**A GENERALIZED COROLLARY OF THE BROWDER-KIRK  
FIXED POINT THEOREM**

WILLIAM GRADY DOTSON, JR. AND W. R. MANN

## A GENERALIZED COROLLARY OF THE BROWDER-KIRK FIXED POINT THEOREM

By W. G. DOTSON, JR. AND W. ROBERT MANN

**This paper generalizes a corollary, due to W. A. Kirk, of the F. E. Browder-W. A. Kirk fixed point theorem for non-expansive self-mappings of closed, bounded, convex sets in uniformly convex Banach spaces.**

F. E. Browder [1] and W. A. Kirk [4] have independently proved that if  $F$  is a closed, bounded, convex subset of a uniformly convex Banach space, and if  $T$  is a nonexpansive mapping from  $F$  into  $F$ , then  $T$  has a fixed point in  $F$ . The following corollary was proved by Kirk [4] and also by Browder and Petryshyn [2]: If  $E$  is a uniformly convex Banach space, and  $T: E \rightarrow E$  is a nonexpansive mapping, and if for some  $x_1 \in E$  the sequence  $\{T^n x_1\}$  of Picard iterates of  $T$  is bounded, then  $T$  has a fixed point in  $E$ . Browder and Petryshyn also observed that if the nonexpansive mapping  $T$  has a fixed point in  $E$ , then for any  $x_1 \in E$  the sequence  $\{T^n x_1\}$  will be bounded. Outlaw and Groetsch [6] have recently announced the following extension of this corollary: If  $E$  is a uniformly convex Banach space, and  $T: E \rightarrow E$  is a nonexpansive mapping, and  $S_\lambda = \lambda I + (1 - \lambda)T$  for a given  $\lambda, 0 < \lambda < 1$ , then  $T$  has a fixed point in  $E$  if and only if the sequence  $\{S_\lambda^n x_1\}$  of Picard iterates of  $S_\lambda$  is bounded for each  $x_1 \in E$ . The purpose of this note is to show that this corollary and its extension are both special cases of a considerably more general corollary of the Browder-Kirk theorem.

W. R. Mann [5] introduced the following general iterative process: Suppose  $A = [a_{np}]$  is an infinite real matrix satisfying (1)  $a_{np} \geq 0$  for all  $n, p$ , and  $a_{np} = 0$  for  $p > n$ ; (2)  $\sum_{p=1}^n a_{np} = 1$  for each  $n$ ; (3)  $\lim_n a_{np} = 0$  for each  $p$ . If  $F$  is a closed convex subset of a Banach space  $E$ , and  $T: F \rightarrow F$  is a continuous mapping, and  $x_1 \in F$ , then the process  $M(x_1, A, T)$  is defined by

$$v_n = \sum_{p=1}^n a_{np} x_p, \quad x_{n+1} = T v_n, \quad n = 1, 2, 3, \dots$$

Various choices of the matrix  $A$  yield many interesting iterative processes as special cases. With  $A$  the infinite identity matrix, one gets the Picard iterates of  $T: v_{n+1} = x_{n+1} = T v_n$ , whence  $v_{n+1} = T^n v_1 = T^n x_1$ . With  $0 < \lambda < 1$  and  $A = [a_{np}]$  defined by  $a_{np} = \lambda^{n-1}$  if  $p = 1$ ,  $a_{np} = \lambda^{n-p}(1 - \lambda)$  if  $1 < p \leq n$ ,  $a_{np} = 0$  if  $p > n$ ,  $n = 1, 2, 3, \dots$ , one gets  $v_{n+1} = \lambda v_n + (1 - \lambda)T v_n = S_\lambda v_n$ , whence  $v_{n+1} = S_\lambda^n v_1 = S_\lambda^n x_1$ . If  $T$  is linear then an appropriate choice of  $A$  yields

$$v_{n+1} = (x_1 + Tx_1 + \dots + T^n x_1)/(n + 1),$$

thus providing a connection with mean ergodic theorems for linear operators. Another choice of  $A$  yields an iterative process recently investigated by Halpern [3], provided  $x_1 = 0$ . Many other choices are possible, of course. Our main theorem is as follows.

**THEOREM 1.** *If  $E$  is a uniformly convex Banach space, and if  $T: E \rightarrow E$  is a nonexpansive mapping, and if there exist  $x_1 \in E$  and a process  $M(x_1, A, T)$  such that either of the sequences  $\{x_n\}, \{v_n\}$  is bounded, then  $T$  has a fixed point in  $E$ .*

To prove this, we will make use of the following lemma which is a straightforward consequence of uniform convexity.

**LEMMA 1.** *Suppose  $E$  is a uniformly convex Banach space, and suppose  $r > 0$ . For each  $\varepsilon > 0$  let  $p_\varepsilon = \sup \{s: s = \|u - v\| \text{ where } u, v \in E, \|u\| = 2r, 2r < \|v\| \leq 2r + \varepsilon, \text{ and } \|(1 - t)u + tv\| > 2r \text{ for all } t \in (0, 1)\}$ . Given any  $c > 0$ , there exists  $\varepsilon > 0$  such that  $p_\varepsilon \leq c$ .*

*Proof of Theorem 1.* We first observe that if either of the sequences  $\{x_n\}, \{v_n\}$  in the process  $M(x_1, A, T)$  is bounded, then the other is also bounded. For if  $\|x_n\| \leq b$  for all  $n$ , then

$$\|v_n\| = \left\| \sum_{p=1}^n a_{np} x_p \right\| \leq \sum_{p=1}^n a_{np} \|x_p\| \leq b \sum_{p=1}^n a_{np} = b$$

for all  $n$ ; and if  $\|v_n\| \leq b$  for all  $n$ , then

$$\|x_{n+1} - T(0)\| = \|T(v_n) - T(0)\| \leq \|v_n - 0\| \leq b$$

for all  $n$ . So, given  $x_1 \in E$  and a process  $M(x_1, A, T)$  in which both of the sequences  $\{x_n\}, \{v_n\}$  are bounded, we wish to show that  $T$  has a fixed point. This will be done by showing that  $T$  maps a certain bounded, closed, convex set into itself. We use the notation  $D_r(p) = \{x: \|x - p\| \leq r\}$ ,  $r > 0, p \in E$ . Let  $r > 0$  be such that  $x_n \in D_r(0)$  and  $v_n \in D_r(0)$  for all  $n$ . For each  $i = 1, 2, 3, \dots$ , define sets  $C_i$  and  $G_i$  by

$$C_i = \bigcap_{n=i}^{\infty} D_{2r}(x_n), \quad G_i = \bigcap_{n=i}^{\infty} \{D_{2r}(x_n) \cap D_{2r}(v_n)\}.$$

For each  $i$ , we have

$$D_r(0) \subset G_i \subset C_i \subset D_{2r}(x_i) \subset D_{3r}(0).$$

Each  $C_i$  and each  $G_i$  is a nonempty bounded, closed, convex set, and it is clear that  $C_i \subset C_{i+1}$  and  $G_i \subset G_{i+1}$ . We now show  $T(G_i) \subset C_{i+1}$ :  $x \in G_i$  implies  $\|x - v_n\| \leq 2r$  for all  $n \geq i$ , which gives  $\|Tx - Tv_n\| \leq$

$\|x - v_n\| \leq 2r$  for all  $n \geq i$ ; but, since  $x_{n+1} = Tv_n$ , this can be written  $\|Tx - x_{n+1}\| \leq 2r$  for all  $n \geq i$ , so that  $Tx \in C_{i+1}$ . Define sets  $C$  and  $G$  by

$$C = \bigcup_{i=1}^{\infty} C_i, G = \bigcup_{i=1}^{\infty} G_i.$$

Clearly,  $D_r(0) \subset G \subset C \subset D_{3r}(0)$ ; and  $\bar{G}, \bar{C}$  are bounded, closed, convex sets. Since  $T(G_i) \subset C_{i+1}$  for each  $i$ , we have  $T(G) \subset C$ . Since  $T$  is continuous,  $T(\bar{G}) \subset \overline{T(G)} \subset \bar{C}$ . The proof will be completed by showing  $C \subset \bar{G}$ , so that  $T(\bar{G}) \subset \bar{C} \subset \bar{G}$  (i.e.,  $T$  maps the bounded, closed, convex set  $\bar{G}$  into itself). Since  $C = \bigcup_{i=1}^{\infty} C_i$ , it suffices to show that for each  $i, C_i \subset \bar{G}$ . Suppose  $i$  is a given positive integer, and  $x \in C_i$ . We wish to show that  $x \in \bar{G}$ . The first step toward this end is set off as the following lemma.

**LEMMA 2.** *For each  $\varepsilon > 0$  there exists a positive integer  $j_\varepsilon \geq i$  such that  $x \in \bigcap_{n=j_\varepsilon}^{\infty} \{D_{2r}(x_n) \cap D_{2r+\varepsilon}(v_n)\} = F_{j_\varepsilon}$ .*

*Proof of Lemma 2.* Since  $x \in C_i$  we have  $\|x - x_p\| \leq 2r$  for all  $p \geq i$ . For all  $n \geq i$  we have

$$\|x - v_n\| = \left\| \sum_{p=1}^n a_{np}x - \sum_{p=1}^n a_{np}x_p \right\| = \left\| \sum_{p=1}^n a_{np}(x - x_p) \right\|$$

so that

$$\|x - v_n\| \leq \sum_{p=1}^n a_{np} \|x - x_p\| = \sum_{p=1}^{i-1} a_{np} \|x - x_p\| + \sum_{p=i}^n a_{np} \|x - x_p\|,$$

whence, for all  $n \geq i$ ,

$$\|x - v_n\| \leq \left( \sum_{p=1}^{i-1} a_{np} \right) \cdot \max_{1 \leq p \leq i-1} \|x - x_p\| + 2r.$$

Since  $i$  and  $x$  are fixed, and since  $\lim_n a_{np} = 0$  for each  $p = 1, 2, \dots, i-1$ , it is clear that for any  $\varepsilon > 0$  there exists a positive integer  $j_\varepsilon \geq i$  such that  $\|x - v_n\| \leq 2r + \varepsilon$  for all  $n \geq j_\varepsilon$ . But  $n \geq j_\varepsilon \geq i$  also implies  $\|x - x_n\| \leq 2r$  since  $x \in C_i$ . Hence  $n \geq j_\varepsilon$  implies

$$x \in D_{2r}(x_n) \cap D_{2r+\varepsilon}(v_n),$$

and so  $x \in \bigcap_{n=j_\varepsilon}^{\infty} \{D_{2r}(x_n) \cap D_{2r+\varepsilon}(v_n)\} = F_{j_\varepsilon}$ .

*Proof of Theorem 1 continued.* We return now to the final problem of showing  $x \in \bar{G}$  (see immediately before Lemma 2). Given any  $c > 0$ , choose  $\varepsilon > 0$  such that  $p_\varepsilon \leq c$  (this can be done by Lemma 1, in which  $r > 0$  is taken as the  $r$  we are using in this proof). For

this  $\varepsilon$ , there exists a positive integer  $j_\varepsilon \geq i$  such that  $x \in F_{j_\varepsilon}$  (by Lemma 2). We will show  $G_{j_\varepsilon} \cap D_c(x) \neq \phi$ . Since  $c$  is arbitrary, this will show  $x \in \bar{G} = (\bigcup_{i=1}^\infty G_i)^-$ . We suppose  $G_{j_\varepsilon} \cap D_c(x) = \phi$  and obtain a contradiction. Since  $0 \in D_r(0) \subset G_{j_\varepsilon}$ ,  $0 \notin D_c(x)$ , and so  $0 < c/\|x\| < 1$ . Let  $t_1 = 1 - (c/\|x\|)$ . Then  $0 < t_1 < 1$  and  $\|t_1x - x\| = (1 - t_1)\|x\| = c$ . Since  $t_1x \in D_c(x)$ , we have  $t_1x \notin G_{j_\varepsilon}$ . Now  $x \in F_{j_\varepsilon} \subset \bigcap_{n=j_\varepsilon}^\infty D_{2r}(x_n) = C_{j_\varepsilon}$ , and since  $C_{j_\varepsilon}$  also contains 0 and is convex,  $t_1x \in C_{j_\varepsilon}$ . Since  $t_1x \notin G_{j_\varepsilon}$  and  $t_1x \in C_{j_\varepsilon}$ , we have  $t_1x \notin \bigcap_{n=j_\varepsilon}^\infty D_{2r}(v_n)$ . Let  $n$  be a positive integer,  $n \geq j_\varepsilon$ , such that  $t_1x \notin D_{2r}(v_n)$ . Let

$$t_2 = \sup \{t: 0 < t < 1 \text{ and } tx \in D_{2r}(v_n)\}.$$

This set of  $t$ 's is nonempty since  $D_r(0) \subset D_{2r}(v_n)$ . Since  $D_{2r}(v_n)$  is closed, we have  $t_2x \in D_{2r}(v_n)$ ; and it is easily seen from the definition of  $t_2$  that we must have  $\|t_2x - v_n\| = 2r$ . If  $t_2 \geq t_1$ , then, since 0 and  $t_2x$  are in the convex set  $D_{2r}(v_n)$ , we would have  $t_1x \in D_{2r}(v_n)$  which is not true. Hence  $t_2 < t_1$ . Similarly we have  $\|x - v_n\| > 2r$ , since 0 is in the convex set  $D_{2r}(v_n)$  and  $t_1x$  is not. Since  $x \in F_{j_\varepsilon}$  and since  $n \geq j_\varepsilon$ ,  $x \in D_{2r+\varepsilon}(v_n)$ , so we have  $2r < \|x - v_n\| \leq 2r + \varepsilon$ . Next we observe that if  $t \in (0, 1)$

$$\|(1 - t)(t_2x - v_n) + t(x - v_n)\| = \|[ (1 - t)t_2 + t \cdot 1 ]x - v_n\| > 2r$$

since  $t_2 < (1 - t)t_2 + t \cdot 1 < 1$  so that  $[ (1 - t)t_2 + t \cdot 1 ]x \notin D_{2r}(v_n)$ . With  $u = t_2x - v_n$  and  $v = x - v_n$  we now have  $\|u\| = 2r$ ,  $2r < \|v\| \leq 2r + \varepsilon$ , and  $\|(1 - t)u + tv\| > 2r$  for all  $t \in (0, 1)$ . Hence  $\|u - v\| = \|t_2x - x\| \leq p_\varepsilon$  (see Lemma 1). But  $\varepsilon$  was chosen so that  $p_\varepsilon \leq c$ . So we have

$$\|t_2x - x\| = (1 - t_2)\|x\| \leq p_\varepsilon \leq c.$$

This gives  $t_2 \geq 1 - (c/\|x\|) = t_1$ , which is a contradiction.

For completeness, we include the following theorem which is somewhat stronger than the converse of Theorem 1.

**THEOREM 2.** *If  $E$  is a normed linear space, and if  $T: E \rightarrow E$  is a nonexpansive mapping, and if  $T$  has a fixed point  $p \in E$ , then for any  $x_1 \in E$  and any process  $M(x_1, A, T)$ , the sequences  $\{x_n\}, \{v_n\}$  are bounded.*

*Proof.* For each  $n = 1, 2, 3, \dots$ , we have

$$\begin{aligned} \|x_{n+1} - p\| &= \|Tv_n - Tp\| \leq \|v_n - p\| = \left\| \sum_{j=1}^n a_{nj}(x_j - p) \right\| \\ &\leq \sum_{j=1}^n a_{nj} \|x_j - p\| \leq \max_{j=1, \dots, n} \|x_j - p\|. \end{aligned}$$

Thus  $\|x_2 - p\| \leq \|x_1 - p\|$ ,  $\|x_3 - p\| \leq \max_{j=1,2} \|x_j - p\| = \|x_1 - p\|$ , etc., so that we have  $\|x_j - p\| \leq \|x_1 - p\|$  for all  $j = 1, 2, 3, \dots$ ; and hence with  $b = \|x_1 - p\| + \|p\|$  we get  $\|x_j\| = \|(x_j - p) + p\| \leq \|x_j - p\| + \|p\| \leq b$  for all  $j = 1, 2, 3, \dots$ . Finally,

$$\|v_n\| = \left\| \sum_{j=1}^n a_{nj} x_j \right\| \leq \sum_{j=1}^n a_{nj} \|x_j\| \leq b \cdot \sum_{j=1}^n a_{nj} = b$$

for all  $n = 1, 2, 3, \dots$ .

Mathematical papers intended for publication in the *Pacific Journal of Mathematics* should be in typed form or offset-reproduced, double spaced with large margins. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. It should not contain references to the bibliography. Manuscripts, in duplicate if possible, may be sent to any one of the four editors. All other communications to the editors should be addressed to the managing editor, Richard Arens, University of California, Los Angeles, California 90024.

Each author of each article receives 50 reprints free of charge; additional copies may be obtained at cost in multiples of 50.

---

The *Pacific Journal of Mathematics* is published monthly. Effective with Volume 16 the price per volume (3 numbers) is \$8.00; single issues, \$3.00. Special price for current issues to individual faculty members of supporting institutions and to individual members of the American Mathematical Society: \$4.00 per volume; single issues \$1.50. Back numbers are available.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley 8, California.
