BERGMAN KERNEL FUNCTIONS AND THE THREE TYPES OF CANONICAL DOMAINS

Shozo Matsuura
BERGMAN KERNEL FUNCTIONS AND THE THREE TYPES OF CANONICAL DOMAINS

SHOZO MATSUURA

The objects of this paper are to extend J. Mitchell's theorems on minimal domains of moment of inertia for sufficiently wider class $\mathcal{F}$ and to discuss the relations among the three types of canonical domains in the $\mathcal{F}$-equivalent class. Some of the results are that, (i) a domain $D$ is the minimal domain of moment of inertia of the $[0, I_n; 0]$-equivalent class if and only if the following holds:

$$M_D^{0I}(Z, 0) = Z \text{ for } Z \in D,$$

where $M_D^{0I}(Z, 0)$ is the minimizing function of the $(0, I_n; 0)_D$-class, and (ii) if $A$, $B$ and $C$ are the sets of Bergman's minimal domains, Bergman's representative domains and Mitchell's minimal domains of moment of inertia with the same center in the $\mathcal{F}$-equivalent class respectively, and if any one of the three relations $A \cap B \neq \emptyset$, $A \cap C \neq \emptyset$ and $B \cap C \neq \emptyset$ holds, then it follows that $A \supseteq B = C$.

J. Mitchell [5] has recently proved the theorems of minimal moment of inertia for complete circular domains in the space $C^n$. In our paper [10] we have extended them for bounded Bergman's minimal domains by making use of the Bergman kernel function. But there are two restrictions which can be removed. One of them is that the transformations $W = F(Z)$ considered must belong to the class $\mathcal{F}_0$ (the set of holomorphic mappings which preserve the volume of the initial domain), and another is that the domains considered must be Bergman's minimal domains.

In § 4 of this paper we shall remove these two restrictions and extend the theorems of minimal moment of inertia for wider class $\mathcal{F}$ of transformations without volume preserving property.

In the case of several complex variables, the analogue of Riemann's mapping theorem does not hold even for simply connected domains. As the canonical domain corresponding to the unit circle in Riemann's mapping theorem, the representative domain is introduced by S. Bergman. Another object of this paper is to discuss the relations among the three types of canonical domains, i.e., Bergman's minimal domains, Bergman's representative domains and the minimal domains of moment of inertia (abbreviated as the moment minimal domains) in wider class $\mathcal{F}$ [§ 3, § 4].

The main results are Theorem 5 in § 3 and Theorems 10 and 12 in § 4.
Our theorems obtained in this paper can be extended to the cases of $m$-minimal domains, $m$-representative domains [3], [4], [10] and $m$-moment minimal domains [10] ($m \geq 1$). Therefore, for simplicity, we treat the case of $m = 1$, which is our case.

In §'s 1, 2 and 3 we treat minimal, representative and moment minimal domains and the relations among them under the restricted initial conditions of transformations. In § 4 we shall discuss the three types of canonical domains mentioned above under the extended class $\mathcal{F}$ and in particular, we attach importance to the moment minimal problem.

1. Preliminaries. In various extremal problems, mapping functions which may be meromorphic or many-valued can be successfully used. In order to treat such problems, we must extend the concept of a domain and its Bergman kernel function.

We assume that each domain with which we deal is a generalized domain (which is called a “domain” hereafter) in $\mathbb{C}^n$ following M. Maschler [3, p. 503], [4, pp. 765–770], which can be mapped holomorphically onto a bounded univalent domain in $\mathbb{C}^n$. By a holomorphic mapping (or holomorphic vector function) of a domain $D$ onto a domain $\mathcal{A}$ we mean a one-to-one mapping which, except in a denumerable number of analytic segments of manifolds of complex dimensions $\leq n - 1$, can be described locally in the column vector

\[
W = W(Z) \equiv (w_1(Z), w_2(Z), \ldots, w_n(Z)')
\]

where $w_i(Z)(i = 1, 2, \ldots, n)$ are holomorphic scalar functions of $Z \equiv (z_1, z_2, \ldots, z_n)' \in D$ with a nonvanishing Jacobian. But, in accordance with the remarks of M. Maschler [3], [4], we allow $w_i(Z)$ ($i = 1, 2, \ldots, n$) to be multi-valued meromorphic functions provided that the Jacobian $\det(dW(Z)/dZ)$ is a single-valued meromorphic function and does not vanish identically in $D$. In such a case we identify in the image domain $\mathcal{A}$ the points which correspond to the same point of $D$.

Hereafter, we shall use, except for Greek letters, upper-case letters for vectors and matrices and lower-case letters for scalars.

It is known that such domains $D$ and $\mathcal{A}$ possess Bergman kernel functions $k_d(Z, \bar{X})$, $Z, X \in D$ and $k_s(W, \bar{Y})$, $W, Y = W(X) \in \mathcal{A}$, and the relation

\[
k_d(Z, \bar{X}) = k_s(W, \bar{Y}) \det \frac{dW(Z)}{dZ} \det \frac{dW(X)}{dX}
\]

holds. $k_d(Z, \bar{X})$ is holomorphic with respect to $Z$ and $\bar{X}$, and belongs to $\mathcal{L}^2(D)$ which is a class of single-valued holomorphic
scalar functions $f(Z)$ square integrable in the sense of Lebesgue in $D$, namely

$$(3) \quad (f, f)_D = \int_D |f(Z)|^2 dv_Z < +\infty ,$$

where $dv_Z$ is the Euclidean volume element of the $Z$-space. If $D$ is a bounded domain, then $k_D(Z, \bar{Z}) > 0$, $Z \in D$, holds.

We first define the differentiation of matrix functions with respect to vector variables. Let $F(Z)$ be a matrix function

$$F(Z) = \begin{pmatrix} f_{11}(Z) \cdots f_{1m}(Z) \\ \vdots \\ f_{i1}(Z) \cdots f_{im}(Z) \end{pmatrix},$$

where $f_{ij}(Z)$ $(i = 1, 2, \ldots, l; j = 1, 2, \ldots, m)$ are scalar differentiable functions of $Z \equiv (z_1, z_2, \ldots, z_n)'$, and $d/dZ$ is the differential operator of row vector type:

$$(4) \quad \frac{d}{dZ} \equiv \left( \frac{\partial}{\partial z_1}, \frac{\partial}{\partial z_2}, \ldots, \frac{\partial}{\partial z_n} \right).$$

We define the differentiation as follows:

$$(5) \quad \frac{d}{dZ} F(Z) \equiv \frac{d}{dZ} \times F(Z).$$

Here the Kronecker product of two matrices $A$ and $B = (b_{ij})$ (notation: $A \times B$) denotes

$$A \times B = \begin{pmatrix} Ab_{11} & Ab_{12} & \cdots \\ Ab_{21} & Ab_{22} & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix},$$

where $A$ may be an operator of matrix type.

For convenience, we note here some differential formulas. Let the functions $A$, $B$ and $b$ of $Z \equiv (z_1, z_2, \ldots, z_n)'$ be $(k \times l)$, $(l \times m)$ matrices and a scalar, respectively. The following formulas can be easily calculated:

$$(6) \quad \frac{d}{dZ} AB = \frac{dA}{dZ} (I_n \times B) + A \frac{dB}{dZ},$$

$$\frac{dA}{dZ} = \frac{dA}{dW} \left( \frac{dW}{dZ} \times I_l \right), \quad A = A(W),$$

$$W \equiv (w_1(Z), w_2(Z), \ldots, w_n(Z))'.$
where $I_k$ denotes an identity matrix of order $k$ ($k$: positive integer).

Next we define the transposed conjugate differential operator $d/dZ^*$ as follows:

$$
\frac{d}{dZ^*}A(\bar{Z}) \equiv \frac{d}{dZ^*} \times A(\bar{Z}) \equiv \left(\frac{\partial}{\partial \bar{z}_1}, \frac{\partial}{\partial \bar{z}_2}, \ldots, \frac{\partial}{\partial \bar{z}_n}\right)' \times A(\bar{Z}).
$$

Throughout this paper, vectors and matrices marked with the symbol ' or * denote the transposed or transposed conjugate vectors and matrices, respectively.

Let us put

$$
T_D(Z, \bar{Z}) = \int_{\Sigma} d\bar{L}^* \log k_D(Z, X), Z, X \in D,
$$

then $ds^2 = dZ^* T_D(Z, \bar{Z}) d\bar{Z}$ is a Kähler metric of $D$ and $T_D(Z, \bar{Z})$ is positive definite. The quantities $k_D(Z, X)$ and $T_D(Z, \bar{Z})$ play important roles in this paper.

2. Bergman's minimum problems.

**DEFINITION 1.** (i) $(X_o, X_i; P)_D$-class denotes the class of holomorphic vector functions

$$
W(Z) = (w_1(Z), w_2(Z), \ldots, w_n(Z))'
$$
in a domain $D$ in the $Z \equiv (z_1, z_2, \ldots, z_n)'$-space which satisfy, at a non-branch point $P = (p_1, p_2, \ldots, p_n)' \in D$, the following initial conditions:

$$
W(P) = X_o, \quad \frac{dW(P)}{dZ} = X_1, \quad \text{det} \ X_1 \neq 0,
$$

where $X_o, X_i$ are $(n \times 1), (n \times n)$ constant matrices, respectively. And the class of image domains by the mappings belonging to the $(X_o, X_i; P)_D$-class is called the $[X_o, X_i; P]^p$-equivalent class.

(ii) $(x_i; P)_D$-class denotes the class of holomorphic vector functions $W(Z)$ on $D$, which satisfy the following conditions:

$$
W(P) = 0, \quad \text{det} \ \frac{dW(P)}{dZ} = x_i \neq 0,
$$

where $x_i$ is a scalar constant. The equivalent class of image domains of $D$ obtained by the mappings $W(Z)$ belonging to the $(x_i; P)_D$-class is called the $[x_i; P]^p$-equivalent class.
Remark 1. Because $X_0$ denotes a parallel transformation and has no influence upon the situation of our theory, we will assume hereafter that $X_0 = 0$ without loss of generality. The $(1; P)_D$-class contains the $(0, I_n; P)_D$-class, and therefore the $[0, I_n; P]_D^*$-equivalent class is a subclass of the $[1; P]_D^*$-equivalent class.

Theorem 1. (i) There exists the unique function belonging to the $(0, X_1; P)_D$-class which minimizes the integral

$$\int_D |F(Z)|^2 dv_Z = \int_D F^*(Z)F(Z)dv_Z,$$

where $F(Z) \in (0, X_1; P)_D$-class and $dv_Z$ denotes the Euclidean volume element of the $Z$-space.

Let $M_{D}^{0,X_1}(Z, P)$ be the minimizing function for (13) and $\lambda_{D}^{0,X_1}(P)$ the minimum value of (13) for $M_{D}^{0,X_1}(Z, P)$, where $P$ is not on a branch manifold on $D$. Writing them as matrices, we have

$$M_{D}^{0,X_1}(Z, P) = (0, X_1)(H_D(P, \bar{P}))^{-1}L_D(Z, \bar{P}),$$

and

$$\lambda_{D}^{0,X_1}(P) = \text{Spur} [(0, X_1)(H_D(P, \bar{P}))^{-1}(0, X_1)^*],$$

where

$$H_D(P, \bar{P}) = \begin{pmatrix} k_{00}^* & k_{10}^* \\ k_{01}^* & k_{11}^* \end{pmatrix},$$

$$L_D(Z, \bar{P}) = \begin{pmatrix} k_D(Z, \bar{P}) \\ k_{0*}(Z, \bar{P}) \end{pmatrix},$$

and

$$k_{i*,*}(Z, \bar{X}) = \frac{\partial^{i+j}}{\partial Z^i \partial \bar{X}_{*j}} k_D(Z, \bar{X}),$$

$$k_{i*,*} = k_{i*,*}(P, \bar{P}), \quad k_{00}^* = k_D(P, \bar{P}).$$

(ii) For the $(x_1; P)_D$-class, the minimizing function $W(Z)$ which minimizes the integral

$$\int_D \left| \det \frac{dF(Z)}{dZ} \right|^2 dv_Z, \quad F(Z) \in (x_1; P)_D \text{-class},$$

satisfies

$$\det \frac{dW(Z)}{dZ} = m_{ij}^*(Z, P) = x_i k_{00}^{-1} k_D(Z, \bar{P})$$
and the minimum value of (20) for (21) is

\[ \lambda_{yi}^{ij}(P) = x_i k_{y_i}^{ij} = \frac{|x_i|^2}{k_{00}^*}. \]

This theorem has been proved in [6] and our paper [10] for more general initial conditions. Therefore, we omit the proof of this theorem.

\( m_{ij}^b(Z, P) \) in (21) is the special case of (14) for the class of scalar functions \( f(Z) \) with the initial condition \( f(P) = x_i \).

The minimizing functions \( M_{ij}^{y_j x_j}(Z, P) \), \( m_{ij}^b(Z, P) \) are relative invariant under any holomorphic mapping \( W(Z)(\det (dw(P))/dz \neq 0) \) [3; p. 503], [4; pp. 765-770]; that is, putting \( \Delta = W(D), \)

\[ M_{ij}^{y_j x_j}(Z, P) = M_{ji}^{y_j x_j}(W(Z), W(P)) \det \frac{dW(Z)}{dZ}, \]

\[ m_{ij}^b(Z, P) = m_{ji}^b(W(Z), W(P)) \det \frac{dW(Z)}{dZ}, \]

where \( Y_\nu (\nu = 0, 1) \) and \( y_\nu \) are determined for the function \( G(W) \) such that \( G(W(Z)) \det (dW(Z)/dz) \) belongs to the \((X_\nu, X_1; P)_D\)-class by the system of equations

\[ \frac{d^\nu}{dZ^\nu} \left( G(W(Z)) \det \frac{dW(Z)}{dz} \right) \bigg|_{Z = P} = X_\nu (\nu = 0, 1), \]

\[ G^{(\nu)}(Q) = Y_\nu (\nu = 0, 1), \quad Q = W(P), \]

and

\[ x_i = y_i \det \frac{dW(P)}{dz} \]

and \( P \) is not on a branch manifold.

The system (25) has one and only one solution, because \( \det (dW(P)/dz) \neq 0 \).

These minimum problems were treated originally by S. Bergman [1].

3. Minimal domains, representative domains and moment minimal domains.

DEFINITION 2. Let \( W = W(Z) = (w_1(Z), w_2(Z), \ldots, w_n(Z))' \) be a holomorphic mapping of \( D \) in \( C^n \) belonging to the \((1; P)_D\)-class and making (20) a minimum. The image domain \( \Delta_y \) of \( D \) under \( W(Z) \) is called a (Bergman) minimal domain of \([1; P]^D\)-equivalent class with center at \( W(P) = 0 \) and \( W(Z) \) a minimal function.
The next theorem is well known [4], [10].

**THEOREM 2.** (i) If $W(Z)$ is a minimal function, then

\[
\det \frac{dW(Z)}{dZ} = m_D^1(Z, P) = \frac{k_D(Z, \bar{P})}{k_D(P, \bar{P})} \in \mathcal{L}^1(D).
\]

(ii) A domain $D$ is a minimal domain of the $[1; P]$-equivalent class with center at $P \in D$ if and only if

\[
m_D^1(Z, P) = 1 \quad \text{for} \quad Z \in D,
\]

that is,

\[
k_D(Z, \bar{P}) = k_D(P, \bar{P}) \quad \text{for} \quad Z \in D.
\]

(iii) A minimal domain $D$ with center at $P$ is characterized by the following property: Any holomorphic mapping $F(Z)$ belonging to the $(1; P)_D$-class maps $D$ onto a domain whose volume is not less than the volume of $D$.

**REMARK 2.** A minimal function which minimizes the integral (20) is not uniquely determined. One of the minimal functions belonging to the $(0, I_n; P)_D$-class ($\subset (1; P)_D$-class) is, for instance, given by

\[
W(Z) = \begin{pmatrix}
    w_1(Z) \\
    w_2(Z) \\
    \vdots \\
    w_n(Z)
\end{pmatrix} = \begin{pmatrix}
    \int_{p_1}^{z_1} m_D(t, z_2, \cdots, z_n; P) dt + f(z_2, \cdots, z_n) \\
    z_{2-p_2} \\
    \vdots \\
    z_{n-p_n}
\end{pmatrix},
\]

where $f(z_2, \cdots, z_n)$ is an arbitrary holomorphic scalar function of $(z_2, \cdots, z_n)$ and is equal to 0 at $Z = P = (p_1, p_2, \cdots, p_n)'$ [5, p. 230].

**THEOREM 3.** The function

\[
W_D(Z, P) = \frac{M_D^1(Z, P)}{m_D^1(Z, P)} \in (0, I_n; P)_D\text{-class}
\]

is absolutely invariant under any mapping belonging to the $(0, I_n; P)_D$-class.

**Proof.** This theorem is easily obtained by (23), (24). If $X_0 = (0, \cdots, 0)' = 0$, $X_1 = I_n$, then we have $Y_0 = 0$ and $Y_1 = I_n$ for any $F(Z) \in (0, I_n; P)_D$-class by direct calculations (using (6), (7) and (8)).

**DEFINITION 3.** The image domain $\Delta_w = W_D(D, P)$ is called the (Bergman) representative domain of the $[0, I_n; P]^D$-equivalent class
with center at the origin, and $W_D(Z, P)$ the representative function.

The next theorem is known [8], [9].

**Theorem 4.** (i) A domain $D$ is a representative domain with center at $P$ if and only if

$$\frac{M_{D}^{'}(Z, P)}{m_{D}^{'}(Z, P)} = Z - P, \quad Z \in D,$$

that is,

$$T_D(Z, \bar{P}) = T_D(P, \bar{P}), \quad Z \in D.$$

(ii) A domain $D$ is a minimal and also a representative domain with the same center at $P$ if and only if

$$M_{D}^{''}(Z, P) = Z - P \quad \text{and} \quad m_{D}^{''}(Z, P) = 1, \quad Z \in D,$$

that is,

$$k_{m}(Z, \bar{P}) = k_{m}(P, \bar{P}) \quad \text{and} \quad k_{D}(Z, \bar{P}) = k_{D}(P, \bar{P}), \quad Z \in D.$$

In the above, $P$ denotes a parallel transformation of $D$. Therefore we may take $P = 0$, without loss of generality. We shall take $P = 0$ hereafter.

**Definition 4.** The minimizing function $W(Z) \in (0, I_n; 0)_{D}$-class which minimizes the integral

$$I = \int_{D} F^{*}(Z)F(Z) d\nu_F,$$

where $F(Z) \in (0, I_n; 0)_{D}$-class and $\Delta = F(D)$, is called the minimal function of moment of inertia (denoted as the moment minimal function of the $(0, I_n; 0)_{D}$-class), and the image domain $\Delta_w = W(D)$ the moment minimal domain of the $[0, I_n; 0]^{p}$-equivalent class with center at the origin.

**Theorem 5.** (i) The moment minimal function $W(Z)$ of the $(0, I_n; 0)_{D}$-class, if it exists satisfies

$$W(Z) \det \frac{dW(Z)}{dZ} = M_{D}^{''}(Z, 0).$$

The holomorphic function $W(Z)$ which satisfies (35), if it exists, is determined uniquely by the initial condition that $W(Z)$ belongs to the $(0, I_n; 0)_{D}$-class.

(ii) A domain $D$ is the moment minimal domain of the $[0, I_n; 0]^{p}$-equivalent class if and only if
(36) \( M^{d^*}_{D}(Z, 0) = Z \) for \( Z \in D \),

that is, by the notation of (10)

\[
(37) \quad T_D(0, 0) = \frac{k_{00}^* k_{11}^*(Z, 0) - k_{01}^* k_{10}^*(Z, 0)}{k_{00}^*}, \quad Z \in D,
\]

where \( k_{00}^* = k_D(0, 0) \).

Proof. (i) For a function \( F(Z) \in (0, I_n; 0) \)-class,

\[
I = \int_D F^*(Z) F(Z) \, dv_F = \int_D F^*(Z) F(Z) \left| \det \frac{dF(Z)}{dZ} \right|^2 \, dv_Z,
\]

where \( \Delta = F(D) \). It is clear that \( F(Z) \det (dF(Z)/dZ) \) belongs to the \( (0, I_n; 0) \)-class, thus by Theorem 1 the minimizing function \( W(Z) \), if it exists, satisfies (35).

Conversely, if \( W(Z) \) satisfies (35), then for an arbitrary function \( F(Z) \in (0, I_n; 0) \)-class, we have

\[
\int_{F(D)} F^*(Z) F(Z) \, dv_F = \int_D F^*(Z) F(Z) \left| \det \frac{dF(Z)}{dZ} \right|^2 \, dv_Z
\]

\[
= \int_D \left| F(Z) \det \frac{dF(Z)}{dZ} \right|^2 \, dv_Z \geq \int_D |M^d_{D^*}(Z, 0)|^2 \, dv_Z
\]

\[
= \int_D W(Z) \det \frac{dW(Z)}{dZ} \left| W(Z) \right|^2 \, dv_Z = \int_{W(D)} W(Z) \, dv_w.
\]

This shows that \( W(Z) \) is a moment minimal function belonging to the \( (0, I_n; 0) \)-class.

Now we shall prove the uniqueness of the moment minimal function which satisfies (35). For simplicity, without loss of generality, we treat the case of \( W(Z) = (u(Z), v(Z))' \), \( Z = (x, y)' \).

Suppose that there exists the unique function \( W = W(Z) \), which satisfies (35) and belongs to the \( (0, I_z; 0) \)-class, on the representative domain \( D \), and let the function \( Z = Z(Z^0) \) be the representative function (uniquely determined by Theorem 3) which maps \( D \) (an arbitrary domain belonging to the \([0, I_z; 0]\)-equivalent class) onto the representative domain \( D \), then we have

\[
W(Z) \det \frac{dW(Z)}{dZ} = W(Z(Z^0)) \det \frac{dW(Z(Z^0))}{dZ^0} \det \frac{dZ^0}{dZ}.
\]

On the other hand, by (23) we have

\[
M^d_{D^*z}(Z, 0) = M^d_{D^*z}(Z^0, 0) \det \frac{dZ^0}{dZ}.
\]

Thus from (35) we obtain the unique function \( W(Z(Z^0)) \equiv W^0(Z^0) \)
This shows that in (35) we may assume a domain \( D \) to be the representative domain with center at origin, without loss of generality.

Now, on the representative domain \( D \) we have
\[
M_{D, z}^2(0, 0) = Z m_{D}(Z, 0) = (x m_{D}(Z, 0), y m_{D}(Z, 0))
\]
by Theorem 4. Thus, in place of (35), we have
\[
(38) \quad u(Z) \det \frac{dW(Z)}{dZ} = x m_{D}(Z, 0), \quad v(Z) \det \frac{dW(Z)}{dZ} = y m_{D}(Z, 0).
\]
As \( W(0) = 0 \) and \( dW(0)/dZ = I_z \), in the neighborhood of the origin we see that
\[
(39) \quad u(Z) = x \bar{u}(Z), \quad \bar{u}(0) = 1; \quad v(Z) = y \bar{v}(Z), \quad \bar{v}(0) = 1;
\]
and from (38) and (39) we have
\[
(40) \quad \bar{u}(Z) = \bar{v}(Z).
\]
From (38) and (40), we obtain
\[
(41) \quad \bar{u}(Z) \left( \bar{u}(Z) + x \frac{\partial}{\partial x} \bar{u}(Z) + y \frac{\partial}{\partial y} \bar{u}(Z) \right) = m_{D}(Z, 0).
\]
We may assume that
\[
(42) \quad m_{D}(Z, 0) = 1 + \sum_{\alpha + \beta \geq 1} c_{\alpha \beta} x^\alpha y^\beta,
\]
\[
(43) \quad \bar{u}(Z) = 1 + \sum_{\alpha + \beta \geq 1} a_{\alpha \beta} x^\alpha y^\beta,
\]
where \( a_{\alpha \beta}(\alpha + \beta \leq 1) \) are given coefficients and \( a_{\alpha \beta}(\alpha + \beta \geq 1) \) have to be determined. Substituting (42) and (43) into (41), we have
\[
\left(1 + \sum_{\alpha + \beta \geq 1} a_{\alpha \beta} x^\alpha y^\beta \right)^2 \left(1 + \sum_{\alpha + \beta \geq 1} (\alpha + \beta + 1) a_{\alpha \beta} x^\alpha y^\beta \right) = 1 + \sum_{\alpha + \beta \geq 1} c_{\alpha \beta} x^\alpha y^\beta.
\]
In comparing the coefficients of \( x^\alpha y^\beta \) on both sides, we obtain
\[
a_{10} = \frac{c_{10}}{4}, \quad a_{01} = \frac{c_{01}}{4}, \quad a_{20} = \frac{c_{20}}{5} - a_{10} = \frac{c_{20}}{5} - \frac{1}{16} c_{10}^2,
\]
\[
a_{11} = \frac{1}{5} \left( c_{11} - \frac{5}{8} c_{10} c_{01} \right), \quad a_{02} = \frac{c_{02}}{5} - \frac{1}{16} c_{01}^2, \text{ etc.}
\]
Generally, as each \( a_{\alpha \beta} \) is a polynomial in \( c_{\alpha \beta} \) and \( a_{ij} \) (\( i + j < \alpha + \beta \)),
We can thus determine $a_\alpha \beta (\alpha + \beta \geq 1)$ uniquely by recurrence.

If $W(Z)$ exists in the neighborhood of the origin, by the method of analytic continuation we can obtain the unique holomorphic solution of (35) on $D$ except in a denumerable number of analytic segments of manifolds of complex dimensions $\leq n - 1$.

(ii) Let $D$ be a moment minimal domain. Putting
\[ W(Z) = Z \in (0, I_n; 0)_D\text{-class}, \]
by Theorem 5 (i) we have
\[ Z = M_{D}^{0}(Z, 0) \quad \text{for} \quad Z \in D. \]
Conversely, if $Z = M_{D}^{0}(Z, 0)$ for $Z \in D$, for any $F(Z) \in (0, I_n; 0)_D\text{-class}$ we have
\[
I = \int_D Z^* Zd\nu_Z = \int_D M_{D}^{0}(Z, 0)M_{D}^{0}(Z, 0)d\nu_Z
\leq \int_D F^*(Z) \det \frac{dF(Z)}{dZ} F(Z) \det \frac{dF(Z)}{dZ} d\nu_Z
= \int_{F(D)} F^*(Z) F(Z) d\nu_F,
\]
because $F(Z) \det (dF(Z)/dZ)$ belongs to the $(0, I_n; 0)_D\text{-class}$. This shows that $D$ is a moment minimal domain.

From (ii), if $D$ is a moment minimal domain, then
\[
Z = M_{D}^{0}(Z, 0) = (0, I_n) \begin{pmatrix} k_{00*} & k_{10*} \\ k_{01*} & k_{11*} \end{pmatrix}^{-1} \begin{pmatrix} k_D(Z, 0) \\ k_{01*}(Z, 0) \end{pmatrix}
= T^{-1}_D(0, 0) \frac{k_{00*}k_{01*}(Z, 0) - k_{00*}k_D(Z, 0)}{k_{00*}^2},
\]
where $T_D(0, 0) = (k_{00*}k_{11*} - k_{01*}k_{10*})/k_{00*}^2$. Differentiating both sides of the above, we have (37). The converse is proved by integration.

**Remark 3.** At the origin the condition (37) is satisfied by an arbitrary domain, but in general it may not hold on $D$.

**Example 1.** In the case of a complex variable, (35) is reduced to
\[
w(z) \frac{dw(z)}{dz} = m_D^{0\beta}(z, 0).
\]
Integrating the above, we have
\[
\int_{0}^{w} wdw = \int_{0}^{z} m_D^{0}(z, 0)dz,
\]
consequently
\[
\frac{w^2}{2} = \frac{1}{k_{00}^* T_D(0, 0)} \int_0^z (k_{00} k_{01} (z, 0) - k_{01} k_D (z, 0)) \, dz.
\]

Thus the moment minimal function \( w = w(z) \) is a two-valued function, but from the initial condition of \( w(z) \) (belonging to the \((0, 1; 0)_D\)-class) the only one moment minimal function is determined.

If \( D \) is the unit circle, by \([1]\)
\[
k_D(z, \bar{t}) = \frac{1}{\pi (1 - z\bar{t})^2}.
\]

By simple calculations we have
\[
k_D(z, 0) = \frac{1}{\pi} = k_{00}^*,
\]
\[
k_{01}(z, 0) = -\frac{2}{\pi} z,
\]
\[
k_{01}(0, 0) = 0,
\]
\[
T_D(0, 0) = \frac{k_{11}}{k_{00}^*} = \pi \left( -\frac{2}{\pi} \right) = -2,
\]

and hence
\[
\int_0^z m_D^{\bar{1}}(z, 0) \, dz = -\frac{\pi^2}{2} \int_0^z \frac{1}{\pi} \left( -\frac{2}{\pi} z \right) \, dz = \int_0^z zdz.
\]

Therefore the unit circle is the moment minimal domain of the \([0, 1; 0]_D\)-equivalent class with center at the origin, and the moment minimal function is
\[
\frac{w^2}{2} = \frac{z^2}{2}, \text{ i.e., } w = z \in (0, 1; 0)_D\text{-class}.
\]

Thus for the unit circle the identity mapping is the only one moment minimal function belonging to the \((0, 1; 0)_D\)-class. Further the unit circle is an example of a minimal and also a representative domain with the same center at the origin from (28) and (31).

**Theorem 6.** If \( D \) is (a) a minimal and also (b) a representative domain with the same center at the origin, then \( D \) is (c) a moment minimal domain with the same center.

In this theorem, we may exchange (a) or (b) for (c), respectively.

**Proof.** By Theorem 2, Theorem 4, and Theorem 5, necessary and sufficient conditions for (a), (b) and (c) are
\[ m'_2(Z, 0) = 1, \quad \frac{M'^n_D(Z, 0)}{m'_2(Z, 0)} = Z \quad \text{and} \quad M'^n_D(Z, 0) = Z \quad \text{for} \quad Z \in D, \]

respectively. Therefore, any two of the above conditions are sufficient conditions for the remainder.

It is known that there exists a minimal but not representative domain with the same center, or a representative but not minimal domain with the same center [3], [4].

Example of minimal and also representative domains with the same center at the origin are Cartan irreducible symmetric domains or more generally bounded complete Carathéodory circular domains. Furthermore, they are simultaneously moment minimal domains with the same center [3], [10].

4. Extended class. Let us consider the \((0, X_1; 0)_D\)-class, where \(X_1\) is an arbitrary constant \((n \times n)\) matrix satisfying \(\det X_1 \neq 0\).

**Lemma 1.** The \([0, X_1; 0]_D\)-equivalent class is equal to the \([0, I_n; 0]_A\)-equivalent class, where \(A = F(D), F(Z) \in (0, X_1; 0)_D\)-class.

**Proof.** Let \(W_1(Z), W_2(Z)\) belong to the \((0, X_1; 0)_D\)-class, and \(A_{w_1}, A_{w_2}\) be the images of \(D\) by the mappings \(W_1(Z), W_2(Z)\), respectively. We may assume the existence of the mapping \(\eta(W_1(Z)) = W_2(Z)\) which maps \(A_{w_1}\) onto \(A_{w_2}\). Because from the hypothesis on domains, it may be assumed that \(D\) is a bounded univalent domain and the existence of an inverse holomorphic mapping \(Z = Z(W_1)\) in the neighborhood of \(W_1 = 0\) follows from \(\det (dW_1(Z)/dZ)|_{Z=0} = \det X_1 \neq 0\). Then we can define a function \(Z = Z(W_1)\) on \(A_{w_1}\) by the method of analytic continuation. Put \(\eta = \eta(W_1) = W_2(Z(W_1))\), then we have a desired holomorphic mapping \(\eta(W_1) = W_2\) on \(A_{w_1}\), which maps \(A_{w_1}\) onto \(A_{w_2}\). Since \(W_1(Z), W_2(Z)\) belong to the \((0, X_1; 0)_D\)-class, we have

\[ \eta(W_1(0)) = \eta(0) = W_2(0) = 0. \]

Differentiating both sides of \(\eta(W_1(Z)) = W_2(Z)\) with respect to \(Z\) and putting \(Z = 0\) yields that

\[ \frac{d\eta(W_1)}{d W_1}_{W_1=0} \bigg|_{Z=0} \frac{dW_1(Z)}{dZ} \bigg|_{Z=0} = \frac{dW_2(Z)}{dZ} \bigg|_{Z=0}, \]

that is,

\[ \frac{d\eta(0)}{d W_1} X_1 = X_1. \]
Thus we have
\[ \frac{d\gamma(0)}{dW_1} = I_n. \]

From the above, we see that \( \gamma = \gamma(W) \) belongs to the \((0, I_n; 0)_{D_1}\)-class. Thus we have the following:

**Theorem 7.** The image domain \( \Delta \) of \( D \) under the mapping

\[ W = X_1 \frac{M_D^0(Z, 0)}{m_D(Z, 0)} \in (0, X_1; 0)_D \text{-class} \]

is the representative domain of the \((0, I_n; 0)_D\)-equivalent class with center at the origin. Thus we call (44) the representative function of the \((0, X_1; 0)_D\)-class and \( \Delta = W(D) \) the representative domain of the \([0, X_1; 0] D\)-equivalent class.

**Proof.** It is clear from Lemma 1 that \( W(Z) \) belongs to the \((0, X_1; 0)_D\)-class. By the holomorphic invariance of minimizing functions (see (23), (24)) we have

\[ W(Z) = X_1 \frac{M_D^0(Z, 0)}{m_D(Z, 0)} = X_1 \frac{M_d^0(W, 0)}{m_d(W, 0)} \det \frac{dW}{dZ} = X_1 \frac{M_d^0(W, 0)}{m_d(W, 0)} \cdot \]

Differentiating both sides of

\[ M_D^0(Z, 0) = M_d^0(W, 0) \det \frac{dW}{dZ} \]

with respect to \( Z \), and putting \( Z = 0 \), we have

\[ \frac{d}{dZ} M_D^0(0, 0) = I_n = \frac{d}{dW} M_d^0(0, 0) \frac{dW(0)}{dZ} \det \frac{dW(0)}{dZ} \]
\[ + M_d^0(0, 0) \frac{d}{dZ} \det \frac{dW(0)}{dZ} = Y_1 X_1 \det X_1, \]

and thus

\[ Y_1 = X_1^{-1} / \det X_1. \]

For

\[ m_D(Z, 0) = m_d(W, 0) \det \frac{dW}{dZ} \]

we have
\[ y_1 = 1/\det X_1 \]
as well as the above. Hence we obtain
\[ W = X_1 \frac{M_2^{0,1}(W, 0)}{m_2^1(W, 0)} = X_1 \frac{Y_1 M_2^{0,1}(W, 0)}{y_1 m_2^1(W, 0)} = \frac{M_2^{0,1}(W, 0)}{m_2^1(W, 0)} . \]
Recalling Theorem 4, this shows that the domain \( \Delta = W(D) \) is the representative domain of the \([0, I_n; 0]^t\)-equivalent class.

**Corollary 1.** The unique mapping function \( W = W(Z) \) which maps the representative domain \( D \) of the \([0, I_n; 0]^p\)-equivalent class onto the representative domain \( \Delta \) of the \([0, X_1; 0]^p\)-equivalent class (the \([0, I_n; 0]^t\)-equivalent class) with the same center at the origin, where \( W(D) = \Delta \), is
\[ W = X_1 Z . \]

**Proof.** If \( D \) is the representative domain of \([0, I_n; 0]^p\)-equivalent class, then
\[ \frac{M_D^{0,1}(Z, 0)}{m_D^1(Z, 0)} = Z \quad \text{for} \quad Z \in D . \]
Thus by Theorem 7 we have the result.

**Theorem 8.** If \( F(Z) \) belongs to the \((x_i; 0)_D\)-class normalized by \( F(0) = 0 \) and \( |x_1| = 1 \), then the \([x_i; 0]^p\)-equivalent class becomes the \([1; 0]^t\)-equivalent class, where \( F(D) = \Delta \). The image domain \( \Delta = W(D) \) by a mapping such that
\[ \det \frac{dW(Z)}{dZ} = x_1 m_1^1(Z, 0) \quad \text{for} \quad Z \in D \]
is a minimal domain of the \([1; 0]^t\)-equivalent class with center at the origin. Hence we shall call \( W(Z) \) a minimal function of the \([x_i; 0]^p\)-equivalent class with center at the origin.

**Proof.** For arbitrary two functions \( \xi = F(Z) \) and \( \eta = G(Z) \) belonging to the \((x_i; 0)_D\)-class normalized by \( |x_1| = 1 \), we have the relation
\[ G(Z) = \eta(\xi) = \eta(F(Z)) . \]
Differentiating both sides of the above with respect to \( Z \), we have
\[ dG(Z)/dZ = (d\eta/d\xi)(dF(Z)/dZ) \] and so
\[
\det \frac{dG(Z)}{dZ} = \det \frac{d\eta}{d\xi} \det \frac{dF(Z)}{dZ}.
\]

Since \( \det (dG(0)/dZ) = \det (dF(0)/dZ) = x_1 \), we have

\[
\det \frac{d\eta(0)}{d\xi} = 1.
\]

Thus \( \eta = \eta(\xi) \) belongs to the \([1; 0]^d\)-equivalent class, where \( \Delta = F(D) \).

By (21), (24) and (46), for a minimizing function \( W(Z) \in (x_1; 0)_D \)-class we have

\[
\det \frac{dW(Z)}{dZ} = x_1 m^1_{jw}(Z, 0) = m^1_{jw}(W, 0) \det \frac{dW}{dZ},
\]

that is,

\[
m^1_{jw}(W, 0) = 1 \quad \text{for} \quad W \in \Delta_w.
\]

This shows that \( \Delta_w \) is a minimal domain of the \([x_1; 0]^p\)-equivalent class, i.e., the \([1; 0]^d\)-equivalent class with center at the origin (by Theorem 2 and the above).

Existence of the mappings which satisfy the equation (46) is shown in Remark 2.

**Corollary 2.** The mapping function \( W(Z) \) (belonging to the \((x_1; 0)_D\)-class) which maps a minimal domain \( D \) of the \([1; 0]^p\)-equivalent class with center at the origin onto another minimal domain \( \Delta \) of the \([1; 0]^d\)-equivalent class, where \( \Delta = W(D) \), satisfies the conditions

\[
W(0) = 0, \quad \det \frac{dW(Z)}{dZ} = x_1 \quad \text{for} \quad Z \in D,
\]

and vice versa. This mapping is a volume preserving one. One such mapping, for instance, is

\[
W = X_1 Z, \quad \det X_1 = x_1.
\]

**Proof.** By (21) and (24) we have

\[
m^{x_1}_D(Z, 0) = x_1 m^{x_1}_D(Z, 0) = m^{x_1}_1(W, 0) \det \frac{dW}{dZ} = y_1 m^{x_1}_1(W, 0) \det \frac{dW}{dZ},
\]

where \( y_1 = 1 \) since \( W(Z) \) belongs to the \((x_1; 0)_D\)-class. Since \( D \) and \( \Delta \) are minimal domains of the \([1; 0]^p\)-equivalent class and the \([1; 0]^d\)-equivalent class respectively, by (27) we have \( m^{x_1}_D(Z, 0) = 1 \) for \( Z \in D \) and \( m^{x_1}_j(W, 0) = 1 \) for \( W \in \Delta \). Thus we obtain (47). The converse is
clear from (24). The volume preserving property for \( W(Z) \in (x_i; 0)_D \)-class, \( |x_1| = 1 \), is the consequence of the following:

\[
\text{vol} (\mathcal{D}) = \int_{\mathcal{D}} dv_w = \int_{\mathcal{D}} \left| \det \frac{dW}{dZ} \right| dv_Z = \int_{\mathcal{D}} |x_i|^2 dv_Z = \int_{\mathcal{D}} dv_Z = \text{vol} (D).
\]

It is clear that \( W = X_1 Z, \ det X_1 = x_i, \) satisfies (46).

Hereafter we shall use the initial condition \((0, X; 0)_D\) normalized by \(|\det X| = 1\). \( C_X \) denotes the set of \((n \times n)\) square constant matrices \( X \) such that \(|\det X| = 1\). Let us introduce the wider class

\[(49) \quad \mathcal{F} = \left\{ \mathcal{U} (0, X; 0)_D \text{-class} \mid X \in C_X \right\}.
\]

This extended class contains the \((0, I_n; 0)_D\)-class and admits a group of transformations of \( D \) with a subgroup of the \((0, I_n; 0)_D\)-class. \( \mathcal{F} \) contains \( \mathcal{F}_1 = \left\{ \mathcal{U}_{x_1} (0, X_1; 0)_D \text{-class} \mid \det X_1 = 1 \right\} \) as a subclass, too. It holds

\[(50) \quad \mathcal{F} \supset \mathcal{F}_1 \supset (0, I_n; 0)_D \text{-class},
\]

where \( \mathcal{F}_1 \) is equal to the \((1; 0)_D\)-class (see Definition 2).

**Theorem 9.** (i) All minimal domains in the \( \mathcal{F} \)-equivalent class have the same volume, which is equal to the volume of a minimal domain of the \( \mathcal{F}_1 \)-equivalent class.

(ii) All representative domains in the \( \mathcal{F} \)-equivalent class have the same volume, which is equal to the volume of the representative domain of the \([0, I_n; 0]^p\)-equivalent class.

**Proof.** (i) By Theorem 8 and Corollary 2, the mapping function \( W(Z) \) of a minimal domain \( D \) of the \( \mathcal{F}_1 \)-equivalent class onto an arbitrary minimal domain \( \mathcal{D} \) in the \( \mathcal{F} \)-equivalent class satisfies

\[
\det \frac{dW(Z)}{dZ} = \det Xm_b(Z, 0) = \det X, \quad X \in C_X.
\]

Therefore

\[
\text{vol} (\mathcal{D}) = \int_{\mathcal{D}} dv_w = \int_{\mathcal{D}} \left| \det \frac{dW(Z)}{dZ} \right| dv_Z
\]

\[
= \int_{\mathcal{D}} |\det X|^2 dv_Z = \int_{\mathcal{D}} dv_Z = \text{vol} (D).
\]

(ii) By Corollary 1, the mapping function \( W(Z) \) of the representative domain \( D \) of the \([0, I_n; 0]^p\)-equivalent class onto an arbitrary representative domain \( \mathcal{D} \) in the \( \mathcal{F} \)-equivalent class is

\[
W = XZ, \quad X \in C_X.
\]
Thus we obtain
\[ \text{vol}(D) = \int_{D} dv_w = \int_{D} \left| \det \frac{dW(Z)}{dZ} \right|^2 dv_z = \text{vol}(D). \]

**COROLLARY 3.** Let \( A, B \) and \( C \) denote the sets of minimal domains, representative domains and moment minimal domains in the \( \mathcal{F} \)-equivalent class, respectively. If \( A \cap B \neq \phi \), then \( B = A \cap C \).

(cf. Theorem 12).

**Proof.** An arbitrary domain \( D \in A \cap B \) belongs to \( C \) (by Theorem 6). By Theorem 9 (ii), \( B \subset A \) holds. Thus we have \( B \subset (A \cap C) \). On the other hand, it is clear that an arbitrary domain \( D \in A \cap C \) belongs to \( B \) (by Theorem 6). Thus we have the result.

**THEOREM 10.** Suppose in the \( \mathcal{F} \)-equivalent class no domain exists which is simultaneously a minimal and representative with respect to the same point (which can be chosen as the origin 0). Then there does not exist in that class a domain which is simultaneously a minimal and moment minimal. Further there does not exist a domain which is simultaneously a representative and moment minimal with respect to 0.

**Proof.** Let \( A, B, \) and \( C \) denote the sets mentioned in Corollary 3. By hypothesis we have \( A \cap B = \phi \). If \( A \cap C \neq \phi \) (or \( B \cap C \neq \phi \)), that is, if a domain \( D \) belongs to \( A \cap C \), then by Theorem 6, \( D \) must belong to \( B \). Thus \( A \cap B = \phi \). This is a contradiction.

**REMARK 4.** If \( A \cap C = \phi \), then \( A \cap B = \phi \) and \( B \cap C = \phi \) hold, and if \( B \cap C = \phi \), then \( A \cap B = \phi \) and \( A \cap C = \phi \) hold.

**THEOREM 11.** (i) The moment minimal function \( W(Z) \) of the \((0, X_x; 0)\)-class (where \( X_x \in C_x \) is fixed) exists if and only if
\begin{equation}
W(Z) \det \frac{dW(Z)}{dZ} = X_x \det X_x M^0_{\mathcal{F}^*}(Z, 0) \quad \text{for } Z \in D.
\end{equation}

(ii) Suppose that a moment minimal function \( \eta(Z) \) of the extended class \( \mathcal{F} \) exists, then
\begin{equation}
\eta(Z) \det \frac{d\eta(Z)}{dZ} = \bar{X} \det \bar{X} M^0_{\mathcal{F}^*}(Z, 0),
\end{equation}
where
\begin{equation}
\bar{X} = (\det \Omega_D)^{1/2n} U \Omega_D^{-1/2} = UT_D^{1/2}(0, 0) / (\det T_D(0, 0))^{1/2n}.
\end{equation}
Here

\[(54) \quad \Omega_{D} = (0, I_{n})(H_{D}(0, 0))^{-1}(0, I_{n})' = T_{D}^{-1}(0, 0)/k_{00}\]

is a positive definite Hermitian matrix and $U$ is an arbitrary constant unitary matrix.

Let $D_{z}$ and $\Delta$ be the moment minimal domain of the $[0, I_{n}; 0]^{D}$-equivalent class and a moment minimal domain of the $\mathcal{F}$-equivalent class respectively, then the following inequality holds:

\[\int_{\varphi_{\eta}} \eta^{*} \eta dv_{\eta} \leq \int_{D_{z}} Z^{*} Z dv_{z}.\]

(iii) $\Delta$ is a moment minimal domain of the $\mathcal{F}$-equivalent class if and only if

\[(55) \quad M_{D}^{\mathcal{F}_{n}}(\eta, 0) = \eta \quad \text{for} \quad \eta \in \Delta\]

and

\[(56) \quad \Omega_{\Delta} = (\det \Omega_{\Delta})^{1/n} I_{n} \quad (\text{scalar matrix}),\]

that is,

\[(57) \quad T_{\Delta}(0, 0) = (\det T_{\Delta}(0, 0))^{1/n} I_{n} \quad (\text{scalar matrix}).\]

Proof. (i) From (23) and (45)

\[M_{D}^{\mathcal{F}_{n}}(Z, 0) = M_{j}^{0, X_{1}^{-1}} d_{X_{1}}(W, 0) \det \frac{dW}{dZ}\]

and

\[W(Z) \det \frac{dW(Z)}{dZ} = X_{1} \det X_{1} M_{D}^{\mathcal{F}_{n}}(Z, 0) = X_{1} \det X_{1} M_{D}^{0, X_{1}^{-1}} d_{X_{1}}(W, 0) \det \frac{dW}{dZ}\]

hold. Hence we have

\[W(Z) = M_{D}^{\mathcal{F}_{n}}(W, 0).\]

This shows that, from (36), $\Delta = W(D)$ is the moment minimal domain of the $[0, I_{n}; 0]^{d}$-equivalent class $([0, X_{1}; 0]^{D}$-equivalent class).

Conversely, suppose that $W(Z)$ is the moment minimal function of the $(0, X_{1}; 0)$-class. Since $W(Z) \det (dW/dZ)$ belongs to the $(0, X_{1} \det X_{1}; 0)$-class, we have

\[W(Z) \det \frac{dW}{dZ} = M_{D}^{0, X_{1} \det X_{1}}(Z, 0) = X_{1} \det X_{1} M_{D}^{\mathcal{F}_{n}}(Z, 0).\]
(ii) This has been essentially proved in our paper [10].
(iii) By (2)
\[ k_D(0, 0) = k_{D,0}^* = k_{D,10}^* = k_D(0, 0), \quad k_{D,10}^* = k_{D,11}^* = k_{D,11}^* \]
hold, where \( \Delta = \eta(D) \). Therefore we have
\[ \Omega = \tilde{X} \Omega_D \tilde{X}^*, \quad \tilde{X} = (\det \Omega_D)^{-1/2} \Omega_D^{-1/2}, \]
and
\[ (\det \Omega_D)^{-1/2} \Omega_D^{-1} = [\det (\tilde{X} \Omega_D \tilde{X}^*)]^{1/2} (\tilde{X} \Omega_D \tilde{X}^*)^{-1} = (\det \Omega_D)^{-1/2} (\det \Omega_D)^{-1} \Omega_D^{-1} = I_n, \]
because \( \Omega_D^{1/2} = \Omega_D \).

If \( \Delta = \eta(D) \) is a moment minimal domain of the \( \mathcal{F} \)-equivalent class, then \( \Delta \) is the moment minimal domain of the \([0, I_n; 0]D \)-equivalent class. Furthermore from (36)
\[ M_{\eta}(\eta, 0) = \eta \quad \text{for} \quad \eta \in \Delta, \]
and the converse is true.

**Corollary 4.** (i) If \( D_z \) and \( D_w \) are the moment minimal domains of the \([0, I_n; 0]D_z \)-and the \([0, I_n; 0]D_w \)-equivalent classes, respectively, and \( W = W(Z) \) (which maps \( D_z \) onto \( D_w \)) belongs to the \([0, \tilde{X}_1; 0]D_z \)-class, then the moment minimal function \( W(Z) \) is uniquely given by
\[ W = W(Z) = X, Z. \]
(ii) If \( \Delta_\eta \) is a moment minimal domain of the \( \mathcal{F} \)-equivalent class, then the moment minimal function \( \eta = \eta(Z) \) (which maps \( D_z \) onto \( \Delta_\eta \)) is given by
\[ \eta = \eta(Z) = \tilde{X}Z, \quad \tilde{X} = (\det \Omega_D)^{-1/2} \Omega_D^{1/2}, \]
where \( \tilde{X} \) is defined in Theorem 11.

**Proof.** Since \( D_z \) is the moment minimal domain of the \([0, I_n; 0]D_z \)-equivalent class,
\[ M_{D_z}(Z, 0) = Z \quad \text{for} \quad Z \in D_z \]
holds. From Theorem 11 (ii) it follows that
\[ W(Z) \det \frac{dW(Z)}{dZ} = (\det X_1) X_1 M_{D_z}(Z, 0) = (\det X_1) X_1 Z. \]
is a necessary and sufficient condition that \( W(Z) \) (if it exists) is the moment minimal function of the \([0, X_1; 0]^{\text{ss}}\)-equivalent class. On the other hand, the function (58) satisfies (60) for \( Z \in D_z \). Thus from Theorem 5, (58) is the unique and holomorphic moment minimal function of the \([0, I_n; 0]^{\text{ss}}\)-equivalent class.

(ii) As in (i), by (52) of Theorem 11, (59) is the unique moment minimal function of \( \mathcal{F} \) up to the constant unitary matrices.

**Corollary 5.** All moment minimal domains in the \( \mathcal{F} \)-equivalent class preserve their volumes (cf. Theorem 9 (i), (ii)).

*Proof.* By Corollary 4, if \( W = W(Z) \) is the mapping which maps a moment minimal domain \( D \) onto another moment minimal domain \( \Delta \) in the \( \mathcal{F} \)-equivalent class, then we have

\[
W = W(Z) = X, \quad |\det X| = 1.
\]

Since

\[
\text{vol}(\Delta) = \int_D dv_w = \int_D \left| \det \frac{dW(Z)}{dZ} \right|^2 dv_z = \int_D |\det X|^2 dv_z = \text{vol}(D),
\]

\( W = W(Z) \) is a volume preserving mapping.

**Theorem 12.** Let \( A, B \) and \( C \) denote the sets of minimal, representative and moment minimal domains in the \( \mathcal{F} \)-equivalent class, respectively. If any one of the relations \( A \cap B \neq \phi \), \( A \cap C \neq \phi \) and \( B \cap C \neq \phi \) holds, then \( A \supset B = C \) (cf. Corollary 3).

*Proof.* If \( A \cap B \neq \phi \), then all domains belonging to \( B \) are minimal domains by Theorem 9 (ii) and all domains belonging to \( B \) belong to \( C \) by Theorem 6. Further, by Corollary 5, \( C \subset A \) and hence by Theorem 6, \( C \subset B \). Thus we obtain \( A \supset B = C \). In the case \( A \cap C \neq \phi \) or \( B \cap C \neq \phi \), we have an analogous result.

**Example 2.** The Cartan domains (bounded irreducible symmetric domains of the four main types) are defined as follows: The first three types \( D_1, D_2 \) and \( D_3 \) are represented by

\[
\{ Z \mid I_n - ZZ^* > 0 \},
\]

where \( Z \) denotes an \((n \times m)\)-matrix on \( D_1 \), \( Z \) denotes an \((n \times n)\)-symmetric matrix with diagonal elements multiplied by \( \sqrt{2} \) on \( D_2 \) and \( Z \) denotes an \((n \times n)\)-skew-symmetric matrix on \( D_3 \). The fourth type \( D_4 \) is the set of \( n \)-dimensional row vectors \( Z \) such that

\[
|ZZ'| < 1, \quad 1 - 2ZZ^* + |ZZ'|^2 > 0.
\]
They are all minimal and also representative domains [7], [10]. Therefore by Theorem 6 they are moment minimal domains of the $[0, I_\ast; 0]^{p_i}$-equivalent classes ($i = 1, 2, 3, 4$), respectively. Further,

$$T_{D_4}(0, 0) = (k_{00} k_{11}^* - k_{01} k_{10}^*)/k_{00}^2 = k_{11}^*/k_{00}^* = A_i \quad (i = 1, 2, 3, 4)$$

hold, where

$$A_1 = (m + n)I_{mn}, \quad A_2 = 2(n + 1)I_{m(n+1)/2}, \quad A_3 = 2(n - 1)I_{n(n-1)/2}$$

and $A_4 = 2n I_\ast$ (property (57)). Therefore, they are moment minimal domains with respect to $\mathcal{F}(D_i)$ ($i = 1, 2, 3, 4$), respectively. Further in the $\mathcal{F}$-equivalent class of each one of Cartan domains, the set of all representative domains and the set of all moment minimal domains coincide and they are a subset of the set of minimal domains.

**Example 3.** Bounded complete circular domains are minimal and also representative domains with center at the origin [3]. Thus each domain $D$ of them is the moment minimal domain with respect to the $[0, I_\ast; 0]^{p}$-equivalent class, but it may not be a moment minimal domain of the $\mathcal{F}(D)$-equivalent class without property (57), which is equivalent to the “property A” mentioned in J. Mitchell’s paper [7] in the case of bounded complete circular domains.
