**ON THE NUMBER OF NONPIERCING POINTS IN CERTAIN  
CRUMPLED CUBES**

ROBERT JAY DAVERMAN

## ON THE NUMBER OF NONPIERCING POINTS IN CERTAIN CRUMPLED CUBES

ROBERT J. DAVERMAN

Let  $K$  denote the closure of the interior of a 2-sphere  $S$  topologically embedded in Euclidean 3-space  $E^3$ . If  $K - S$  is an open 3-cell, McMillan has proved that  $K$  has at most one nonpiercing point. In this paper we use a more general condition restricting the complications of  $K - S$  to describe the number of nonpiercing points. The condition is this: for some fixed integer  $n$   $K - S$  is the monotone union of cubes with  $n$  holes. Under this hypothesis we find that  $K$  has at most  $n$  nonpiercing points (Theorem 5). In addition, the complications of  $K - S$  are induced just by these nonpiercing points. Generally, at least two such points are required, for otherwise  $n = 0$  (Theorem 3).

A space  $K$  as described above is called a *crumpled cube*. The *boundary* of  $K$ , denoted  $\text{Bd } K$ , is defined by  $\text{Bd } K = S$ , and the *interior* of  $K$ , denoted  $\text{Int } K$ , is defined by  $\text{Int } K = K - \text{Bd } K$ . We also use the symbol  $\text{Bd}$  in another sense: if  $M$  is a manifold with boundary, then  $\text{Bd } M$  denotes the boundary of  $M$ . This should not produce any confusion.

Let  $K$  be a crumpled cube and  $p$  a point in  $\text{Bd } K$ . Then  $p$  is a *piercing point* of  $K$  if there exists an embedding  $f$  of  $K$  in the 3-sphere  $S^3$  such that  $f(\text{Bd } K)$  can be pierced with a tame arc at  $f(p)$ .

Let  $U$  be an open subset of  $S^3$ . The *limiting genus* of  $U$ , denoted  $\text{LG}(U)$ , is the least nonnegative integer  $n$  such that there exists a sequence  $H_1, H_2, \dots$  of compact 3-manifolds with boundary satisfying (1)  $U = \bigcup H_i$ , (2)  $H_i \subset \text{Int } H_{i+1}$ , and (3)  $\text{genus } \text{Bd } H_i = n$  ( $i = 1, 2, \dots$ ). If no such integer exists,  $\text{LG}(U)$  is said to be infinite. Throughout this paper the manifolds  $H_i$  described above can be obtained with connected boundary, in which case  $H_i$  is called a *cube with  $n$  holes*.

Applications of the finite limiting genus condition are investigated in [6] and [14]. For any crumpled cube  $K$  such that  $\text{LG}(\text{Int } K)$  is finite and  $\text{Bd } K$  is locally peripherally collared from  $\text{Int } K$ , it is shown that  $\text{Bd } K$  is locally tame (from  $\text{Int } K$ ) except at a finite set of points. Under the hypothesis of this paper,  $\text{Bd } K$  may be wild at every point; nevertheless, with a collapsing (in the sense of Whitehead [15]) argument comparable to [13, Th. 1], the problem of counting the nonpiercing points of  $K$  is reduced to one in which the results of [6] and [14] apply.

A subset  $X$  of the boundary of a crumpled cube  $K$  is said to be *semi-cellular in  $K$*  if for each open set  $U$  containing  $X$  there exists

an open set  $V$  such that  $X \subset V \subset U$  and loops in  $V - X$  are null homotopic in  $U - X$ . In the last section of this paper semi-cellular sets are discussed in order to characterize those sewings of two crumpled cubes which yield  $S^3$ , in case the limiting genus of one of the crumpled cubes is finite.

A simple closed curve  $J$  is *essential in an annulus*  $A$  if  $J$  lies in  $A$  and bounds no disk in  $A$ .

If  $X$  is a set in a topological space, then  $\text{Cl } X$  denotes the closure of  $X$ .

## 2. A cellularity criterion.

LEMMA 1. *Let  $H$  be a sphere with  $n$  handles. Then there exists an integer  $k(n)$  such that if  $J_1, \dots, J_{k(n)}$  are mutually exclusive simple closed curves in  $H$ , no one of which bounds a disk in  $H$ , then some pair  $\{J_r, J_s\}$  bounds an annulus in  $H$ .*

*Proof.* The number  $k(n) = 2$  is known to work if  $n = 1$ . Otherwise, the proof proceeds by induction, using  $k(n) = 3n - 2$  whenever  $n \geq 2$ .

THEOREM 2. *Let  $C$  be a crumpled cube such that  $\text{LG}(\text{Int } C) = n < \infty$ . Then there exists a finite set  $Q$  of points in  $\text{Bd } C$  such that for each open set  $U \supset \text{Bd } C$ , each point of  $\text{Bd } C - Q$  has a neighborhood  $V$  such that any loop in  $V - \text{Bd } C$  is null-homotopic in  $U - \text{Bd } C$ .*

*Proof.* Assume  $n > 0$ . Using Lemma 1 we associate with a sphere with  $n$  handles an integer  $k(n)$ . Let  $k = \max\{3, k(n)\}$ . Suppose  $p_1, p_2, \dots, p_{2k}$  are points in  $\text{Bd } C$  and  $U$  is an open set containing  $\text{Bd } C$ . It suffices to show that one of these points has a neighborhood  $V$  such that each loop in  $V - \text{Bd } C$  is nullhomotopic in  $U - \text{Bd } C$ .

*Step 1. Preliminary constructions.* There exists a collection of mutually exclusive disks  $D_1, \dots, D_{2k}$  on  $\text{Bd } C$  with  $p_i \in \text{Int } D_i$  ( $i = 1, \dots, 2k$ ). Furthermore,  $\text{Bd } C$  contains another collection of mutually exclusive disks  $E_1, \dots, E_k$  such that for  $i = 1, \dots, k$

$$D_{2i-1} \cup D_{2i} \subset \text{Int } E_i.$$

We consider  $C$  to be embedded in  $S^3$  so that the closure of  $S^3 - C$  is a 3-cell [8, 10]. We select a point  $b$  of  $\text{Int } C$  and construct arcs  $B_1, \dots, B_{2k}$  such that (1) distinct arcs  $B_i$  and  $B_j$  intersect only at the point  $b$ , (2) the endpoints of  $B_i$  are  $b$  and  $p_i$ , and (3)  $B_i$  is locally tame mod  $p_i$  ( $i = 1, \dots, 2k$ ).

By Theorem 1 of [3] there exist pairwise disjoint annuli

$$D_1^*, D_2^*, \dots, D_{2k}^*, E_1^*, E_2^*, \dots, E_k^*$$

in  $S^3$  such that

- (4)  $\text{Bd } D_i^* \supset \text{Bd } D_i$  and  $\text{Bd } E_j^* \supset \text{Bd } E_j$ ,
- (5)  $D_i^* \cap \text{Bd } C \subset D_i$ ,
- (5')  $E_j^* \cap \text{Bd } C \subset E_j - (D_{2j-1} \cup D_{2j})$ ,
- (6)  $(\cup (\text{Bd } D_i^* - \text{Bd } D_i)) \cup (\cup (\text{Bd } E_j^* - \text{Bd } E_j)) \subset \text{Int } C$ ,
- (7)  $D_i^*(E_j^*)$  is locally polyhedral mod  $\text{Bd } D_i$  ( $\text{Bd } E_j$ ), and
- (8)  $((\cup D_i^*) \cup (\cup E_j^*)) \cap (\cup B_i) = \emptyset$ .

If a surface approximating  $\text{Bd } C$  is to intersect the  $D_i^*$ 's and  $E_j^*$ 's properly, we must force it to lie very close to  $\text{Bd } C$ . To do this, first we thicken certain subsets of  $\text{Bd } C$ , thereby obtaining mutually exclusive open sets  $W_0, W_1, \dots, W_{3k}$  such that

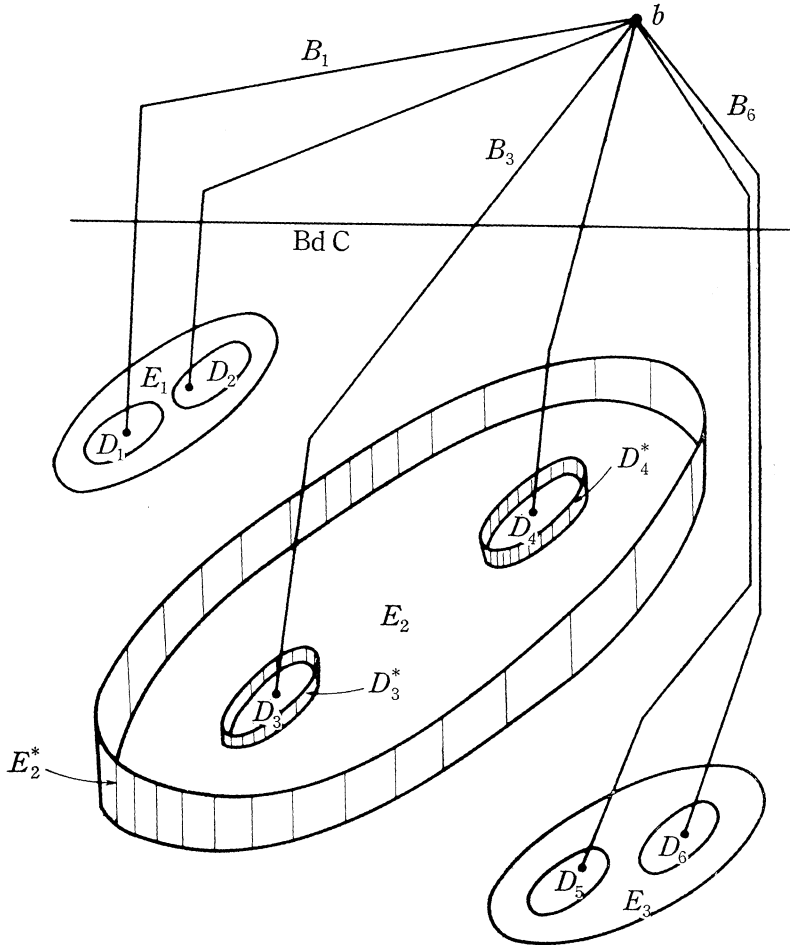

FIGURE 1

- (9)  $W_i \cap C \subset U - ((\cup \text{Bd } D_i^*) \cup (\cup \text{Bd } E_j^*)),$
- (10)  $W_0 \supset \text{Bd } C - ((\cup D_i) \cup (\cup E_j)),$
- (11)  $W_i \supset \text{Int } D_i \ (i = 1, \dots, 2k),$
- (12)  $W_{2k+i} \supset \text{Int } E_i - (D_{2i-1} \cup D_{2i}) \ (i = 1, \dots, k),$
- (13)  $(\cup W_j) \cap B_i = W_i \cap B_i \ (i = 1, \dots, 2k).$

In addition, we require that  $\text{Bd } D_i \cap \text{Cl } W_s \neq \emptyset$  only if  $s = 2k + i$  or  $s = i$  and  $\text{Bd } E_j \cap \text{Cl } W_s \neq \emptyset$  only if  $s = 0$  or  $s = 2k + j$ . Then we construct a neighborhood  $Y$  of  $\text{Bd } C - \cup W_i$  such that  $Y \cap C \subset U$  and any arc in  $\text{Int } C \cap (Y \cup (\cup W_i))$  from a point of  $W_i$  to a point of  $W_j$  intersects all the annuli in between. For example, if  $A$  is an arc from  $W_0$  to  $W_1$ , then  $A$  intersects both  $E_1^*$  and  $D_1^*$ .

By hypothesis  $\text{Int } C$  contains a cube with  $n$  holes  $M$  such that  $C - (Y \cup (\cup W_i)) \subset \text{Int } M$ . Without loss of generality, we assume that  $\text{Bd } M$  is polyhedral and in general position with respect to

$$(\cup \text{Int } E_j^*) \cup (\cup \text{Int } D_i^*).$$

*Step 2. A special disk in  $\text{Bd } M$ .* Let  $G$  denote the collection of those components of  $\text{Bd } M \cap ((\cup E_j^*) \cup (\cup D_i^*))$  which are essential simple closed curves in any annulus  $E_j^*$  or  $D_i^*$ . Each annulus  $E_j^*(D_i^*)$  contains a curve in the collection  $G$ , because  $\text{Bd } M$  separates the components of  $\text{Bd } E_j^*(\text{Bd } D_i^*)$ .

In the next paragraphs we show that at least one of the curves in  $G$  bounds a disk in  $\text{Bd } M$ . Suppose the contrary. From Lemma 1 we find that  $\text{Bd } M$  contains an annulus  $A$  such that  $\text{Bd } A = J_r \cup J_s$ , where  $J_r$  and  $J_s$  are essential curves on  $E_r^*$  and  $E_s^*$ , respectively, and  $r \neq s$ . This reduces to the case in which each component of  $\text{Int } A \cap (\cup E_j^*)$  bounds a disk in  $\cup E_j^*$ . Assume  $r \neq 1 \neq s$ .

*Case A. No component of  $A \cap (\cup E_j^*)$  separates the components of  $\text{Bd } A$ .* Let  $L$  be a simple closed curve in  $S^3 - (E_1^* \cup E_r^*)$  such that  $L \cap C = B_2 \cup B_{2r}$ . It follows from the constructions of Step 1 that each point of  $L \cap A$  is separated (in  $A$ ) from  $J_s$  by a component of  $\text{Int } A \cap (E_1^* \cup E_r^*)$ ; thus, by trading certain disks in  $\text{Int } A$  for disks in  $E_1^* \cup E_r^*$ , we see that  $J_r$  and  $J_s$  are homotopic in  $S^3 - L$ . But this is impossible, since  $J_r$  links  $L$  and  $J_s$  does not.

*Case B. Some component of  $A \cap (\cup E_j^*)$  separates the components of  $\text{Bd } A$ .* By considering all components of  $A \cap ((\cup E_j^*) \cup (\cup D_i^*))$ , we find that  $A$  contains an annulus  $A'$  such that no curve in

$$\text{Int } A' \cap ((\cup E_j^*) \cup (D_i^*))$$

is essential in  $A'$  and  $J_r \subset \text{Bd } A'$ . Let  $J'$  denote the other component of  $\text{Bd } A'$ , and without loss of generality assume that  $J' \cap D_{2r}^* = \emptyset$ .

Let  $L'$  be a simple closed curve in  $S^3 - ((\cup E_j^*) \cup (\cup D_i^*))$  such that  $L' \cap C = B_2 \cup B_{2r}$ . Each point of  $L' \cap A'$  is separated in  $A'$  from either  $J_r$  or  $J'$  by  $\text{Int } A'((\cup E_j^*) \cup (\cup D_i^*))$ , and each curve of this intersection bounds disks in both  $A'$  and  $(\cup E_j^*) \cup (\cup D_i^*)$ . Hence, by the usual disk trading, we see that  $J_r$  is homotopic to  $J'$  in  $S^3 - L'$ . Again this leads to a contradiction, for  $J_r$  links  $L'$ ; on the other hand,  $J'$  either is contained in  $D_{2r-1}^*$  or is an inessential curve in some  $E_j^*$ , which implies that  $J'$  does not link  $L'$ .

Neither of the two cases can occur. Consequently, some simple closed curve  $J$  in the collection  $G$  bounds a disk in  $\text{Bd } M$ .

*Step 3.* A neighborhood  $V$  of one of the points  $p_i$ . Corresponding to one of the points, say  $p_1$ , there exists a disk  $D \subset \text{Bd } M$  such that  $\text{Bd } D$  is an essential curve in  $D_1^*$ , but each component of  $\text{Int } D \cap (\cup D_i^*)$  bounds a disk in  $\cup D_i^*$ . Repeating this process, it follows that for one of the  $p_i$ 's, say  $p_1$  again, and for each open set  $U'$  containing  $\text{Bd } C$ , there exists a polyhedral disk  $E$  in  $U' \cap \text{Int } C$  such that  $\text{Bd } E$  is an essential simple closed curve on  $D_1^*$  but each component of  $(\text{Int } E \cap (\cup D_i^*))$  bounds a disk in  $\cup D_i^*$ .

To find the desired open set in  $C$ , let  $V'$  be a spherical neighborhood of  $p_1$  such that  $V' \cap C \subset W_1$ , and define  $V = V' \cap C$ . For any loop  $L$  in  $V - \text{Bd } C$ , another linking argument shows that  $L$  is separated from  $\text{Bd } C$  (in  $V$ ) by some disk  $E \subset U$  as described above. Since  $L$  is contractible in  $V'$ , it follows from [5, Lemma 1] that  $L$  is contractible in  $U - \text{Bd } C$ . This completes the proof.

**THEOREM 3.** *Suppose  $C$  is a crumpled cube such that  $\text{LG}(\text{Int } C) < \infty$  and  $C$  contains at most one nonpiercing point. Then  $\text{Int } C$  is an open 3-cell.*

*Proof.* Assume  $C$  is embedded in  $S^3$  so that the closure of  $S^3 - C$  is a 3-cell  $K$  [8, 10]. Equivalently, we show that  $K$  is a cellular subset of  $S^3$ .

Let  $Q$  denote the finite set of points of  $\text{Bd } C$  given by Theorem 2,  $p$  the nonpiercing point of  $C$  (the argument when  $C$  has no nonpiercing point is essentially the same), and  $U$  an open set containing  $K$ . There exists an open set  $V$  containing  $K$  such that loops in  $V - K$  are null-homotopic in  $U - (\text{Int } K \cup p)$ . Let  $f$  be a map of a disk  $\Delta$  into  $U - (\text{Int } K \cup p)$  such that  $f(\text{Bd } \Delta) \subset V - K$ . It follows from [12, Th. 2] and techniques of [2, Th. 4.2] that  $f$  can be adjusted slightly at points of  $\text{Int } \Delta$  so that  $f(\Delta) \cap \text{Bd } C$  is 0-dimensional and  $f(\Delta) \cap Q = \emptyset$ . Finally, there exists a finite number of mutually exclusive simple closed curves  $S_1, \dots, S_k$  in  $\Delta$  whose union separates  $\text{Bd } \Delta$  from  $f^{-1}(f(\Delta) \cap \text{Bd } C)$  and such that  $f|_{S_i}$  is null homotopic in

$U - K$  ( $i = 1, \dots, k$ ). This implies that  $f|_{\text{Bd } \Delta}$  extends to a map of  $\Delta$  into  $U - K$ . According to McMillan's Cellularity Criterion [11, Th. 1'],  $K$  is a cellular subset of  $S^3$ .

**3. Topological collapsing.** The following result generalizes Theorem 1 of [13]. The argument below necessarily differs from McMillan's, since we have no mapping criterion to determine the finite limiting genus condition.

**THEOREM 4.** *Suppose  $K$  is a finite connected simplicial complex,  $L$  a subcomplex of  $K$  such that  $K$  collapses to  $L$ , and  $h$  a homeomorphism of  $K$  into  $S^3$  such that  $\text{LG}(S^3 - h(K)) = n$ . Then*

$$\text{LG}(S^3 - h(L)) \leq n .$$

*Proof.* It is sufficient to show that the result holds if  $L$  is obtained from  $K$  by a single elementary collapse. Suppose that  $\sigma$  is a principal simplex of  $K$ ,  $\tau$  is a proper face of  $\sigma$  such that  $\tau$  is a proper face of no other simplex in  $K$ , and

$$L = K - \text{Int } \sigma - \text{Int } \tau .$$

We consider the case when  $\sigma$  is a 3-simplex, because the applications of Theorem 4 in this paper can be viewed as involving collapses of this type only; for the remaining cases a similar argument applies.

Let  $U$  be an open subset of  $S^3$  containing  $h(L)$ . There exists a neighborhood  $U^*$  of  $h(L)$  in  $U$  such that some component  $Z$  of  $h(\sigma) - U^*$  contains  $h(\sigma) - U$ . Using [4, Th. 4] we find a tame disk  $D$  in  $U^* - h(L)$  such that  $\text{Bd } D \cap h(K) = \emptyset$  and exactly one of the components of  $D \cap h(\sigma)$  separates  $Z$  from  $h(L \cap \sigma)$  in  $h(\sigma)$ .

There exists a neighborhood  $W$  of  $h(K)$  such that  $W \cap \text{Bd } D = \emptyset$  and  $W$  can be deformed to  $h(K)$  in  $S^3 - \text{Bd } D$  by a homotopy keeping  $h(K)$  pointwise fixed. For each point  $x$  in  $U \cap h(K)$  define an open set  $N_x$  as

$$N_x = \{y \in S^3 \mid \rho(x, y) < \rho(x, \text{Bd } U \cup \text{Bd } W)\}$$

and for each point  $x$  in  $h(\sigma) - U$  define  $N_x$  as

$$N_x = \{y \in S^3 \mid \rho(x, y) < \rho(x, D \cup \text{Bd } W)\} .$$

Then let  $V = \bigcup_{x \in h(K)} N_x$ .

*Claim.*  $D \cap V$  separates  $Z$  from  $h(L)$  in  $V$ , and  $U$  contains the component  $Y$  of  $V - D$  that contains  $h(L)$ .

Suppose there exists an arc  $\alpha$  in  $V - D$  from a point of  $Z$  to a

point of  $h(L)$ . Then  $\alpha$  is homotopic in  $S^3 - \text{Bd } D$  (with endpoints fixed) to a path  $\alpha'$  in  $h(K)$ , and  $\alpha'$  is homotopic in  $h(K)$  (with endpoints fixed) to a path  $\alpha^*$  such that  $\alpha^* \cap D$  consists of a finite set of points at which  $\alpha^*$  pierces  $D$ . But then the number of such points must be even, contradicting the separation properties of  $D$  in  $h(K)$ .

To establish the other part of the claim, suppose there exists a point  $y$  in  $Y - U$ . Then  $y \in N_x$  for some  $x$  in  $h(\sigma) - U$ . Let  $A$  be the straight line segment from  $y$  to  $x$  in  $N_x$ , and let  $B$  denote an arc from  $y$  to  $h(L)$  in  $Y$ . Since  $A \cup B$  does not intersect  $D$ , deforming  $A \cup B$  to a path in  $h(K)$  leads to a contradiction as before. This completes the proof of the claim.

By hypothesis  $S^3 - h(K)$  contains a polyhedral cube with  $n$  holes  $H$  such that  $\text{Int } H \supset S^3 - V$ . We adjust  $H$  slightly so that  $\text{Bd } H \cap D$  consists of a finite number of simple closed curves. Note that  $D \cup (\text{Bd } H \cap U)$  separates  $h(L)$  from  $h(\sigma) - U$  (in  $S^3$ ). Thus, the unicoherence of  $S^3 - D$  implies that some component  $F$  of  $\text{Bd } H - D$ , where  $F \subset U$ , separates  $h(L)$  from  $h(\sigma) - U$  in  $S^3 - D$ .

We observe that  $\text{Cl } F$  is a disk with  $k$  ( $k \leq n$ ) handles and (possibly) some holes. By attaching disks to  $\text{Bd } F$  near  $D$ , we see that  $F$  is contained in a sphere with  $k$  handles  $S_k$  in  $\text{Cl}(S^3 - h(L))$  and that  $S_k$  bounds a cube with  $k$  holes  $M$  satisfying

$$S^3 - U \subset M \subset S^3 - h(L) .$$

This implies that  $\text{LG}(S^3 - h(L)) \leq n$ .

#### 4. The number of nonpiercing points.

**THEOREM 5.** *If  $C$  is a crumpled cube such that  $\text{LG}(\text{Int } C) = n$  ( $1 \leq n < \infty$ ), then  $C$  has at most  $n$  nonpiercing points.*

*Proof.* Suppose to the contrary that  $C$  contains at least  $n + 1$  nonpiercing points  $p_1, \dots, p_{n+1}$ . As before we assume  $C$  is embedded in  $S^3$  so that the closure of  $S^3$  of  $S^3 - C$  is a 3-cell  $H$  [8, 10]. Let  $h$  denote a homeomorphism of a 3-simplex  $\mathcal{A}^3$  onto  $H$ .

Some triangulation  $K$  of  $\mathcal{A}^3$  collapses to a subcomplex  $L$  such that  $h(L)$  is a 3-cell locally tame except at  $p_1, \dots, p_{n+1}$ ; thus, each point  $p_i$  is a nonpiercing point of  $\text{Cl}(S^3 - h(L))$ . Theorem 4 gives that  $\text{LG}(S^3 - h(L)) \leq n$ . This leads to a contradiction, however, for either [6, Th. 2] or [14, Th. 1] implies that  $\text{Cl}(S^3 - h(L))$  has at most  $n$  nonpiercing points.

**COROLLARY.** *If  $C$  is a crumpled cube such that  $\text{LG}(\text{Int } C) \leq 1$ , then  $\text{Int } C$  is an open 3-cell.*

The techniques used to prove Theorem 5 can be reapplied to obtain the following result.

**THEOREM 6.** *If  $H$  is a cube with  $k$  handles in  $S^3$  and*

$$\text{LG}(S^3 - H) = n \ (1 \leq n < \infty) ,$$

*then  $\text{Bd } H$  is pierced by a tame arc at all but (at most)  $n - k$  of its points.*

To describe the number of nonpiercing points precisely requires some additional definitions. Let  $A$  be an arc in  $S^3$  locally tame modulo an endpoint  $p$ . The *local enveloping genus* of  $A$  at  $p$ , denoted  $\text{LEG}(A, p)$ , is the smallest nonnegative integer  $r$  (if there is no such integer  $r$ ,  $\text{LEG}(A, p) = \infty$ ) such that there exist arbitrarily small neighborhoods of  $p$ , each of which is bounded by a surface of genus  $r$  (a sphere with  $r$  handles) that intersects  $A$  at exactly one point. Chapter 4 of [14] gives illustrations of arcs  $A_n$ , each locally tame mod an endpoint  $p_n$ , such that  $\text{LEG}(A_n, p_n) = n$  ( $n = 1, 2, \dots, \infty$ ).

Let  $B = \{(x, y, z) \in E^3 \mid x^2 + y^2 + z^2 \leq 1\}$ . Let  $f$  be a homeomorphism of  $B$  onto a 3-cell  $C$  in  $S^3$ , and  $p$  a point of  $\text{Bd } C$ . The *local enveloping genus* of  $C$  at  $p$ , denoted  $\text{LEG}(C, p)$ , is defined by

$$\text{LEG}(C, p) = \text{LEG}(f(\alpha), p) ,$$

where  $\alpha$  is the line segment in  $B$  from the origin to  $f^{-1}(p)$ .

**THEOREM 7.** *If  $C$  is a 3-cell in  $S^3$  such that  $\text{LG}(S^3 - C) = n$  ( $2 \leq n < \infty$ ) and  $p_1, \dots, p_k$  are the nonpiercing points of  $S^3 - \text{Int } C$ , then*

$$n = \sum_{i=1}^k \text{LEG}(C, p_i) .$$

*Proof.* As in the proof of Theorem 5, let  $h$  be a homeomorphism of a 3-simplex  $\Delta^3$  onto  $C$ . Some triangulation of  $\Delta^3$  collapses to a subcomplex  $L$  such that  $h(L)$  is a 3-cell locally tame modulo  $\cup p_i$ . It follows from the definition of local enveloping genus that the subcomplex  $L$  can be chosen to satisfy

$$\text{LEG}(C, p_i) = \text{LEG}(h(L), p_i) \quad (i = 1, \dots, k) .$$

Since  $\text{LG}(S^3 - h(L)) \leq n$ , Theorem 6 of [14] implies

$$n \geq \sum \text{LEG}(h(L), p_i) = \sum \text{LEG}(C, p_i) .$$

Let  $U$  be an open set containing  $C$ . To establish the inequality in the other direction, we shall find pairwise disjoint disks with handles

$G_1, \dots, G_k$  in  $U - \cup p_i$  subject to the following conditions: the number of handles on  $G_i$  is bounded by  $\text{LEG}(C, p_i)$ ,  $\text{Bd } G_i$  bounds an annulus  $A_i$  in  $G_i$  such that  $G'_i = \text{Cl}(G_i - A_i)$  is contained in  $U - C$ ,  $\text{Int } A_i \cap \text{Bd } C$  is contained both in a null sequence of pairwise disjoint disks in  $\text{Bd } C - \cup p_i$  and in a null sequence of such disks in  $\text{Int } A_i$ , and  $\cup \text{Bd } G_i$  bounds a disk with  $(k - 1)$  holes in  $\text{Bd } C - \cup p_i$ . Furthermore,  $G_i$  can be obtained arbitrarily close to  $p_i$ . Thus, in the next two paragraphs we describe how to find one such surface  $G_1$  near  $p_1$ .

In  $\text{Bd } C$  there exists a Sierpinski curve  $X$  locally tame mod  $p_1$  and containing  $p_1$  in its inaccessible part. By removing a null sequence of nice 3-cells from  $C$  we obtain a 3-cell  $C^*$  such that  $C^* \cap \text{Bd } C = X$  and  $C^*$  is locally tame mod  $p_1$ . It follows from the definition of local enveloping genus that arbitrarily close to  $p_1$  is a surface  $H$  such that  $H \cap C^*$  is a disk  $D$ , with  $D \cap \text{Bd } C^* = \text{Bd } D$ , and  $p_1$  lies interior to the small disk on  $\text{Bd } C^*$  bounded by  $\text{Bd } D$ . Adjust  $H$  near  $\text{Bd } C^*$  so that  $\text{Bd } D$  lies in the inaccessible part of  $X$ . Without moving any point of  $D$  adjust  $H$  further so that the nondegenerate components of  $(H - D) \cap \text{Bd } C$  comprise a null sequence of simple closed curves and that  $(H - D) \cap C^* = \emptyset$  [4, Th. 4]. Hence,

$$(H - D) \cap X = \emptyset .$$

Now consider the component  $K$  of  $H - C$  whose closure contains  $\text{Bd } D$ . Associate with each simple closed curve  $S_j$  of  $(\text{Bd } K - \text{Bd } D)$  a disk  $F_j$  in  $C - C^*$  such that

- (1)  $F_j \cap \text{Bd } C = \text{Bd } F_j = S_j$ ,
- (2)  $F_j \cap F_k = \emptyset$  if  $S_j \cap S_k = \emptyset$ ,
- (3)  $\lim_{j \rightarrow \infty} \text{diam } F_j = 0$ .

Define  $G_1 = (\cup F_j) \cup \text{Cl } K$ . Then  $G_1$  is a disk with handles, and the number of handles is bounded by  $\text{LEG}(C, p_1)$ . Note that  $\text{Bd } G_1 = \text{Bd } D$ . Since components of  $(G_1 - \text{Bd } G_1) \cup C$  are either arcs or points, we can readily obtain an annulus  $A_1$  in  $G_1$  such that  $\text{Bd } A_1$  contains  $\text{Bd } G_1$  and  $\text{Int } A_1$  contains  $(G_1 - \text{Bd } G_1) \cap C$ , and now the remaining requirements on  $G_1$  must be satisfied.

Applying Theorem 2 and techniques from the proof of Theorem 3, we find a map  $f$  of a disk with  $(k - 1)$  holes  $E$  into  $U - C$  such that

$$f(E) \cap G'_i = f(\text{Bd } E) \cap G'_i = \text{Bd } G'_i \quad (i = 1, \dots, k)$$

and  $f$  has no singularities near  $\text{Bd } E$ . According to [9, Lemma 1] there exists a homeomorphism  $f'$  of  $E$  into  $U - C$  such that

$$f'(E) \cap G'_i = f'(\text{Bd } E) \cap G'_i = \text{Bd } G'_i \quad (i = 1, \dots, k) .$$

Thus, if  $S$  denotes  $f'(E) \cup (\cup G'_i)$ ,  $S$  is a sphere with handles, and

the number of handles is bounded by  $\Sigma \text{LEG}(C, p_i)$ . Moreover,  $S$  can be obtained so as to separate  $S^3 - U$  from  $C$ . Finally, since  $U$  is an arbitrary open set, we have that

$$n \leq \Sigma \text{LEG}(C, p_i) .$$

### 5. Semi-cellular subsets.

**THEOREM 8.** *Suppose  $C$  is a crumpled cube such that*

$$2 \leq \text{LG}(\text{Int } C) < \infty ,$$

*and  $X$  is a nonseparating subcontinuum of  $\text{Bd } C$  containing only piercing points of  $C$ . Then  $X$  is semi-cellular in  $C$ .*

*Proof.* Let  $p_1, \dots, p_k$  denote the nonpiercing points of  $C$ , and  $D$  a disk in  $\text{Bd } C - \cup p_i$  whose interior contains  $X$ . If  $C$  is embedded in  $S^3$  so that  $\text{Cl}(S^3 - C)$  is a 3-cell  $K$ , then  $K$  collapses to a 3-cell  $K'$  which is locally tame mod  $(D \cup p_i)$ , with  $p_i$  a nonpiercing point of  $S^3 - \text{Int } K' = C'$ . According to Theorem 4,  $\text{LG}(\text{Int } C') < \infty$ . Since each point of  $D$  is a piercing point of  $C'$ , it follows from Theorem 3 that  $\text{Int } C'$  is an open 3-cell. Then  $X$  is semi-cellular in  $C'$  [7, Lemma 2.7]; clearly  $X$  must also be semi-cellular in  $C$ .

Theorem 8 can be applied to characterize those sewings of two crumpled cubes which yield  $S^3$ , when one of the crumpled cubes has finite limiting genus. With minor changes, such as in the references to the number of nonpiercing points, we can use the proof of [7, Th. 5.7] to prove Theorem 9.

**THEOREM 9.** *Suppose  $C_1$  and  $C_2$  are crumpled cubes,  $h$  is a homeomorphism of  $\text{Bd } C_1$  to  $\text{Bd } C_2$ , and  $\text{LG}(\text{Int } C_2) < \infty$ . Then  $C_1 \mathbf{U}_h C_2 = S^3$  if and only if each nonpiercing point of  $C_1$  is identified by  $h$  with a piercing point of  $C_2$ .*
