ON THE BEHAVIOR OF THE SOLUTION OF THE TELEGRAFPHIST’S EQUATION FOR LARGE VELOCITIES

Larry Eugene Bobisud
ON THE BEHAVIOR OF THE SOLUTION OF
THE TELEGRAPHIST'S EQUATION
FOR LARGE VELOCITIES

LARRY E. BOBISUD

Consider the solution \( \phi \) of the inhomogeneous telegraphist's
equation with signal velocity \( \frac{1}{\sqrt{\varepsilon}} \), where \( \phi \) satisfies the initial
conditions \( \phi(x, 0) = g(x), \phi_t(x, 0) = h(x) \). Let \( U \) be the solution
of the parabolic equation that results from the telegraphist's
equation when the velocity is set equal to \( \infty (\varepsilon = 0) \), and let \( U \) satisfy the initial condition \( U(x, 0) = g(x) \). Our main result
is that, under suitable conditions on the coefficients and data,

\[
\int_{-\infty}^{\infty} [\phi(x, t) - U(x, t)]^2 dx = O(\sqrt{\varepsilon})
\]

uniformly in \( 0 \leq t \leq \bar{t} \) for any finite \( \bar{t} \).

We shall investigate the behavior of the solution of the telegra-
phist's equation

\[
\frac{1}{\varepsilon^2} a' \phi_{tt} + b' \phi_t - c' \phi_{xx} = f',
\]

where \( a' > 0, b' > 0, c' > 0 \), as the velocity \( c \) becomes large. For
ease of writing, we will treat explicitly only the case of one space
dimension, although the method employed will obviously extend to
any number of space variables. Since we suppose that \( c' \) is never
zero, we can write the telegraphist's equation in the form

\[
\varepsilon a(x, t) \phi_{tt} + b(x, t) \phi_t - \phi_{xx} = f(x, t),
\]

where \( \varepsilon = 1/c^2 \) is a small parameter. We shall require that the
solution \( \phi \) satisfy the initial conditions

\[
\phi(x, 0) = g(x)
\]

\[
\phi_t(x, 0) = h(x)
\]

for each \( \varepsilon > 0 \). Clearly \( \phi \) depends on \( \varepsilon \); when it is desirable to
make this dependence explicit we shall write either \( \phi \) or \( \phi(x, t; \varepsilon) \),
and similarly for other quantities which may depend on \( \varepsilon \).

If we set \( \varepsilon = 0 \) in eq. (1) we get a parabolic equation

\[
b(x, t) U_t - U_{xx} = f(x, t)
\]
called the degenerate equation corresponding to eq. (1). Since this
equation is of first order in \( t \), we cannot hope to impose both initial
conditions (2) on its solution; but the function $U$ can satisfy the single initial condition

\[(4) \quad U(x, 0) = g(x).\]

If $a, b, f, g, h$ are sufficiently well behaved functions, then, as is well known, eqs. (1), (2) and (3), (4) will form correct problems having unique solutions $\phi_t$ and $U$, respectively. It seems reasonable to expect that $\phi_t \to U$ as $\varepsilon \to 0$, and we shall show that in terms of a certain norm to be introduced this does indeed happen wherever $U$ is defined (normally only for $t \geq 0$). Moreover, as a step in this direction we shall show that, in a certain other norm, $\varphi_t(x, t; \varepsilon) \to U_t(x, t)$ and $\varphi_x(x, t; \varepsilon) \to U_x(x, t)$.

The degeneration of the solution of the pure Cauchy problem for the telegraphist's equation with constant coefficients has been studied by means of the Fourier transform \[1], \[5]. Also, the mixed problem for the equation

$$\varepsilon u_{tt} + \beta(t)u_t - Lu = F(x, t),$$

where $L$ is an elliptic operator whose coefficients do not depend on $t$, has been studied, again using Fourier methods \[4]. In this paper, however, we do not much restrict the coefficients, except that they must of course be positive and sufficiently smooth, and we deal directly with the degeneration by means of an energy-integral technique, rather than by actually constructing the solutions (which are well known to exist) by a Fourier method. However, our estimates are then in an $U$ norm instead of the sup norm.

In the papers referred to above it is shown that, in fact, $\varphi \to U$ and $\varphi_t \to U_t$ pointwise uniformly for $t \in [0, \bar{t}]$, any $\bar{t} > 0$, but that $\varphi_t \to U_t$ pointwise only for $t \in [0, \bar{t}]$ and uniformly only for $t \in [\delta, \bar{t}]$, any $\delta > 0$. This behavior is of course reasonable because at $t = 0$ $\varphi_t = h$, a condition that $U_t$ cannot in general satisfy. No previous studies of the degeneration of the solution of eq. (1) have included considerations for $t < 0$; the technique—reduction to a symmetric linear system—which we shall employ holds also for $t < 0$ provided the solution $U$ of the parabolic problem (3), (4) exists for negative $t$. (This can happen, see \[3], \[1].) We shall not explicitly be concerned with the possibility of negative $t$ in the following, but the argument goes through there if $U$ exists and satisfies the conditions to be imposed.

Concerning the problem (3), (4) we shall assume only that a solution $U$ exists and is smooth enough that $U_{tt}(x, t)$ is continuous and square integrable over the domain $\mathcal{R} = \{(x, t): 0 \leq t \leq \bar{t}\}$ for any $\bar{t} > 0$. This will, for instance, be the case if $b, f,$ and $g$ are suf-
ficiently smooth and, for some constant $\alpha > 0$, $\alpha b - (1/2)b > 0$ holds for all $(x,t) \in \mathcal{R}$; this can be seen by writing eq. (3) as a symmetric positive system in $e^{-at}U$ and $e^{-at}U_x$ for a suitable $\alpha$ (cf. [2]).

We set $\psi = \varphi - U$, where $\varphi$ satisfies eqs. (1), (2) and $U$ satisfies (3), (4), and proceed to determine a problem which $\psi$ satisfies. This is easily seen to be

\begin{align}
(5) \quad & \varepsilon a \psi_{tt} + b \psi_t - \psi_{xx} = -\varepsilon a U_{tt} \\
(6) \quad & \psi(x, 0) = 0 \\
& \psi_t(x, 0) = h(x) - U_t(x, 0),
\end{align}

the inhomogeneous telegraphist's equation with inhomogeneous data of a special form. It is this problem for $\psi$ that we shall consider in detail.

We introduce the following inner products and corresponding norms, in terms of which our results will be formulated. For vectors $u = (u_1, u_2)$ and $v = (v_1, v_2)$ we set $(u, v) = u'v = u_1v_1 + u_2v_2$, where $u'$ is the transpose of $u$; for functions (i.e., 1-vectors), we set $(u, v) = uv$. Which of these inner products is meant will always be clear from the context. If for fixed $t$, $u$ and $v$ are square integrable in $x$, we set

\[(u, v)_t = \int_{-\infty}^{x} (u(x, t), v(x, t)) dx;\]

if moreover $u$ and $v$ are integrable over the domain

\[\mathcal{R} = \{(x, t) : -\infty < x < \infty, 0 \leq t \leq T\},\]

we set

\[(u, v)_\mathcal{R} = \int_{0}^{T} (u, v) dt = \int \int_{\mathcal{R}} (u(x, t), v(x, t)) dx dt.\]

As customary, we set $(u, u)_t = \|u\|_{1,t}^2$, $(u, u)_\mathcal{R} = \|u\|_{\mathcal{R}}^2$.

Our main result is then

**THEOREM.** Let $a, b, f, g, h$ be sufficiently smooth and $f, g, h$ in $L^1(\mathcal{R})$. In addition, let $b$ and $a$ satisfy the condition that for some $\varepsilon_0 > 0$ and some $\delta > 0$ the inequality

\[2b - \varepsilon a \geq 2\delta\]

holds for all $(x, t) \in \mathcal{R}$ and all $\varepsilon \in (0, \varepsilon_0]$. The smoothness conditions on the coefficients and data are such that a $C^2(\mathcal{R})$ and $L^1(\mathcal{R})$ solution $\varphi$ of (1), (2) exists with $\varphi_t$ and $\varphi_x$ also in $L^1(\mathcal{R})$ and that a $C^2(\mathcal{R})$ solution $U$ of (3), (4) exists such that $U_{tt}$ satisfies the same
conditions as were imposed on \( f \) for a suitable solution of (1), (2) to exist. These conditions being met, we have

\[ ||\psi ||_t = ||\varphi - U||_t = 0(\sqrt{\varepsilon}) \]

uniformly for \( 0 \leq t \leq \bar{t}, \) any \( \bar{t} \) finite.

As noted above, the proof is easily modified so that the theorem holds for negative \( t, \) provided a sufficiently well behaved solution of the degenerate problem exists for \( t < 0. \)

The smoothness conditions which the coefficients must satisfy may be found, for instance, by reducing the problem to a symmetric linear system of first-order equations, as in [2].

As a step in establishing this theorem we shall first prove the following lemma.

**Lemma.** Under the conditions of the Theorem,

\[ ||\psi_x||_\infty = 0(\varepsilon), \]

\[ ||\psi_x||_\infty = 0(\varepsilon). \]

We begin by writing eq. (5) as a system in the two variables \( u_1 = e^{-\lambda t}\psi_t \) and \( u_2 = e^{-\lambda t}\psi_x \) for a \( \lambda \) to be determined. In terms of \( u = (u_1, u_2) \) this system is

\[
Lu = \begin{pmatrix} \varepsilon a & 0 \\ 0 & 1 \end{pmatrix} u_t + \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} u_x + \begin{pmatrix} \varepsilon a \lambda + b & 0 \\ 0 & \lambda \end{pmatrix} u = \begin{pmatrix} -\varepsilon a e^{-2t} U_t \\ 0 \end{pmatrix};
\]

the initial data for \( u \) are clearly

\[
u(x, 0; \varepsilon) = \begin{pmatrix} h(x) - U_t(x, 0) \\ 0 \end{pmatrix}.
\]

Defining the matrix \( k \) as

\[
k = \begin{pmatrix} \varepsilon a \lambda + b & 0 \\ 0 & \lambda \end{pmatrix} - \frac{1}{2} \begin{pmatrix} \varepsilon a_t & 0 \\ 0 & 0 \end{pmatrix},
\]

we wish to determine \( \lambda \) so that \( 1/2(k + k'), \) where \( k' \) denotes the transpose of \( k, \) is positive definite. But for \( \lambda = \delta, \) where \( \delta \) is the constant of the theorem, we have

\[
\frac{1}{2} u'(k + k')u = u'ku = \left[ \varepsilon a \lambda + \frac{1}{2} (2b - \varepsilon a_t) \right] u^2_t + \lambda u_x^2 \geq \lambda u'u;
\]

whence, moreover,
(u, ku) ≤ λ \| u \|^2 \),

an inequality which will be needed later.

Following Friedrichs [2], and using the "divergence theorem" and the fact that \( Lu \) can be written as

\[
Lu = \frac{1}{2} \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} u_t + \left[ \frac{1}{2} \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} u \right]
+ \frac{1}{2} \begin{pmatrix}
0 & -1 \\
-1 & 0
\end{pmatrix} u_x + \left[ \frac{1}{2} \begin{pmatrix}
0 & -1 \\
-1 & 0
\end{pmatrix} u \right] + ku,
\]

we calculate \((u, Lu)\) for any two-vector \( u \in C^1(\mathbb{R}) \) which, together with its first derivatives, is in \( L^2(\mathbb{R}) \):

\[
(u, Lu) = \frac{1}{2} \int \int \left[ \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} (u, u_t) + \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} \right] dx dt + (u, ku)

\]

\[
= \frac{1}{2} \int \int \left[ \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} u_i + \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} \right] dx dt + (u, ku)

\]

\[
= \frac{1}{2} \int_{-\infty}^{\infty} \left( \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} u \right) \bigg|_{t=0} dx

+ \frac{1}{2} \int_{-\infty}^{\infty} \left( \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} u \right) \bigg|_{t=\tau} dx + (u, ku).

\]

Thus we have, since \( \begin{pmatrix}
\varepsilon a & 0 \\
0 & 1
\end{pmatrix} \) is clearly positive definite for each \( \varepsilon > 0 \),

\[
(u, Lu) + \frac{1}{2} \int_{-\infty}^{\infty} (u(x, 0), \begin{pmatrix}
\varepsilon a(x, 0) & 0 \\
0 & 1
\end{pmatrix} u(x, 0) dx \geq (u, ku)

\]

for any continuously differentiable \( u \) which, together with its first partial derivatives, is in \( L^2(\mathbb{R}) \). By choice of \( \lambda \) we have \((u, ku) \geq \lambda \| u \|^2 \), so we get

\[
(9) \quad \| u \| \| Lu \| + \frac{1}{2} \int_{-\infty}^{\infty} (u(x, 0), \begin{pmatrix}
\varepsilon a(x, 0) & 0 \\
0 & 1
\end{pmatrix} u(x, 0) dx \geq \lambda \| u \|^2.

\]

It is this energy inequality which yields the lemma. For we can write the solution \( u \) of problem (7), (8) as \( u = v + w \), where \( v \) satisfies the homogeneous equation with inhomogeneous data and \( w \) satisfies the inhomogeneous equation but homogeneous data. For \( w \) inequality (9) yields

\[
\| Lw \| \geq \varepsilon \| e^{-i\varepsilon t} \| U_t \| \geq \lambda \| w \| \,
\]
whence also

$$\varepsilon \| aU_{tt} \| \geq \lambda \| w \|_\mathcal{A} ;$$

from this it is clear that

$$\| w \|_\mathcal{A} = 0(\varepsilon) ,$$

which at once yields the weaker statement

$$\| w \|_\mathcal{A} = (\sqrt{\varepsilon}) .$$

Similarly for $v$ we have

$$\frac{\varepsilon}{2} \int_{-\infty}^{\infty} a(x, 0)(h(x) - U_t(x, 0))^2 dx \geq \lambda \| v \|_\mathcal{A}^2 ,$$

whence

$$\| v \|_\mathcal{A} = 0(\sqrt{\varepsilon}) .$$

Thus $\| u \|_\mathcal{A} = 0(\sqrt{\varepsilon})$. But $u = (e^{-\lambda t} \psi_t, e^{-\lambda t} \psi_x)' = e^{-\lambda t} \psi_0$, say, and it follows that $\| \psi_0 \|_\mathcal{A} = 0(\sqrt{\varepsilon})$. Since

$$\| \psi_0 \|_\mathcal{A}^2 = \int \int \psi_t^2 + \psi_x^2 = \| \psi_t \|_\mathcal{A}^2 + \| \psi_x \|_\mathcal{A}^2$$

we conclude that

$$\| \psi_t \|_\mathcal{A} = 0(\sqrt{\varepsilon}), \| \psi_x \|_\mathcal{A} = 0(\sqrt{\varepsilon}) ,$$

completing the proof of the lemma.

The theorem is an easy consequence of the lemma and the following simple estimate:

$$\left[ \int_0^t f(\tau) d\tau \right]^2 \leq \int_0^t f^2(\tau) d\tau .$$

For we have

$$\| \psi \|_l^2 = \left( \int_0^t \psi_t dt \right)^2 = \int \int \left\{ \int_0^t \psi_t dt \right\}^2 dx \leq t \int \int \psi_t^2 dt dx$$

$$\leq \bar{t} \int \int \psi_t^2 dt dx = \bar{t} \| \psi_t \|_\mathcal{A}^2 = [0(\sqrt{\varepsilon})]^2$$

for any $t_0 \in [0, \bar{t}]$. Hence the theorem is established.

**Remark.** The lemma and theorem proved above are equally true for the mixed boundary-initial value problem with homogeneous boundary data. For our entire proof has depended only upon the existence of the energy estimate eq. (9), which in turn depends only
on writing the problem (5), (6) as a symmetric linear system with admissible boundary-initial conditions. Since that can be done for the mixed problem as well as for the pure Cauchy problem for the case at hand [2], the theorem is equally true in both cases.

It should also be observed that the considerations used here can doubtless be used in studying the degeneration of the solutions of other problems which can be written as symmetric linear systems with admissible boundary-initial data.

I wish to thank Professor Reuben Hersh for several stimulating conversations.
