q)(1 - q^2) \cdots (1 - q^{k-1})}, \quad k \geq 2.
\]

Then Wall [15] has shown, in our notation,

\[
(6.4) \quad \frac{1}{G^{(0)}(z)} = 1 + z^2 \sum_{k=1}^{\infty} \frac{M_k q^{-k}}{z^k - q^{-k}}.
\]

From (3.4) and (6.4) we deduce that

\[
(6.5) \quad G^{(1)}(z) = \sum_{k=1}^{\infty} \frac{-M_k (rq^k)^{-1}}{z^k - q^{-k}}
\]

so that \( A^{(1)} = 0, -2A^{(1)}_k = M_k (rq^k)^{-1} \) and \( \alpha^{(1)}_k = q^{-k} \). We use Theorem 7 with \( s = 0 \) to deduce that \( A^{(0)} \neq 0 \) if \( \sum M_k (rq^k)^{-1} \) converges. The ratio test yields the convergence of this series if \( r < q \) and its divergence if \( q < r \). Thus the terms in \( \{A^{(s)}\} \) are all zero if \( q < r \) and are alternately zero and nonzero, \( A^{(0)} \neq 0 \), if \( r < q \). Wall has also shown that

\[
(6.6) \quad G^{(1)}(z) = \sum_{n=0}^{\infty} \left[ q^n \prod_{k=0}^{n-1} (1 - rq^k) \right] z^n.
\]

Hence, the moments \( m^{(1)}_{2n} \) can be read off immediately (see Corollary 5)

\[
(6.7) \quad m^{(1)}_{2n} = q^n \prod_{k=0}^{n-1} (1 - rq^k), \quad (n \geq 0)
\]

where the empty product is defined as unity. Incidentally, \( \sum b_k < \infty \) for all choices of \( r \) and \( q \) so that this example is one that is included in the Dickinson, Pollak and Wannier theory.

7. Acknowledgement. A special note of thanks is due Professor J.L. Ullman for the many hours of valuable discussions on the material of this note. His encouragement, interest and stimulation were a major source of inspiration.
