IDEAL STRUCTURE IN GENERALIZED GROUP ALGEBRAS

KJELD LAURSEN
IDEAL STRUCTURE IN GENERALIZED GROUP ALGEBRAS

KJELD B. LAURSEN

We study the algebra $L^i(G, A)$ of Bochner-integrable functions from a locally compact topological group $G$ to a Banach algebra $A$. First we characterize closed ideals in $L^i(G, A)$ as subspaces that are translation invariant in a certain sense (Theorem 2.2). After that we establish some generalizations of Wiener's tauberian theorem. The class of algebras under consideration consists of strongly semi-simple and completely regular Banach algebras. After this, in §3, we deal with spectral synthesis. Our main result (Corollary 3.6) states that if $A$ does not admit spectral synthesis then neither does $L^i(G, A)$. In §4 we apply the theory of completely regular, strongly semi-simple Banach algebras to obtain some conditions sufficient to ensure that a given ideal is the intersection of the maximal regular ideals containing it.

An introduction to the theory of tensor products of vector spaces can be found in several places, for instance in [16] or [5]. The question of norming a tensor product is treated in the references mentioned; the greatest cross norm $\gamma$ is defined there. We include a definition for completeness.

**Definition 1.1.** Let $E_1$, $E_2$ be normed vector spaces and suppose $t \in E_1 \otimes E_2$. We define the greatest cross norm $\gamma$ by

$$\gamma(t) = \inf \sum |x_i| |y_i|$$

with inf taken over all representatives $\sum x_i \otimes y_i = t$. The completion of $E_1 \otimes E_2$ with respect to $\gamma$ is denoted by $E_1 \overline{\otimes} E_2$.

The following structure theorems will be used extensively in this paper, sometimes without explicit mention. Proposition 1.4 provides one of the major justifications for the study of vector valued group algebras.

**Proposition 1.2 [5].** Let $G$ be a locally compact group and $A$ a Banach algebra. Then

$$L^i(G, A) = L^i(G) \otimes A$$

where $\otimes$ denotes an isometric isomorphism.

**Remark 1.3.** In [5, p. 59] proposition 1.2 is proved when $A$ is
a vector space. However, it is not difficult to extend the validity of the result to algebras.

**Proposition 1.4.** Let $G$ and $H$ be locally compact groups. Then

$$L^1(G \times H) = L^1(G) \otimes L^1(H).$$

Proposition 1.4 is a special case of Proposition 1.2 via the identification $L^1(G \times H) = L^1(G, L^1(H))$ (Cf. [20]).

2. Ideal structure. Tauberian theorems. If $G$ is a locally compact group the following theorem about closed one-sided ideals in $L^1(G)$ holds (Cf. e.g., [14, p. 374]):

A closed subspace $I$ of $L^1(G)$ is a left (right) ideal if and only if it is invariant under left (right) translations, i.e., if and only if $x(\cdot) \in I \Rightarrow x(g \cdot) \in I$ for every $g \in G$.

Grove [6] has shown that this assertion is not valid in a generalized group algebra. Here we show that if we consider a different concept of translation the theorem is true. We make the following definition.

**Definition 2.1.** We say that a subspace $I$ of $L^1(G, A)$ ($G$ is a locally compact group, $A$ a Banach algebra) is left $A$-translation invariant if

1. $x(\cdot) \in I \Rightarrow x(g \cdot) \in I$ for every $g \in G$
2. $x(\cdot) \in I \Rightarrow ax(\cdot) \in I$ for every $a \in A$.

Analogously, we define right $A$-translation invariance by replacing (i) by

(i') $x(\cdot) \in I \Rightarrow x(\cdot g_0) \in I$ for every $g_0 \in G$

and (ii) by

(ii') $x(\cdot) \in I \Rightarrow x(\cdot)a \in I$ for every $a \in A$.

We can then prove the following

**Theorem 2.2.** Let $G$ be a locally compact group and $A$ a Banach algebra with approximate identity. A closed subspace $I$ of $L^1(G, A)$ is a left (right, 2-sided) ideal if and only if $I$ is left (right, left and right) $A$-translation invariant.

**Proof.** We prove this for a left ideal. So let $I$ be a closed left ideal. Using the notation $x_\cdot$ for the function $x(g \cdot)$ and letting $\{w^\cdot\}$ be an approximate identity for $L^1(G, A)$ we have (as in the numerical case) that
so that for $x \in I$

$$x_{g_0} = \lim (u^a*x)_{g_0} = \lim (g_{g_0}^{-1}*x) \in I.$$  

This shows that $x \in I \Rightarrow x_g \in I$ for every $g \in G$. The proof of (ii), Definition 2.1 is as follows

$$x \in I, a \in A \Rightarrow aw^a*x \in I$$

$$\lim aw^a*x \in I$$

$$\alpha \lim w^a*x = ax \in I.$$  

Thus we have shown that a closed left ideal in $L^i(G, A)$ is left $A$-translation invariant.

The proof of the converse implication is based on approximation by means of a sort of Riemann sums.

Let $I$ be a closed subspace of $L^i(G, A)$ such that $I$ is left $A$-translation invariant. We must show that $x \in I, y \in L^i(G, A) \Rightarrow y*x \in I$. Since $I$ is closed and continuous functions with compact support are dense in $L^i(G, A)$ it suffices to show that $x \in I \Rightarrow y*x \in I$ for any continuous $y \in L^i(G, A)$ with compact support. So let $y$ be such a function with support $K$. From what is given about $I$ it follows that

$$\alpha y(g_0)x_{g_0} \in I \quad \text{for any } g_0 \in G \text{ and } \alpha \in C.$$  

But

$$y*x = \int_g y(g')x_{g'}^{-1}dg' = \int_K y(g')x_{g'}^{-1}dg'$$

and the last term can be approximated arbitrarily well by sums of the form

$$\sum_k y(g_k)x_{g_k}.$$  

This can be seen in the following way: as in the numerical case we can show that $x_g$ is a continuous function of $g$ with respect to the norm in $L^i(G, A)$. Since $y$ is continuous it follows easily that $y(g)x_g$ is continuous (here we use pointwise multiplication). Moreover, $y(g)x_g = 0$ outside $K$. From the compactness of $K$ and the uniform continuity of $y(g)x_g$ on $K$ it follows that corresponding to a given $\varepsilon > 0$ there are finitely many measurable disjoint sets $K_i (i = 1, 2, \cdots, n)$ such that $g', g'' \in K_i \Rightarrow |y(g')x_{g'} - y(g'')x_{g''}| < \varepsilon$. If we choose $g_i \in K_i$, and define
φ(g) = \sum_{i=1}^{n} 1_{K_i}(g)y(g_i)x_{g_i}(g) \quad g \in K

where $1_{K_i}$ is the characteristic function of $K_i (i = 1, \ldots, n)$ then $\phi$ is clearly integrable; moreover, an application of Fubini’s theorem yields that

\[
\int_{\mathbb{R}} \left| \int_K y(g')x_{g'-i}(g')dg' - \sum_k \int_{K_k} y(g_k)x_{g_k-i}(g)\mu(K_k) \right|dg \\
= \sum_k \int_{K_k} \int_{\mathbb{R}} |y(g')x_{g'-i}(g') - y(g_k)x_{g_k-i}(g)|dg'dg \\
\leq \sum_k \int_{K_k} \int_{\mathbb{R}} |y(g')x_{g'-i}(g') - y(g_k)x_{g_k-i}(g)|dg dg' \\
< \sum_k \int_{K_k} \varepsilon dg' = \varepsilon \sum_k \int_{K_k} dg' = \varepsilon \mu(K).
\]

Since $I$ is closed this shows that $y*x \in I$, i.e., $I$ is a left ideal. This proves the theorem.

From the proof of Theorem 2.2 we get

**Corollary 2.3.** If $x_1, x_2 \in L(G, A)$ and $\varepsilon > 0$ is given then there is a finite sum $h$ of $A$-translations of $x_1$ such that $|x_1*x_2 - h| < \varepsilon$.

Later, when we get to the spectral synthesis we shall make use of Theorem 2.2. However, as a kind of introduction to the spectral synthesis we shall concern ourselves with a special case, namely various formulations of Wiener’s tauberian theorems and the extensions of these to generalized group algebras. It is well known that an important step in one standard proof of the so-called generalized Wiener’s tauberian theorem is a proof of the fact that if $G$ is a locally compact abelian group then every closed proper ideal in $L(G)$ is contained in a maximal regular ideal. A necessary condition that $L(G, A)$ have this property is that the range algebra $A$ have it (see Corollary 3.5).

Therefore, we are led to the theory of the so-called tauberian algebras which we define as follows (cf. [21]).

**Definition 2.4.** A Banach algebra $A$ is tauberian if every closed proper 2-sided ideal has a nonempty hull, i.e., if every proper closed 2-sided ideal is contained in a maximal regular 2-sided ideal.

Apparently the theory of these algebras is not yet very extensive;
the results that are of interest in this context make one or two other assumptions about the algebras in question. Consequently, we start out by considering these concepts, i.e., that of strong semi-simplicity and that of complete regularity.

**Definition 2.5.** Let $A$ be an algebra. The strong structure space $RS(A)$ is the collection of all maximal regular 2-sided ideals in $A$ with the hull-kernel topology. The strong radical, $R_s(A)$ is defined by

$$R_s(A) = \bigcap_{M \in RS(A)} M.$$

If $R_s(A) = \{0\}$, $A$ is strongly semi-simple.

Let $B_1$ and $B_2$ be Banach-algebras, $B_3 = B_1 \otimes B_2$. Following [4] we define

$$T: J_1 \times J_2 \longrightarrow J_3$$

where $J_i$ is the collection of closed 2-sided modular ideals in $B_i (i = 1, 2, 3)$ and

$$\tilde{T}: RS(B_1) \times RS(B_2) \longrightarrow RS(B_1 \otimes B_2).$$

Let $(I_1, I_2) \in J_1 \times J_2$ and define

$$R: B_1 \otimes B_2 \longrightarrow B_1/I_1 \otimes B_2/I_2$$

by

$$t = \sum x_i \otimes y_i \in B_1 \otimes B_2 \mapsto R(t) = \sum x_i/I_1 \otimes y_i/I_2 \in B_1/I_1 \otimes B_2/I_2.$$

Then

$$T(I_1, I_2) = \text{kernel}(R).$$

It is not difficult to see that $T(I_1, I_2) \in J_3$. If

$$(M_1, M_2) \in RS(B_1) \times RS(B_2) \subset J_1 \times J_2$$

then let $M_3 \in RS(B_1 \otimes B_2)$ be a maximal modular ideal containing $T(M_1, M_2)$ and define

$$\tilde{T}(M_1, M_2) = M_3.$$

$T$ and $\tilde{T}$ are defined in [4] without use of the blanket assumption of that paper that $B_1$ and $B_2$ have identities. Clearly, therefore, Lemma 2 [4] holds; moreover Theorem 1 [4] shows that $\tilde{T}$ is closed when the hull-kernel topology is used. If $B_1$ and $B_2$ have identities $\tilde{T}$ is injective [4]; if $B_1$ or $B_2$ is commutative $\tilde{T}$ is injective and sur-
jective even when no identities are present [12]. It is not known to the author whether $\tilde{T}$ has these two properties in general. Generally, we shall assume $\tilde{T}$ to have these properties, i.e., to be bijective.

About strongly semi-simple generalized group algebras we have the following immediate generalization of [12, Corollary 1]:

**THEOREM 2.6.** Let $G$ be a locally compact group, $A$ a Banach algebra. Assume $\tilde{T}: RS(L'(G)) \times RS(A) \to RS(L'(G, A))$ to be bijective. Then $L'(G, A)$ is strongly semi-simple if and only if $L'(G)$ and $A$ are strongly semi-simple.

Next, we turn to the completely regular algebras. Following [21] we have

**DEFINITION 2.7.** A Banach algebra $A$ is completely regular if $RS(A)$ satisfies these conditions:

(i) $RS(A)$ is Hausdorff;

(ii) For every $M \in RS(A)$ there is an open set $0$ such that $M \in 0 \subset RS(A)$ and such that $k(0)$ is a regular ideal (here $k$ denotes kernel).

In [21, p. 178] it is shown that the above conditions are equivalent to the single condition that $RS(\tilde{A})$ be Hausdorff, where $\tilde{A}$ is the smallest Banach algebra with identity containing $A$.

We first prove

**THEOREM 2.8.** If $B_1$ and $B_2$ are completely regular Banach algebras and if $\tilde{T}$ is injective then

$$\tilde{T}: RS(B_1) \times RS(B_2) \longrightarrow RS(B_1 \otimes B_2)$$

is a homeomorphism so that if $\tilde{T}$ is bijective then $B_1 \otimes B_2$ is completely regular.

**Proof.** Let $O_i$ be an open set in $RS(B_i)$ for which $k(O_i) = I_i$ is a regular ideal, $i = 1, 2$. Such sets exist in abundance by Definition 2.7 ii). The closure of $O_i = k(k(O_i)) = k(I_i)$ is a compact set [15, Th. 2.6.4]. Let $0 = \tilde{T}(0_i \times 0_i)$. We first show that $0$ has compact closure. Again using [15, Th. 2.6.4] this will be accomplished by showing that $k(0)$ is a regular ideal. We use the mapping $T$ and Lemma 2 of [4]: $T(I_i, I_2)$ is a regular ideal and if we can show that $T(I_i, I_2) \subset k(0)$ then $k(0)$ is regular. But
\[ T(I_1, I_2) \subseteq \bigcap_{M_i \in O_i} T(M_i, M_2) \]
\[ \subseteq \bigcap_{M_i \in O_i} T(M_i, M_2) \]
\[ = \bigcap_{M \in O} M = k(0) . \]

Therefore \( h(k(0)) \) is a compact set. Now, since \( B_1, B_2 \) are completely regular \( h(k(0_i)) \times h(k(0_2)) \) is Hausdorff. \( \overline{T}(h(k(0_i)) \times (h(k(0_2)))) \) is closed in the relative topology of \( \overline{T}(RS(B_1) \times RS(B_2)) \) so

\[ h(k(0)) \cap \overline{T}(h(k(0_i)) \times h(k(0_2))) \]

is compact in this topology. Moreover,

\[ T^{-1}(h(k(0))) \cap \overline{T}(h(k(0_i)) \times h(k(0_2))) \]

is a Hausdorff space with interior:

\[ (M_1, M_2) \in 0_i \times 0_2 \implies \overline{T}(M_1, M_2) \in h(k(0)) \cap \overline{T}(h(k(0_i)) \times h(k(0_2))) \]
\[ \implies (M_1, M_2) \in T^{-1}(h(k(0))) \cap \overline{T}(h(k(0_i)) \times h(k(0_2))) . \]

It follows that \( \overline{T} \mid T^{-1}(h(k(0))) \cap \overline{T}(h(k(0_i)) \times h(k(0_2))) \) is continuous so that \( \overline{T} \mid 0_i \times 0_2 \) is continuous. \( 0_i \times 0_2 \) is open; we have shown that \( \overline{T} \) is a homeomorphism.

If \( \overline{T} \) is surjective, then clearly \( RS(B_1 \otimes B_2) \) is Hausdorff. If \( M = \overline{T}(M_1, M_2) \in RS(B_1 \otimes B_2) \) then there are open sets \( O_i \) with regular kernels such that \( M_i \in O_i (i = 1, 2) \). \( \overline{T}(0_i \times 0_2) = 0 \) is an open set containing \( M \) and \( k(0) \) is regular by the first part of the above argument.

Consequently, \( B_1 \otimes B_2 \) is completely regular.

Theorem 2.8 will be used in Theorem 2.10. Just as in the numerical case it is of importance in our proof of the Wiener-Tauberian theorem to be able to conclude that the elements vanishing outside compact sets in the strong structure space are dense. This notion will be made precise by means of the following definition [21].

**Definition 2.9.** Let \( B \) be a Banach algebra; for \( S \subset RS(B) \) define

\[ J(S, B) = \{ x \in B; x(M) = 0 \in B/M \} \]
for all \( M \) in some open set containing \( S \)

and

\[ J(\infty, B) = \{ x \in B; x(M) = 0 \in B/M \} \]
for every \( M \) outside some compact set in \( RS(B) \).

If no confusion seems likely, we use the notation \( J(S) \) and \( J(\infty) \).
**Theorem 2.10.** Let $B_1$ and $B_2$ be completely regular Banach algebras and suppose $\bar{T}$ is bijective. Using $-\bar{\ }$ to denote norm closure we have the following implication:

\[
\begin{align*}
J(\infty, B_i)^{-} & = B_i \\
J(\infty, B_1 \otimes \gamma B_2)^{-} & = B_1 \otimes \gamma B_2.
\end{align*}
\]

**Proof.** The proof of this statement is not hard. Since $B_1 \otimes B_2$ is dense in $B_1 \otimes \gamma B_2$, it suffices to consider elements of the form $x \otimes y$. So let $\epsilon > 0$ and $x \otimes y \in B_1 \otimes B_2$ be given. From the assumptions we get that $\exists x_1 \in B_1$ and a compact set $F_1 \subset RS(B_1)$ such that $x_1(M_1) = 0$ for $M_1 \in F_1$ and such that $|x - x_1| < \epsilon$. Similarly, $\exists y_1 \in B_2$ and a compact set $F_2 \subset RS(B_2)$ such that $y_1(M_2) = 0$ for $M_2 \in F_2$ and $|y - y_1| < \epsilon$. $\gamma$ being a crossnorm we get immediately that

\[
\gamma(x \otimes y - x_1 \otimes y_1) \leq \epsilon(|x| + |y| + \epsilon).
\]

Now, since $B_1$ and $B_2$ are completely regular

\[
\bar{T}: RS(B) \times RS(B_2) \longrightarrow RS(B_1 \otimes \gamma B_2)
\]

is continuous (Theorem 2.8) so $\bar{T}(F_1 \times F_2)$ is compact.

If $M \in \bar{T}(F_1 \times F_2)$ and $M = \bar{T}(M_1, M_2)$ then it follows first that $M_1 \in F_1$ or $M_2 \in F_2$ and next that $x_1 \otimes y_1(M) = x_1(M_1) \otimes y_1(M_2) = 0$. From this the theorem follows.

Now we are ready to combine the three concepts mentioned so far (tauberianism, strong semi-simplicity and complete regularity) in a proof of a ideal theoretic formulation of Wiener’s tauberian theorem.

**Theorem 2.11.** Let $G$ be a locally compact group such that $L^1(G)$ is strongly semi-simple, tauberian and completely regular and let $A$ be a strongly semi-simple, completely regular, tauberian Banach algebra. Suppose $\bar{T}$ is bijective. Then $L^1(G, A)$ is strongly semi-simple, completely regular and tauberian.

**Proof.** Theorems 2.8 and 2.6. show that $L^1(G, A)$ is strongly semi-simple and completely regular. In [21] it is shown that under these circumstances $J(\infty, L^1(G, A))^{-}$ is the uniquely determined minimal closed 2-sided ideal with empty hull [21, Th. 1.2]. By the same token, $J(\infty, A)^{-}$ is a closed 2-sided ideal with empty hull. Since $A$ is tauberian $J(\infty, A)^{-}$ cannot be proper, i.e., $J(\infty, A)^{-} = A$. Similarly,

\[
J(\infty, L^1(G))^{-} = L^1(G).
\]

But then (Theorem 2.10) $J(\infty, L^1(G, A))^{-} = L^1(G, A)$, i.e., no closed proper 2-seided ideal in $L^1(G, A)$ has an empty hull. Thus $L^1(G, A)$ is tauberian.
$\tilde{T}$ is bijective if $G$ is locally compact and abelian [12]. Consequently, we also have

**Corollary 2.12.** [20]. If $G$ is a locally compact abelian group and $C$ is a compact group, then the conclusion of Theorem 2.11 holds for $L'(G \times C)$.

*Proof.* $L'(C)$ is strongly semi-simple, completely regular and tauberian [21].

3. Spectral synthesis. A well known interpretation of 2.11 views it as an answer to a special case of the question of spectral synthesis: is a closed 2-sided ideal in a Banach algebra the intersection of the maximal regular 2-sided ideals containing it? Using the hull-kernel terminology and notation, Theorem 2.11 says that with certain conditions on $L'(G)$ and $A$ our ideal $I \subseteq L'(G, A)$ satisfies $I = k(h(I))$ if $h(I) = \emptyset$ (because then $I = L'(G, A)$).

If $I = k(h(I))$ for every closed 2-sided ideal in a Banach algebra $B$ we say that $B$ admits spectral synthesis. Schwartz (in [17]) has shown that $L'(E^n)$ does not admit spectral synthesis. In this section we shall prove some results along these lines for $L'(G, A)$. The main result is that if $A$ does not admit spectral synthesis then $L'(G, A)$ does not, either.

**Lemma 3.1.** Let $G$ be a locally compact group and $A$ a Banach algebra. Let $I$ be a closed 2-sided ideal in $A$ and define

$$J_I = \{ f \in L'(G, A); f(g) \in I \text{ a.e. } g \in G \}$$

$J_I$ is a closed 2-sided ideal.

**Remark 3.2.** The definition of $J_I$ should be interpreted as follows: Pick a function representative $f'$ of the equivalence class of functions $f \in L'(G, A)$; if $f'(g) \in I$ for a.e. $g \in G$ then $f \in J_I$.

**Proof of Lemma 3.1.** Clearly $J_I$ is a subspace. If $f_n \to f$ in $L'(G, A)$-norm then there is a subsequence $f_{n_k}$ converging to $f$ a.e. Since $I$ is closed this implies that $J_I$ is closed.

Consequently, to show that $J_I$ is an ideal we need only check the $A$-translation invariance of $J_I$ (Theorem 2.2). (Note that no approximate identity is needed when we use Theorem 2.2 here.) But the $A$-translation invariance of $J_I$ is an immediate consequence of the definition of $J_I$ and the fact that $I$ is an ideal.
Remark 3.3. Clearly, in Lemma 3.1, “2-sided” could be replaced by “left” or “right”.

Lemma 3.4. With the assumptions of Lemma 3.1, let $I$ be a proper closed 2-sided ideal in $A$ and $J_1$ the corresponding ideal in $L^1(G, A)$.

Then

$$\tilde{T}(RS(L^1(G)) \times h(I)) \subseteq h(J_1).$$

If $\tilde{T}$ is bijective, then

$$h(J_1) = \tilde{T}(RS(L^1(G)) \times h(I))$$

so that

$$k(h(J_1)) = J_1 \quad k(h(I)) = I.$$

Proof. We shall show that if $I_1 \subseteq L^1(G)$ is a modular 2-sided ideal and if $I_2 \supseteq I$ is a modular 2-sided ideal in $A$, then $T(I_1I_2) \supseteq J_1$.

We make the following observations: If $I''$ is any closed 2-sided ideal in $A$, then we can consider $L^1(G, A/I'')$. Any $f \in L^1(G, A)$ induces a mapping $f \mapsto f_{I''}$ by

$$f_{I''}(g) = f(g)/I'' \quad \text{a.e. } g \in G.$$

Clearly,

$$J_{I''} = \{f \in L^1(G, A) | f_{I''} = 0\}.$$

If $I'$ is a closed 2-sided ideal in $L^1(G)$ and $B$ is any Banach algebra, we have a mapping

$$\alpha^B_f : L^1(G) \otimes B \longrightarrow L^1(G)/I' \otimes B,$$

i.e., a mapping

$$L^1(G, B) \longrightarrow L^1(G)/I' \otimes B$$

defined by

$$\alpha^B_f(\sum x_i \otimes y_i) = \sum x_i/I' \otimes y_i$$

for any $\sum x_i \otimes y_i \in L^1(G, B)$.

If $(I', I'')$ is a pair of modular ideals, then

$$T(I', I'') = \text{kernel}(\alpha^{I'/I''}_f \circ (f \mapsto f_{I''})).$$

Now the above claim follows easily: If $I_1 \subseteq L^1(G)$ is a modular 2-sided ideal and $I_2 \supseteq I$ is a modular ideal, then
\[ f \in J_I \implies f \in \text{kernel}(f \longrightarrow f_{I_2}) \]
\[ \implies f \in \text{kernel}(\alpha^{I_1/I} \circ (f \longrightarrow f_{I_2})) \]
\[ \implies f \in T(I_1, I_2). \]

With this proved, the lemma follows from the general properties of \( T \) and \( \widetilde{T} \):

If \( M_2 \in h(I), M_1 \in RS(L'(G)) \) then
\[ \widetilde{T}(M_1, M_2) \equiv T(M_1, M_2) \equiv J_I \]
so
\[ (*) \quad \widetilde{T}[RS(L'(G)) \times h(I)] \equiv h(J_I). \]

If \( \widetilde{T} \) is bijective, then it is a simple matter to show that if \( M_3 \in h(J_I) \), then
\[ \widetilde{T}^{-1}(M_3) = (M_1, M_2) \]
has the property that \( M_2 \equiv I \), so that
\[ (**) \quad \widetilde{T}^{-1}(h(J_I)) \equiv RS(L'(G)) \times h(I). \]
Combining (*) and (**) the second claim of the lemma follows:
\[ (***) \quad h(J_I) = \widetilde{T}(RS(L'(G)) \times h(I)). \]

To get the last statement of the lemma, we replace \( I \) by \( k(h(I)) \) in (***):
\[ h(J_{k(h(I))}) = T(RS(L'(G)) \times h(k(I))) \]
\[ = T(RS(L'(G)) \times h(I)) \]
\[ = h(J_I). \]

Therefore
\[ k(h(J_{k(h(I))})) = k(h(J_I)) \]
\[ \equiv J_{k(h(I))} \equiv J_I, \]
from which we conclude immediately that if
\[ k(h(J_I)) = J_I \]
then
\[ k(h(I)) = I. \]

The following corollaries are straightforward.
COROLLARY 3.5. If \( \tilde{T} \) is bijective and if \( I \) is a closed 2-sided ideal in \( A \) which is contained in no maximal regular ideal then the same is true about \( J_I \).

COROLLARY 3.6. If \( \tilde{T} \) is bijective, then \( L'(G, A) \) does not admit spectral synthesis if \( A \) does not.

COROLLARY 3.7. Let \( G \) be a locally compact group and \( E^n \) \( n \)-dimensional Euclidean space (considered an additive group). \( L'(G \times E^n) \) does not admit spectral synthesis if \( n \geq 3 \).

Proof. [17], Proposition 1.4, and Corollary 3.6.
If we add the assumption that \( G \) be abelian, Lemma 3.5 can be strengthened.

LEMMA 3.8. Suppose \( G \) is a locally compact abelian group and \( A \) is a Banach algebra. If \( I \) is a closed proper 2-sided ideal, then

\[
k(h(J_I)) = J_I \quad \text{if and only if} \quad k(h(I)) = I.
\]

Proof. It is not difficult to show that if \( M_1 \) is a maximal regular ideal in \( L'(G) \) and \( \chi \) the corresponding character on \( G \) then \( M_1 \) defines a mapping

\[
\varphi_{M_1} : L'(G, A) \longrightarrow A
\]
given by

\[
\varphi_{M_1}(\sum x_i \otimes y_i) = \sum_i (x_i) y_i
\]

for every \( \sum x_i \otimes y_i \in L'(G) \otimes_r A = L'(G, A) \) and that this mapping has the integral expression

\[
\varphi_{M_1}(f) = \int_G f(g) \chi(g) dg \quad \text{for all} \quad f \in L'(G, A).
\]

Next, we note that if \( M \in RS(L'(G, A)) \) and \( \tilde{T}(M) = (M_1, M_2) \), then

\[
f \in M \quad \Longleftrightarrow \quad \varphi_{M_1} f \in M_2. \quad [12].
\]

To complete the proof we must show that

\[
f \in k((\tilde{T}(M_i, M_2) ; M_2 \in h(I))) \quad \Longrightarrow \quad f \in J_I
\]

under the assumption that \( k(h(I)) = I \). Using the definition of \( J_I \) and \( k(h(I)) = I \) we see that we must prove the following implication:

\[
\varphi_{M_i}(f) \in I \quad \text{for any} \quad M_i \in RS(L'(G))
\]

\[
\Longrightarrow f(g) \in I \quad \text{for a.a.} \quad g \in G.
\]
So, suppose
\[ \varphi_{M_1}(f) = \int_G f(g)\chi(g)dg \in I \]
for every character \( \chi \) on \( G \). By means of the approximation theorem for abelian groups (cf. e.g., [14, Corollary 4, p. 406]) we get that
\[ (\ast) \quad \int f(g)\psi(g)dg \in I \]
for every continuous function \( \psi : G \to \mathbb{C} \) with compact support. If \( f \) is continuous a well known argument will show that \( f(g) \in I \) for every \( g \in G \).

To cover the general case we let \( \{u_\alpha\} \) be an approximate identity in \( L^1(G) \) consisting of continuous functions with compact support. Using standard results from the numerical case and Proposition 1.2. we conclude first that \( u_\alpha*f \to f \) in \( L^1(G, A) \)-norm and next that \( u_\alpha*f \) is continuous for every \( \alpha \). From \( \{u_\alpha*f\} \) we can pick a sequence and from this a subsequence converging a.e. to \( f \). Consequently, it suffices to show that \( (u_\alpha*f)(g) \in I \) for every \( g \in G \). But
\[
\begin{align*}
  u_\alpha*f(g) &= \int_G u_\alpha(g_1)f(g^{-1}g)dg_1 \\
  &= \int_G u_\alpha(gh^{-1})f(h)dh \in I
\end{align*}
\]
because of (\ast). This completes the proof.

Just as in [8] we can extract the following corollaries.

**Corollary 3.9.** If \( G \) is abelian and \( A \) is a Banach algebra, the only maximal regular 2-sided ideals containing \( J_{M_2} \) with \( M_2 \in RS(A) \) are of the form \( T(M_1, M_2) \) where \( M_1 \) is an arbitrary regular maximal 2-sided ideal in \( L^1(G) \).

**Corollary 3.10.** Same assumptions as in Corollary 3.9. Suppose \( M'_1, M''_1 \in RS(A) \) and \( M'_2 \neq M''_2 \); then
\[
(\overline{T(M_1, M'_2)} + J_{M''_2})^- = L^1(G, A)
\]
(where \( - \) denotes norm closure) for any \( M_1 \in RS(L^1(G)) \).

4. On sets of spectral synthesis. Turning to more positive assertions about spectral synthesis we shall study \( L^1(G, A) \) in the case where \( L^1(G) \) and \( A \) are strongly semi-simple and completely regular. The situation in which a certain weak form of spectral synthesis holds will dominate this section.
**Definition 4.1.** Let $A$ be an algebra. A closed set $S \subseteq RS(A)$ is said to be a set of spectral synthesis if $S$ uniquely determines a closed ideal $I$ such that $\bar{h}(I) = S$. Clearly then $I = k(h(I))$, i.e., $I = k(h(I))$.

**Definition 4.2.** A Banach algebra $A$ in which singleton sets in $RS(A)$ are sets of spectral synthesis is called an $N^*\text{-algebra}$ [21]. An ideal $I$ for which $h(I)$ consists of just one point is a primary ideal. Consequently, an $N^*$-algebra is a Banach algebra in which closed primary ideals are maximal regular.

The following proposition generalizes Theorem 4 in [8] and will be used to investigate conditions under which $L^i(G, A)$ is an $N^*$-algebra.

**Proposition 4.3.** Let $G$ be a locally compact group and $A$ a commutative Banach algebra. Suppose $I \subseteq L^i(G, A)$ is a closed 2-sided ideal such that $I \supseteq I_{x_0}$ for some $x_0 \in RS(A)$. Let $h(I) = \{\bar{T}(M', M'')\}$. If $W = \{M'; \bar{T}(M', M'') \in h(I) \text{ for some } M'' \in RS(A)\}$ is a set of spectral synthesis then $h(I)$ is a set of spectral synthesis, i.e. $I = k(h(I))$.

**Proof.** From Lemma 3.4 (i) we get that

$$h(I) \subseteq h(I_{x_0}) \subseteq \{\bar{T}(M_1, M_2); M_2 \in h(M_0), M_1 \in RS(L^i(G))\}$$

$$= \{\bar{T}(M_1, M_0); M_1 \in RS(L^i(G))\}.$$ 

i.e., $h(I) = \bar{T}(W, M_0)$

with a slight abuse of notation.

Now, using the notation of the proof of Lemma 3.8, $x_0 \in RS(A)$ defines a homomorphism

$$\varphi_{x_0}: L^i(G, A) \to L^i(G)$$

by

$$f = \sum x_i \otimes y_i \in L^i(G, A) \Rightarrow \varphi_{x_0} f = \sum x_0(y_i)x_i \in L^i(G).$$

We consider the image of $I$ under $\varphi_{x_0}$, i.e., let

$$K = \varphi_{x_0}(I).$$

We wish to show that $K$ is a closed 2-sided ideal in $L^i(G)$. Since $\varphi_{x_0}$ is a homomorphism onto it is clear that $K$ is an ideal; to show that $K$ is closed we prove that if $x_0$ is an identity modulo $M_0$ then

$$K = \{x \in L^i(G); x \otimes u_0 \in I\}.$$ 

If this equation holds it is elementary to show that $K$ is closed:

$$\{x_n\} \subseteq K, x_n \to x_0 \Rightarrow x_n \otimes u_0 \to x_0 \otimes u_0 \in I \text{ (since } I \text{ is closed) } \Rightarrow x_0 \in K.$$
So suppose \( x \otimes u_0 \in I \); then \( \varphi_{M_0}(x \otimes u_0) = x \in K \). Conversely, \( x \in K \Rightarrow \exists f \in I \) such that \( \varphi_{M_0}f = x \). Consider \( f - x \otimes u_0 = f(g) - x(g)u_0 \in M_0 \) for \( a.a.g \in G \) since if \( f = \sum x_i \otimes y_i \) then

\[
M_0(f(g) - x(g)u_0) = \sum x_i(g)M_0(y_i) - M_0(y_i)x_i(g) = 0
\]

From the definition of \( I_{M_0} \) it follows that \( f - x \otimes u_0 \in I_{M_0} \), i.e., \( f - x \otimes u_0 \in I \) (note, incidentally, that \( f - \varphi_{M_0}f \otimes u_0 \in I_{M_0} \) for every \( f \in L(G, A) \)). But since \( f \in I \) it follows that \( x \otimes u_0 \in I \). This proves that \( K = \{x \in L(G); x \otimes u_0 \in I\} \), and thus that \( K \) is a closed 2-sided ideal (not necessarily \( \neq \{0\} \)).

The above characterization of \( K \) together with the definition of the mapping \( \overline{T} \) readily yield the fact that \( h(K) = W \). But since \( f \in I \) if and only if \( \varphi_{M_0}f \in K = k(W) \) it follows that \( f \in I \) if and only if \( M \otimes M_0f = M_{(M_0f)} = 0 \) for every \( M \in W \), i.e., \( f \in I \) if and only if \( f \in k(h(I)) \). This proves the proposition.

Using proposition 4.3, we can obtain a sufficient condition for \( L^i(G, A) \) to be an \( N^* \)-algebra.

**Theorem 4.4.** Let \( G \) be a locally compact group such that \( L^i(G) \) is completely regular, strongly semi-simple and tauberian and let \( A \) be a commutative, completely regular, (strongly) semi-simple Banach algebra. If \( L^i(G) \) and \( A \) are \( N^* \)-algebras, then so is \( L^i(G, A) \).

**Proof.** We must show that if \( I \) is a primary closed 2-sided ideal, e.g., \( h(I) = \{M_0 = \overline{T}(M_0', M''_0)\} \) then \( I = M_0 \). Since \( L^i(G, A) \) is strongly semi-simple and completely regular (Theorems 2.6 and 2.10) we can assume without loss of generality that \( I = (J(M_0) \cap J(\infty))^- \) [21, p. 180]. We wish to apply Proposition 4.3; consequently, we must show that \( I \supset I_{M_0''} \).

So let \( f \in I_{M_0''} \); we first show that we can approximate \( f \) by means of continuous functions in \( I_{M_0''} \). \( f \in I_{M_0''} \Rightarrow f(g) \in M_0'' \) for \( a.a.g \in G \). If \( \{u_0\} \) is an approximate identity in \( L^i(G) \) consisting of continuous functions then

\[
u_0^\alpha f(\cdot) = \int g u_\alpha(g')f(g'^{-1}\cdot)dg',
\]

is continuous and

\[
u_0^\alpha f \to f \quad \text{as} \ \alpha \to \infty.
\]

Moreover, since \( f(g) \in M_0'' \) for \( a.a.g \in G \), \( u_\alpha(g')f(g'^{-1}g) \in M_0'' \) for...
a.a.g, \( g' \in G \). An approximation argument similar to the one employed in the proof of Theorem 2.2. then yields that \( u^*f(g) \in M''_6 \) for a.a.g \( \in G \), i.e., \( u^*f \in I_{M''_6} \).

Since we want to show that \( f \in I_{M''_6} \) \( \Rightarrow f \in I \) and since \( I \) is closed we can assume therefore, without any loss of generality, \( f \in I_{M''_6} \) to be continuous.

So let \( f \in I_{M''_6} \) be a given continuous function and let also \( \varepsilon > 0 \) be given. \( \exists \) compact set \( E \subset G \) such that

\[
\int_{g \in E} |f(g)| \, dg < \frac{\varepsilon}{2}.
\]

Let \( g_0 \in E \) and consider \( f(g_0) \in M''_6 \) (\( f(g) \in M''_6 \) for every \( g \in G \) since \( f \) is continuous). \( A \) is assumed to be a semi-simple completely regular \( N^* \)-algebra so \( \exists \ y_{g_0} \) such that

\[
|f(g_0) - y_{g_0}| < \frac{\varepsilon}{2t\mu(E)}
\]

and \( M''(y_{g_0}) = 0 \) for all \( M'' \) in a neighborhood \( N_{g_0} \) of \( M''_6 \) and outside a compact set \( C_{g_0} \subset RS(A) \). Let

\[
S_{g_0} = \left\{ g ; |f(g) - y_{g_0}| < \frac{\varepsilon}{2t\mu(E)} \right\}.
\]

Since \( f \) is continuous \( S_{g_0} \) is an open neighborhood of \( g_0 \). Clearly, \( \{S_{g_0}, g_0 \in E\} \) is an open cover of \( E \) and so has a finite subfamily covering \( E \).

Let the open sets covering \( E \) be \( \{S_i\}_{i=1}^n \), let the appropriate points \( y_{g_0} \) be \( \{y_i\}_{i=1}^n \) and let the corresponding neighborhoods and compact sets in \( RS(A) \) be \( \{N_i\}_{i=1}^n \) and \( \{C_i\}_{i=1}^n \), respectively. Define

\[
T_1 = S_1 \cap E
\]

\[
T_i = \left( S_i \setminus \bigcup_{j<i} S_j \right) \cap E \quad i = 2, \ldots, n;
\]

then \( T_i \cap T_j = \emptyset \) if \( i \neq j \) and \( \bigcup_{i=1}^n T_i = E \). Let \( 1_{T_i} \) be the characteristic function of \( T_i(i = 1, \ldots, n) \). If we define

\[
f' = \sum_{i=1}^n 1_{T_i} \otimes y_i
\]

then, clearly, \( f' \in L'(G, A) \). Moreover, \( M(f') = 0 \) for every

\[
M \in \left\{ \tilde{T}(M', M''); M' \in RS(L'(G)), M'' \in \left( \bigcap_{i=1}^n N_i \right) \cup (RS(A) \setminus \bigcup_{i=1}^n C_i) \right\}
\]

i.e., \( M(f') \) vanishes in a neighborhood of \( M_6 \).
\[ |f - f'| = \int_E |f(g) - f'(g)| \, dg = \int_E |f(g) - \sum_{i=1}^n 1_{T_i}(g)y_i| \, dg \\
+ \int_{E \setminus E} |f(g)| \, dg < \sum_{i} \int_{T_i} |f(g) - \sum 1_{T_i}(g)y_i| \, dg + \varepsilon/2 \\
= \sum_i \int_{T_i} |f(g) - y_i| \, dg + \varepsilon/2, \text{ since } T_i \cap T_j = \emptyset \text{ if } i \neq j \\
\sum_i \frac{\varepsilon}{2\mu(E)} \mu(T_i) + \varepsilon/2 = \varepsilon.

It remains to note that each \( 1_{T_i} \) can be approximated by an element \( x_i \) from \( J(\infty, L^1(G)) \), (because \( L^1(G) \) is tauberian) i.e., \( 1_{T_i} \otimes y_i \) can be approximated by \( x_i \otimes y_i \) \( (i = 1, \ldots, n) \). Since the sum is finite it follows that \( \sum x_i \otimes y_i \in J(\infty, L^1(G, A)) \cap J(M_0, L^1(G, A)) \).

We have shown that \( I_{M_0} \subset I \). From Proposition 4.3. we get that since \( \{M'\}_0 \) is a set of spectral synthesis \( (L^1(G) \text{ is an } N^*\text{-algebra}) \)

\[ I = k(h(I)) = M_0. \]

This proves that \( L^1(G, A) \) is an \( N^*\)-algebra.

**REMARK 4.5.** In [10] it is shown that if \( G \) is a locally compact abelian group and \( C \) is a compact group then \( L^1(G \times C) \) is an \( N^*\)-algebra. This result is contained in Theorem 4.4.

Incidentally, if the tensor product \( B \otimes C \) of two Banach algebras is an \( N^*\)-algebra then it is possible to give a direct description of the mapping \( \bar{T} : RS(B) \times RS(C) \to RS(B \otimes C) \).

**PROPOSITION 4.6.** Suppose \( B \otimes C \) is an \( N^*\)-algebra, and suppose \( \bar{T} \) is bijective. Let \( M_i \in RS(B), M_2 \in RS(C) \) and consider

\[ I_{M_1} = \{ x \otimes y; x \in M_1, y \in C \} \]
\[ I_{M_2} = \{ x \otimes y; x \in B, y \in M_2 \}. \]

Let \( M = \bar{T}(M_1, M_2) \). If we use the symbol \( [ \ ] \) to denote the ideal generated by the set inside the brackets then

\[ M = [I_{M_1} + I_{M_2}]^-. \]

**SKETCH OF PROOF.** Because of the assumption on \( B \otimes C \) it suffices to show that \( [I_{M_1} + I_{M_2}]^- \) is primary (clearly \( [I_{M_1} + I_{M_2}]^- \subset M \)). To show that \( [I_{M_1} + I_{M_2}]^- \) is a primary ideal a slight variation of the argument used in the proof of Lemma 4.7. can be used. Therefore, we omit all further details.

With the notation of Proposition 4.6. we have the following

**LEMMA 4.7.** Suppose \( B \) and \( C \) are strongly semi-simple and
completely regular Banach algebras, and suppose $\tilde{T}$ is bijective. Let $M = \tilde{T}(M_1, M_2) \in RS(B \otimes \mathcal{C}, C)$ be given. Then
\[
I_0 = [J(M_1) \cap J(\infty, B) \otimes J(\infty, C) + J(\infty, B) \otimes J(M_2) \cap J(\infty, C)]
\]
\[
= (J(M) \cap J(\infty, B \otimes \mathcal{C})).
\]

**Proof.** Since $B$ and $C$ are completely regular, $\tilde{T}$ is a homeomorphism (Theorem 2.10). Therefore, if
\[
x \otimes y \in (J(M_1) \cap J(\infty, B)) \otimes J(\infty, C)
\]
it is clear that $x \otimes y \in J(\infty, B \otimes \mathcal{C})$. Moreover, $x \in J(M_1) \cap J(\infty, B) \subset J(M_1) \Rightarrow \exists$ open neighborhood $N(M_i)$ such that $x(M_i') = 0$ for all $M_i' \in N(M_i)$. $\tilde{T}(N(M_1) \times RS(C))$ is an open neighborhood of $M$ in $RS(B \otimes \mathcal{C})$ and $x \otimes y(M_i') = x(M_i') \otimes y(M_i') = 0$ for every
\[
M' = \tilde{T}(M_1', M_2') \in \tilde{T}(N(M_1) \times RS(C)).
\]
This shows that $J(M_1) \cap J(\infty, B) \otimes J(\infty, C) \subset J(M) \cap J(\infty, B \otimes \mathcal{C})$. Repeating this argument we get that
\[
I_0 \subset J(M) \cap J(\infty, B \otimes \mathcal{C}).
\]
Because of the remark at the bottom of p. 180 of [21] to prove equality it suffices to show that $I_0$ is a primary ideal. So suppose $x \otimes y \in M' = \tilde{T}(M_1', M_2')$ for all $x \in J(M_1) \cap J(\infty, B), y \in J(\infty, C)$. We can choose $y_0 \in J(\infty, C)$ such that $y_0 \in M_2$ [21, Corollary 1.2.2.]. Since $x \otimes y_0 \in M'$ for all $x \in J(M_1) \cap J(\infty, B)$ it follows that $M_1' = M_1$ (since $J(M_1) \cap J(\infty, B)$ is a primary ideal [21, Th. 1.2.]).

Repeating this argument for $J(\infty, B) \otimes J(M_2) \cap J(\infty, C)$ we get that $M_2 = M_2'$ and therefore that $I_0$ is primary.

[21] has transferred Ditkin's condition, condition (D) to the non-commutative case. Here we shall consider the following version.

**Definition 4.8.** A Banach algebra $B$ satisfies condition (D) if for every $M \in RS(\tilde{B})$ ($M$ may be all of $B$) $\exists$ bounded net $\{h_n\} \subset J(M) \cap J(\infty)$ such that for every $f \in (J(M) \cap J(\infty))^-$ $\exists$ subnet $\{h'_n\}$ such that $fh'_n \rightarrow f$.

**Lemma 4.9.** Let $B$ and $C$ be strongly semi-simple completely regular Banach algebras, and suppose $\tilde{T}$ is bijective. If $B$ and $C$ satisfy condition (D), then so does $B \otimes \mathcal{C}$.

**Proof.** First, let $M \in RS(B \otimes \mathcal{C}), M = \tilde{T}(M_1, M_2)$. By assumption $\exists$ bounded nets $\{h_{M_i}\} \subset J(M_i) \cap J(\infty)$ so that for every $x_i \in J(M_i) \cap J(\infty)$ $\exists$ subnet $\{h'_{M_i}\}$ for which $x_ih'_{M_i} \rightarrow x_i$ $(i = 1, 2)$. Moreover, $\exists$ bounded
nets \( \{h_{x1}\} \subset J(\infty, B), \{h_{x2}\} \subset J(\infty, C) \) so that \( xh_{x1} \rightarrow x \) for every \( x \in J(\infty, B) \) or \( J(\infty, C) \) (where \( \{h_{x1}\} \) is a subnet of \( \{h_{x}\}\)). The net we shall use in \( B \otimes C \) is \( \{k_{i} \otimes k_{i}\} \) where \( k_{i} \) is defined as follows.

\[
k_{1} \in \{h_{x1}\} \Rightarrow k_{2} \in \{h_{x2}\} \quad \text{or} \quad \{h_{x2}\}\]  
\[
k_{1} \in \{h_{x}\} \Rightarrow k_{2} \in \{h_{x}\} .
\]

It is not difficult to see that \( \{k_{1} \otimes k_{2}\} \subset J(M) \cap J(\infty, B \otimes C) \). Because \( \{k_{1} \otimes k_{2}\} \) is uniformly bounded and because of Lemma 4.7 it suffices to consider elements of the form \( x \otimes y \) with, say, \( x \in J(M_{i}) \cap J(\infty, B) \) and \( y \in J(\infty, C) \). Corresponding to this element we pick the appropriate subnets \( \{h_{x1}'\} \subset \{h_{x1}\}, \{h_{x2}'\} \subset \{h_{x2}\} \) and see immediately that

\[
(x \otimes y)(h_{x1}' \otimes h_{x2}') = xh_{x1}' \otimes yh_{x2}' \rightarrow x \otimes y .
\]

A slight variation of this argument will handle the case \( M = B \otimes C \).

We are now ready to state the strongest result concerning spectral synthesis that we know of in this context. Being essentially an application of Corollary 2.6.1 in [21] we shall simply state it as

**Corollary 4.10.** Let \( G \) be a locally compact group and \( A \) a Banach algebra so that \( L'(G) \) and \( A \) are strongly semi-simple, completely regular and satisfy condition (D). Assume further that \( L'(G, A) \) is an \( N^* \)-algebra, and that \( \bar{T} \) is bijective. Let \( I \) be a closed 2-sided ideal in \( L'(G, A) \). If the boundary of \( h(I) \) in \( RS(L'(G, A)) \) contains no perfect set (\( \not\subset \emptyset \)), then \( I = k(h(I)) \).

**Proof.** By Theorem 2.6, Theorem 2.8 and Lemma 4.9 \( L'(G, A) \) fulfils the hypotheses in Corollary 2.6.1 of [21]. Therefore the conclusion follows.

5. Concluding remarks. A comparison between this paper and [9] or [8] will quickly reveal some similarities. Both of these papers, however, deal with commutative algebras exclusively. While [8] has served as a starting point for the investigations of §3, [9] was unknown to the author at the time §2 was being developed.
