TWO NOTES ON REgressive ISOLs

Joseph Barback
This paper deals with regressive functions and regressive isols. It was proven by J. C. E. Dekker in [2] that the collection $A_B$ of all regressive isols is not closed under addition. In the first note of this paper we shall give another proof of this fact by considering a new relation, denoted by $\succ$, between infinite regressive isols. Let $A$ and $B$ denote infinite regressive isols. The main results established in the first note are:

(1) $A \preceq B \rightarrow A \succ B$, yet not conversely.

(2) $A + B \in A_B \rightarrow A \prec B$, yet not conversely.

(3) There exist infinite regressive isols which are not $\prec$ related.

(4) $A_B$ is not closed under addition.

In addition, the following result is stated.

(5) $A + B \in A_B \rightarrow \min(A, B) \preceq A + B$, yet not conversely.

In the second note we consider the $\preceq^*$ relation between regressive isols. A natural question concerning this relation is whether $A \preceq^* B$, where $A$ and $B$ are regressive isols, is a necessary or a sufficient condition for the sum $A + B$ to be regressive. In the second note we show that this condition is neither necessary nor sufficient.

We shall assume that the reader is familiar with the notations, terminology and main results of [1] and [2].

Preliminaries. Let $\varepsilon = \{0, 1, 2, 3, \ldots\}$ be the set of nonnegative integers (numbers). A one-to-one function $t_n$ from $\varepsilon$ into $\varepsilon$ is regressive if there is a partial recursive function $p(x)$ such that $pt_\varepsilon \in \delta p$ and $p(t_0) = t_0$, $(\forall n)[p(t_{n+1}) = t_n]$. The function $p$ is a regressing function of $t_n$ if $p$ has the following additional properties: $\delta p \subseteq \delta p$ and $(\forall x)[x \in \delta p \rightarrow (\exists n)[p^*_n(x) = p(x)]]$. It is known (cf. [1]) that every regressive function has a regressing function. A set is regressive if it is finite or the range of a regressive function. A set is retraceable if it is finite or the range of a strictly increasing regressive function. Let $p$ be a regressing function of $t_n$, then the function $p^*$ is defined by: $\delta p^* = \delta p$ and $p^*(x) = (\mu n)[p^*_n(x) = p^*_n(x)]$. It follows that $p^*$ is a partial recursive function and $(\forall n)[p^*(t_n) = n]$.

Let $s_n$ and $t_n$ be two one-to-one functions from $\varepsilon$ into $\varepsilon$. Then $s_n \preceq^* t_n$, if there is a partial recursive function $f$ such that

(1) $\rho s \subseteq \delta f$ and $(\forall n)[f(s_n) = t_n]$.

Also, $s_n$ and $t_n$ are said to be recursively equivalent (denoted $s_n \simeq t_n$)
if there is a one-to-one partial recursive function $f$ such that (1) holds. Let $\sigma$ and $\tau$ be two sets. Then $\sigma \leq^* \tau$, if either $\sigma$ is finite and card. $\sigma \leq \text{card.} \tau$, or $\sigma$ is infinite and there is a partial recursive function $f$ such that $\sigma \subseteq \delta f$, $f$ is one-to-one on $\sigma$ and $f(\sigma) = \tau$. Let $S$ and $T$ be two isols. Then $S \leq^* T$, if there are sets $\sigma \in S$ and $\tau \in T$ such that $\sigma \leq^* \tau$. The following propositions will be useful:

(a) Retraceable sets are either recursive or immune.

(b) Every function recursively equivalent to a regressive function is regressive.

(c) Every set recursively equivalent to a regressive set is regressive.

(d) Let $\sigma = p_\sigma^n$ and $\tau = p_\tau^n$ where $s_n$ and $t_n$ are one-to-one regressive functions. Then $\sigma \leq^* \tau$ if and only if $s_n \leq^* t_n$, and $\sigma \simeq \tau$ if and only if $s_n \simeq t_n$.

(e) Let $s_n$ and $t_n$ be one-to-one functions from $\varepsilon$ into $\varepsilon$. Then $s_n \simeq t_n$ if and only if $s_n \leq^* t_n$ and $t_n \leq^* s_n$.

Proposition (a) is proven in [3]. Propositions (b) and (c), and the second part of (d) are proven [1]. Both (e) and the first part of (d) are given in [2].

Two sets $\alpha$ and $\beta$ are said to be separated (denoted $\alpha \mid \beta$) if there are disjoint r.e. sets $\alpha^\ast$ and $\beta^\ast$ such that $\alpha \subseteq \alpha^\ast$ and $\beta \subseteq \beta^\ast$. Two functions $a_n$ and $b_n$ are said to be separated (denoted $a_n \mid b_n$) if their ranges are separated sets. We will use the familiar primitive recursive functions $j$, $k$ and $l$ defined by

$$j(x, y) = x + (x + y)(x + y + 1)/2,$$

$$j(k(n), l(n)) = n.$$ 

The function $j$ maps $\varepsilon^2$ one-to-one onto $\varepsilon$.

**Note 1.** The $\Downarrow$ relation.

**DEFINITION 1.** Let $a_n$ and $b_n$ be any two one-to-one functions from $\varepsilon$ into $\varepsilon$. Then $a_n \Downarrow b_n$ if there is a partial recursive function $p(x)$ such that

$$(\forall n)[a_n \in \delta p \text{ and } p(a_n) = b_n] \lor (b_n \in \delta p \text{ and } p(b_n) = a_n).$$

The following proposition can be readily proven using the definitions of the concepts involved. Its proof will be omitted.

**PROPOSITION 1.1.** Let $a_n$ and $b_n$ be any two one-to-one functions from $\varepsilon$ into $\varepsilon$. Then

(a) $a_n \Downarrow b_n \longrightarrow b_n \Downarrow a_n$,

(b) $a_n \leq^* b_n \longrightarrow a_n \leq^* b_n$. 

DEFINITION 2. Let \( A \) and \( B \) be any two infinite regressive isols. Then \( A \triangleright B \) if there are regressive functions \( a_n \) and \( b_n \) such that

\[
\rho a_n \in A, \quad \rho b_n \in B, \quad a_n | b_n, \quad a'_n | b'_n.
\]

REMARK. In view of Proposition (d) and part (c) of Proposition 1.1, we see that if \( A \) and \( B \) are infinite regressive isols, then \( A \triangleright B \) means that \( a_n \triangleright b_n \) for every pair \( a_n \) and \( b_n \) of separated, regressive functions ranging over sets in \( A \) and \( B \) respectively.

THEOREM 1.1. Let \( A \) and \( B \) be infinite regressive isols. Then

\[
A \equiv B \quad \text{implies} \quad A \triangleright B.
\]

Proof. Let \( a_n \) and \( b_n \) be any two (one-to-one) regressive functions ranging over sets in \( A \) and \( B \) respectively and such that \( a_n \equiv b_n \). Set \( a'_n = 2a_n \) and \( b'_n = 2b_n + 1 \). Then \( a_n \simeq a'_n, \quad b_n \simeq b'_n \) and \( a_n | b_n \). Taking into account Propositions (b), (c) and (d) it follows that \( a'_n \) and \( b'_n \) are separated, regressive functions which range over sets in \( A \) and \( B \) respectively. In addition, \( a_n \equiv b_n \) implies \( a'_n \equiv b'_n \). By Proposition 1.1 (b) this means \( a'_n \triangleright b'_n \), and therefore \( A \triangleright B \).

THEOREM 1.2. For all infinite regressive isols \( A \) and \( B \),

\[
A + B \in \Lambda_B \quad \text{implies} \quad A \triangleright B.
\]

Proof. Let \( A \) and \( B \) denote two infinite regressive isols whose sum is also regressive. Let \( a_n \) and \( b_n \) be regressive functions with \( \alpha = \rho a_n \in A, \beta = \rho b_n \in B \) and \( \alpha \mid \beta \). Then \( \alpha + \beta \in A + B \) and \( \alpha + \beta \) is a regressive set. Let \( c_n \) be a regressive function ranging over the set \( \alpha + \beta \) and let \( p(x) \) be a regressing function of \( c_n \). Set

\[
\delta = \{ x \mid (x = a_n \text{ and } p^*(b_n) < p^*(a_n)) \lor (x = b_n \text{ and } p^*(a_n) < p^*(b_n)) \}.
\]

We note that \( \delta \equiv \alpha + \beta \) and that for each number \( n \), exactly one of the numbers \( a_n \) and \( b_n \) belongs to \( \delta \). Let the function \( f \) with domain \( \delta \) be defined by

\[
f(x) = \begin{cases} 
  b_n, & \text{if } x = a_n, \\
  a_n, & \text{if } x = b_n.
\end{cases}
\]

It is easily seen that if \( f \) has a partial recursive extension then \( a_n \triangleright b_n \).
Since \( a_n \) and \( b_n \) are separated functions this fact would also imply that \( A \succ B \). Hence to complete the proof it suffices to show that \( f \) has a partial recursive extension. For this purpose, assume that \( x \in \delta \). Since \( \alpha \) and \( \beta \) are separated sets we can determine whether \( x \in \alpha \) or \( x \in \beta \).

First suppose that \( x \in \alpha \). Taking into account that \( a_n \) and \( c_n \) are regressive functions, we can find the numbers \( u \) and \( v \) such that \( x = a_u = c_v \). The number \( a_u \) belongs to \( \delta \) and therefore

\[
\begin{align*}
K & = \{ p^r(x) \mid 1 \leq r \leq v \}.
\end{align*}
\]

The members of the set on the right side can be effectively obtained from \( x \), since \( p \) is a partial recursive function. In addition, using once again the separability of the sets \( \alpha \) and \( \beta \), and the regressiveness of the function \( b_n \), it follows that we can find the number \( b_u \). This gives the value of \( f(x) \). In a similar fashion one can determine the value of \( f(x) \) in the event \( x \in \beta \). From these remarks we can conclude that \( f \) will have a partial recursive extension. This completes the proof.

REMARK. We shall state without proof, two additional facts which can be established in the proof of Theorem 1.2. These are

\[
\begin{align*}
(a) & \quad \delta \in \min (A, B), \\
(b) & \quad \delta \mid (\alpha + \beta) - \delta.
\end{align*}
\]

Since \( \alpha + \beta \in A + B \), these facts imply that

\[
(\ast) \quad \min (A, B) \leq A + B.
\]

In the proof of Theorem 1.2, \( A \) and \( B \) were assumed to be infinite regressive isols. However, it is easily seen that the relation denoted by \( (\ast) \) is also true in the event either \( A \) or \( B \) is finite, for in this case \( \min (A, B) \) assumes one of the values \( (A, B) \). From these remarks one has the following

THEOREM. **For all regressive isols** \( A \) and \( B \),

\[
A + B \in A_n \quad \min (A, B) \leq A + B.
\]

The statement obtained by reversing the implication in the above theorem is false, for in the second note it is shown that there are two infinite regressive isols which are comparable relative to the \( \leq^* \) relation, hence their minimum assumes one of these two values, and yet whose sum is not regressive. According to Theorem 1.1, this also means that reversing the implication in Theorem 1.2 yields a false statement as well.

**Theorem 1.3.** There exist infinite regressive isols \( A \) and \( B \) which
are not $\sim$ related.

**Proof.** Let $\{p_i\}$ be an enumeration of partial recursive functions of one variable such that:

(a) every partial recursive function of one variable occurs at least once in $\{p_i\}$,

(b) $p_0(1) \neq 3$ and $p_0(3) \neq 1$.

We shall define two functions $a_n$ and $b_n$ such that the recursive equivalence types, $A = \text{Req } \rho a_n$ and $B = \text{Req } \rho b_n$ satisfy the conditions of the Theorem.

Put $a_0 = 1$ and $b_0 = 3$. We note that (b) implies

\[(1) \quad p_0(a_0) \neq b_0 \quad \text{and} \quad p_0(b_0) \neq a_0 .\]

Let $t \geq 1$ and suppose that $a_0, \ldots, a_{t-1}$ and $b_0, \ldots, b_{t-1}$ have already been defined. We define $a_t$ and $b_t$ by setting

\[a_t = j(a_{t-1}, u_t) \quad \text{and} \quad b_t = j(b_{t-1}, v_t) ,\]

where the numbers $u_t$ and $v_t$ will be defined in such a manner that

\[(2) \quad p_t(a_t) \neq b_t \quad \text{and} \quad p_t(b_t) \neq a_t .\]

**The definition of $u_t$ and $v_t$.** Set

\[\eta = \{u \mid j(a_{t-1}, u) \in \delta p_t\} ,\]

\[\zeta = \{v \mid j(b_{t-1}, v) \in \delta p_t\} .\]

We consider three cases:

**Case I.** $\eta' \neq \phi$. Let $u$ be the smallest number belonging to $\eta'$. Then $p_t j(a_{t-1}, u)$ is undefined.

**Subcase I.1.** There exists a number $v$ such that

\[p_t j(b_{t-1}, v) \neq j(a_{t-1}, u) .\]

Set

\[u_t = u ,\]

\[v_t = (\mu v)[p_t j(b_{t-1}, v) \neq j(a_{t-1}, u)] .\]

**Subcase I.2.** For all numbers $v$,

\[p_t j(b_{t-1}, v) = j(a_{t-1}, u) .\]

Consider the number $j(a_{t-1}, u + 1)$. Since $j$ maps $\varepsilon^2$ one-to-one onto $\varepsilon$, ...
it follows that \( j(a_{t-1}, u + 1) \neq j(a_{t-1}, u) \). Hence for all numbers \( v \),
\[
p_t j(b_{t-1}, v) \neq j(a_{t-1}, u + 1).
\]
Clearly there exist numbers \( v' \) such that \( j(b_{t-1}, v') \neq p_t j(a_{t-1}, u + 1) \).

Set
\[
u_t = u + 1,
\]
\[
v_t = (\mu v') [j(b_{t-1}, v') \neq p_t j(a_{t-1}, u + 1)].
\]

**Case II.** \( \zeta' \neq \phi \). Here we proceed in a fashion similar to Case I. The details are omitted.

**Case III.** \( \eta' = \zeta' = \phi \), i.e., \( \eta = \zeta = \varepsilon \), i.e.,
\[
(\forall u)[j(a_{t-1}, u) \in \delta] \text{ and } (\forall v)[j(b_{t-1}, v) \in \delta],
\]
where \( \delta = \delta p_t \). The numbers in the following four lists:

<table>
<thead>
<tr>
<th>LI</th>
<th>( j(a_{t-1}, 0) ), ( j(a_{t-1}, 1) ), ( \cdots )</th>
</tr>
</thead>
<tbody>
<tr>
<td>L2</td>
<td>( p_t j(b_{t-1}, 0) ), ( p_t j(b_{t-1}, 1) ), ( \cdots )</td>
</tr>
<tr>
<td>L3</td>
<td>( j(b_{t-1}, 0) ), ( j(b_{t-1}, 1) ), ( \cdots )</td>
</tr>
<tr>
<td>L4</td>
<td>( p_t j(a_{t-1}, 0) ), ( p_t j(a_{t-1}, 1) ), ( \cdots )</td>
</tr>
</tbody>
</table>

are therefore all defined. Since the function \( j(x, y) \) is one-to-one, all numbers in LI are distinct and all numbers in L3 are distinct.

**Subcase III.1.** LI contains a number which does not occur in L2. Set
\[
u_t = (\mu v)(\forall v)[j(a_{t-1}, u) \neq p_t j(b_{t-1}, v)].
\]
Since all of the numbers in L3 are distinct, it follows that
\[
(\exists v)[j(b_{t-1}, v) \neq p_t j(a_{t-1}, u_t)].
\]
Set
\[
v_t = (\mu v)[j(b_{t-1}, v) \neq p_t j(a_{t-1}, u_t)].
\]

**Subcase III.2.** Every number of LI occurs at least once in L2. Since LI contains infinitely many numbers this implies that L2 contains infinitely many numbers. Hence, not only
\[
(\forall u)(\exists v)[j(a_{t-1}, u) \neq p_t j(b_{t-1}, v)],
\]
but also
\[
(\forall u)(\exists \text{ infinitely many } v)[j(a_{t-1}, u) \neq p_t j(b_{t-1}, v)].
\]
This must be true in particular for \( u = 0 \). Thus there exists an infinite
sequence $v_0, v_1, v_2, \cdots$ of distinct numbers such that 

$$(\forall n)[j(a_{t-1}, 0) \neq p_t j(b_{t-1}, v_n)].$$

Let 

$$n^* = (\mu n)[j(b_{t-1}, v_n) \neq p_t j(a_{t-1}, 0)].$$

Define 

$$u_t = 0, \quad v_t = v_{n^*}.$$ 

This completes the definition of the numbers $u_t$ and $v_t$, and hence also of the functions $a_n$ and $b_n$. It is readily verified that the numbers $a_t$ and $b_t$ have been so defined as to satisfy (2), that is 

$$p_t(a_t) = b_t \quad \text{and} \quad p_t(b_t) = a_t.$$ 

Combining this fact with (1) gives 

$$(3) \quad (\forall n)[p_n(a_n) \neq b_n \quad \text{and} \quad p_n(b_n) \neq a_n].$$

Let 

$$\alpha = \rho a_n \quad \text{and} \quad \beta = \rho b_n.$$ 

We claim:

(a) $a_n$ and $b_n$ are strictly increasing regressive functions and $\alpha$ and $\beta$ are retraceable sets,

(b) $\alpha \not| \beta$,

(c) $a_n$ and $b_n$ are not $\prec$ related,

(d) $\alpha$ and $\beta$ are immune sets.

Re (a): It follows from the definition of the function $j(x, y)$ that $x < j(x, y)$ for $x > 0$. Moreover, we have 

$$a_0 > 0 \quad \text{and} \quad (\forall n)(\exists u)[a_{n+1} = j(a_n, u)],$$

$$b_0 > 0 \quad \text{and} \quad (\forall n)(\exists v)[b_{n+1} = j(b_n, v)].$$

Hence 

$$a_0 < a_1 < a_2 < \cdots \quad \text{and} \quad b_0 < b_1 < b_2 < \cdots,$$

and therefore $a_n$ and $b_n$ are strictly increasing functions. Set 

$$q(x) = \begin{cases} a_0, & \text{if } x = a_0, \\ k(x), & \text{if } x \neq a_0. \end{cases}$$

Clearly $q(x)$ is a recursive function and it can be readily shown that $q(x)$ is a regressing function of $a_n$. By replacing $a_0$ by $b_0$ in the de-
finition of \( q(x) \) yields a regressing function of \( b_n \). Hence, \( a_n \) and \( b_n \) are each strictly increasing regressive functions and therefore \( \alpha \) and \( \beta \) are retraceable sets.

Re (b): As a consequence of the definition of the functions \( a_n \) and \( b_n \), we have

\[
\begin{align*}
\alpha & \subset \{ z \mid z = 1 \lor (\exists n)[k^n(z) = 1] \} , \\
\beta & \subset \{ z \mid z = 3 \lor (\exists n)[k^n(z) = 3] \} .
\end{align*}
\]

The sets appearing on the right sides are clearly r.e. Also, since \( k(3) = 0, k(1) = 0 \) and \( k(0) = 0 \), they are disjoint. Hence \( \alpha \upharpoonright \beta \).

Re (c): Suppose that statement (c) were false; this would then mean \( a_n \not\upharpoonright b_n \). Hence there would be a partial recursive function \( p(x) \) such that

\[
(4) \quad (\forall n)[p(a_n) = b_n) \lor (p(b_n) = a_n)] .
\]

Assume that the index of \( p \) in our enumeration is \( i \), i.e., \( p(x) = p_i(x) \).

In view of (4), we would have

\[
p_i(a_i) = b_i \quad \text{or} \quad p_i(b_i) = a_i .
\]

However, according to (3) this statement must be false. This contradiction establishes the desired conclusion that \( a_n \) and \( b_n \) are not \( \upharpoonright \) related.

Re (d): By part (a), each of the sets \( \alpha \) and \( \beta \) is retraceable and hence is either recursive or immune. If one of these sets is recursive then the strictly increasing function ranging over the set would be a recursive function. Thus, if \( \alpha \) were a recursive set then \( a_n \) would be a recursive function. In this event, we would have that

\[
b_n \leq^* n, \text{ since } b_n \text{ is a regressive function},
\]

\[
n \leq^* a_n, \text{ since } a_n \text{ is a regressive function},
\]

and, by the transitivity of the \( \leq^* \) relation, also that \( b_n \leq^* a_n \). By Proposition 1.1 (b), this means that \( a_n \upharpoonright b_n \), which is not possible according to part (c). Therefore \( \alpha \) must be an immune set. In a similar way it can be shown that \( \beta \) is also an immune set. This verifies (d).

To complete the proof, let

\[
A = \text{Req} \alpha \quad \text{and} \quad B = \text{Req} \beta .
\]

By statements (a) and (d) it follows that \( A \) and \( B \) are infinite regressive isols. In addition, combining statements (a) and (c) with the Remark
following Definition 2 implies that $A$ and $B$ are not $\lt$ related. Hence $A$ and $B$ satisfy the requirements of the Theorem.

**Remark A.** In [2, Theorem T2] it is shown that both the collection $\Lambda R$ of all regressive isols and the collection $\Lambda_{cR}$ of all cosimple regressive isols are not closed under addition. We note that the first of these results can be obtained by combining Theorems 1.2 and 1.3.

**Remark B.** It is readily seen from Definitions 1 and 2, that the $\lt$ relation for infinite regressive isols is both reflexive and symmetric. The following Corollary to Theorem 1.3 shows that $\lt$ is a not a transitive relation.

**Corollary.** There exist infinite regressive isols $A$, $B$ and $W$ with $A \lt W$, $B \lt W$, while $A$ and $B$ are not $\lt$ related.

**Proof.** Let $A$ and $B$ be any two infinite regressive isols which are not $\lt$ related. Set $W = \min (A, B)$. Then $W$ is an infinite regressive isol with

$$W \leq^* A \quad \text{and} \quad W \leq^* B.$$ 

Hence, by Theorem 1.1

$$W \lt A \quad \text{and} \quad W \lt B.$$ 

According to our choice of $A$ and $B$, the proof is complete.

**Note 2.** The main results of this note will establish the fact that $A \leq^* B$ (where $A, B \in \Lambda_R$) represents neither a necessary condition nor a sufficient condition for the sum $A + B$ to belong to $\Lambda_R$. In the following discussion we will use the notion of the degree of unsolvability of a regressive isol. This concept is studied in [2]. If $A$ is a regressive isol, then $\Delta_A$ will denote its degree of unsolvability.

**Theorem 2.1.** There exist regressive isols $A$ and $B$ with $A \leq^* B$, yet whose sum $A + B$ is not regressive.

**Proof.** Let $P$ and $Q$ denote two (infinite) regressive isols with different degrees of unsolvability, i.e., $\Delta_P \neq \Delta_Q$. Set

$$A = \min (P, Q).$$ 

Then $A$ is an infinite regressive isol such that

$$A \leq^* P \quad \text{and} \quad A \leq^* Q.$$ 

To complete the proof we need only show that at least one of the two
isols $A + P$ and $A + Q$ is not regressive. To prove this fact, let us suppose otherwise, namely that both $A + P$ and $A + Q$ are regressive isols. Then according to [2, Proposition 17(d)], it follows that

$$\Delta_A = \Delta_P \quad \text{and} \quad \Delta_A = \Delta_Q ,$$

and therefore $\Delta_P = \Delta_Q$. This last equality contradicts our choice of $P$ and $Q$. Hence, either $A + P$ or $A + Q$ is not regressive. If we define $B$ to be $P$ if $A + P \in \Delta_R$ and to be $Q$ otherwise, then $A$ and $B$ will satisfy the requirements of the Theorem.

**Remark.** It is proven in [2] that there are cosimple regressive isols with different degrees of unsolvability. Moreover, the minimum of two cosimple regressive isols is again a cosimple regressive isol. Thus, as a consequence of the previous proof, we see that the following result is also true.

**Theorem.** There exist cosimple regressive isols $A$ and $B$ with $A \leq ^* B$ yet whose sum $A + B$ is not regressive.

**Theorem 2.2.** There exist regressive isols $S$ and $T$ which are incomparable relative to the $\leq ^*$ relation and whose sum is regressive.

**Proof.** This shall be a constructive type of proof and we shall use a technique introduced in the proof of [4, Theorem 95]. The proof will progress in four steps.

**Step I.** In this step we shall define a particular function $a_n$ from $\varepsilon$ into $\varepsilon$, and show that it is strictly increasing and regressive.

Let $p_i(x)$ denote a function of the two variables $i$ and $x$ such that every one-to-one partial recursive function and no other function appears in the sequence $\{p_i\}$. For any numbers $t_0, \ldots, t_m, i$; $\max^* \{p_i(t_0), \ldots, p_i(t_m)\}$ is defined to be 0 if none of the $m + 1$ numbers $p_i(t_0), \ldots, p_i(t_m)$ is defined; and is defined to be the maximum of those numbers $p_i(t_0), \ldots, p_i(t_m)$ which are defined; if at least one of them is defined.

The function $a_n$ is defined by,

$$a_0 = 1 ,$$

$$a_{k+1} = j(a_k, u_{k+1}) ,$$

where

$u_{k+1} = 0$, if either $k = 4n + 1$ or $k = 4n + 3$, 
$u_{k+1} = (\mu y)[j(a_k, y) > \max^* \{p_1(a_0), \ldots, p_n(a_n)\}]$, if either $k = 4n$ or $k = 4n + 2$.

It is readily seen that $a_n$ is an everywhere defined function from $\varepsilon$ into $\varepsilon$. Moreover, just as the function $a_n$ in the proof of Theorem 1.3 was shown to be strictly increasing and regressive, it can be shown that
Step II. Let the four sets \( \delta_0, \delta_1, \delta_2 \) and \( \delta_3 \) denote the ranges of the functions \( a_{4n}, a_{4n+1}, a_{4n+2} \) and \( a_{4n+3} \) respectively. Since each of the functions \( 4n, 4n+1, 4n+2 \) and \( 4n+3 \) is strictly increasing and regressive, it follows that each of the functions \( a_{4n}, a_{4n+1}, a_{4n+2} \) and \( a_{4n+3} \) is regressive. Hence the four sets \( \delta_0, \delta_1, \delta_2 \) and \( \delta_3 \) are each regressive.

We shall now prove:

(a) not \( [\delta_0 = \delta_1] \),

(b) not \( [\delta_1 = \delta_2] \),

(c) \( a_n \) ranges over an immune set.

Re (a): To prove statement (a), let us suppose that it is false. Then, by the enumeration in Step I, there would be a number \( i \) such that

\[
\delta_0 \subset \delta p_i \quad \text{and} \quad p_i(\delta_0) = \delta_1.
\]

One consequence of this fact is

\[
(1) \quad (p_i(a_0), p_i(a_1), \ldots, p_i(a_{i-1})) \subset \delta_1.
\]

By the definition of the function \( a_n \), it follows that \( a_{4i+1} \) would exceed each of the numbers \( p_i(a_0), p_i(a_1), \ldots, p_i(a_{i-1}) \). Since \( a_n \) is strictly increasing, the same would be true for \( a_{4i+1} \) with \( j \geq 1 \). Hence from (1) we can conclude that

\[
(p_i(a_0), p_i(a_1), \ldots, p_i(a_{i-1})) \subset (a_1, a_2, \ldots, a_{4(i-1)+1}).
\]

However, the set on the left side has exactly \( i + 1 \) members while the set on the right side has only \( i \) members. This contradicts the fact that \( p_i \) is a one-to-one function. This means that statement (a) must be true.

Re (b): We can prove statement (b) in a way similar to the one used to prove (a). Assuming that statement (b) is false implies that there is a number \( i \) such that

\[
\delta_1 \subset \delta p_i, \quad \text{and} \quad p_i(\delta_1) = \delta_3,
\]

and

\[
(2) \quad (p_i(a_0), p_i(a_1), \ldots, p_i(a_{4i+2})) \subset \delta_3.
\]

The definition of the function \( a_n \) implies that \( a_{4i+3} \) will exceed each of the numbers \( p_i(a_0), p_i(a_1), \ldots, p_i(a_{4i+2}) \), and since \( a_n \) is strictly increasing, the same will be true for \( a_{4i+3} \) with \( j \geq i \). Hence from (2) we can conclude that
(p_i(a_2), p_i(a_3), \cdots, p_i(a_{i+2})) \subset (a_3, a_4, \cdots, a_{i(i-1)+2}) .

Yet the set on the left side has exactly \( i + 1 \) members while the set on the right side has exactly \( i \) members. This contradicts the fact that \( p_i \) is a one-to-one function. Therefore (b) must be a true statement.

Re (c): Since \( a_n \) is a strictly increasing regressive function it ranges over an infinite retraceable set. We know that this set will be either recursive or immune. But it is easily seen that if \( a_n \) ranges over an infinite recursive set then each of the sets \( \delta_0 \) and \( \delta_1 \) will also be infinite and recursive. According to statement (a), this is not possible. Hence \( a_n \) ranges over an immune set. This verifies (c) and also completes Step II.

Step III. Let
\[
\sigma = \delta_0 + \delta_2 \quad \text{and} \quad \tau = \delta_1 + \delta_2 .
\]

We shall now prove:

(d) \( \sigma \) and \( \tau \) are infinite regressive sets,

(e) \( \sigma \upharpoonright \tau \),

(f) not \( [\sigma \subseteq^* \tau] \),

(g) not \( [\tau \subseteq^* \sigma] \).

For this purpose, let
\[
g(x) = \begin{cases} 4n, & \text{if } x = 2n, \\ 4n + 3, & \text{if } x = 2n + 1, \\ \end{cases}
\]
\[
h(x) = \begin{cases} 4n + 1, & \text{if } x = 2n, \\ 4n + 2, & \text{if } x = 2n + 1. \\ \end{cases}
\]

Then
\[
(3) \quad \rho a_{g(n)} = \sigma \quad \text{and} \quad \rho a_{h(n)} = \tau .
\]

We also note that the functions \( g \) and \( h \) are each recursive and strictly increasing. In addition, their ranges are disjoint and the union of their ranges is \( \varepsilon \).

Re (d): Since both \( g \) and \( h \) are strictly increasing, recursive functions and \( a_n \) is a regressive function it readily follows that both \( a_{g(n)} \) and \( a_{h(n)} \) are regressive function. By (3), this means that \( \sigma \) and \( \tau \) are infinite regressive sets.

Re (e): From the two facts, \( a_n \) is a regressive function, and the ranges of the recursive functions \( g \) and \( h \) are disjoint, one can easily show that the two functions \( a_{g(n)} \) and \( a_{h(n)} \) are separated. This means
that $\sigma$ and $\tau$ are separated sets.

Re (f): Suppose that statement (f) were false, namely assume that $\sigma \leq^* \tau$. According to Proposition (d), this implies that $a_{g(n)} \leq^* a_{h(n)}$. Comparing the definitions of $g(x)$ and $h(x)$, we can conclude from this fact that

$$a_{rn} \leq^* a_{rn+1}.$$

Clearly,

$$a_{rn+1} \leq^* a_{rn},$$

and hence by Proposition (e),

$$a_{rn} \simeq a_{rn+1}.$$

According to Proposition (d), this implies that $\delta_2 \simeq \delta_1$ which is not possible in view of part (a). Therefore statement (f) is true.

Re (g): To verify (g) we can proceed as in the previous case. Suppose that statement (g) is false. This will imply that $\alpha A(w) g* a g(n)$, and this fact gives

$$a_{rn+2} \leq^* a_{rn+3}.$$

Clearly,

$$a_{rn+3} \leq^* a_{rn+2},$$

and hence

$$a_{rn+2} \simeq a_{rn+3}.$$

This means that $\delta_2 \simeq \delta_1$ which is not possible in view of part (b). This contradiction establishes (g) and also completes Step III.

Step IV. Let

$$S = \text{Req } \sigma \quad \text{and} \quad T = \text{Req } \tau.$$

Both $\sigma$ and $\tau$ are infinite subsets of the immune set $\rho a_s$, and therefore are themselves immune sets. Also, by part (d), $\sigma$ and $\tau$ are regressive. Hence

(i) $S$ and $T$ are infinite regressive isols.

Combining [2, Proposition P 10] and statement (f) and (g), implies that

(ii) $S$ and $T$ are incomparable relative to the $\leq^*$ relation.

In view of (i) and (ii), in order to complete the proof it remains only to show that
(iii) $S + T \in A_\mathbb{R}$.

Since $\sigma$ and $\tau$ are separated sets, it follows that $\sigma + \tau \in S + T$. Moreover, $\sigma + \tau$ is a regressive set since $\sigma + \tau = \rho a_n$. Hence $S + T$ is a regressive isol. This verifies (iii) and completes the proof.

REFERENCES

STATE UNIVERSITY OF NEW YORK AT BUFFALO
Mathematical papers intended for publication in the Pacific Journal of Mathematics should be typewritten (double spaced). The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. It should not contain references to the bibliography. Manuscripts may be sent to any one of the four editors. All other communications to the editors should be addressed to the managing editor, Richard Arens at the University of California, Los Angeles, California 90024.

50 reprints per author of each article are furnished free of charge; additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is published monthly. Effective with Volume 16 the price per volume (3 numbers) is $8.00; single issues, $3.00. Special price for current issues to individual faculty members of supporting institutions and to individual members of the American Mathematical Society: $4.00 per volume; single issues $1.50. Back numbers are available.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley 8, California.

Printed at Kokusai Bunken Insatsusha (International Academic Printing Co., Ltd.), No. 6, 2-chome, Fujimi-cho, Chiyoda-ku, Tokyo, Japan.

PUBLISHED BY PACIFIC JOURNAL OF MATHEMATICS, A NON-PROFIT CORPORATION

The Supporting Institutions listed above contribute to the cost of publication of this Journal, but they are not owners or publishers and have no responsibility for its content or policies.
