**MOORE SPACES AND  $w$   $\Delta$ -SPACES**

RICHARD EARL HODEL

## MOORE SPACES AND $w\mathcal{A}$ -SPACES

R. E. HODEL

*This paper is dedicated to Professor J. H. Roberts  
on the occasion of his sixty-fifth birthday.*

**This paper is a study of conditions under which a  $w\mathcal{A}$ -space is a Moore space. In §2 we introduce the notion of a  $G_\delta^*$ -diagonal and show that every  $w\mathcal{A}$ -space with a  $G_\delta^*$ -diagonal is developable. In §3 we prove that every regular  $\theta$ -refinable  $w\mathcal{A}$ -space with a point-countable separating open cover is a Moore space. In §4 we introduce the class of  $\alpha$ -spaces and show that a regular  $w\mathcal{A}$ -space is a Moore space if and only if it is an  $\alpha$ -space. Finally, in §5 we study a new class of spaces which generalizes both semi-stratifiable and  $w\mathcal{A}$ -spaces.**

1. Preliminaries. We begin with some definitions and known results which will be used throughout this paper. Unless otherwise stated no separation axioms are assumed; however regular spaces are always  $T_1$  and paracompact spaces are always Hausdorff. The set of natural numbers will be denoted by  $N$ .

Let  $X$  be a set,  $\mathcal{S}$  a cover of  $X$ ,  $x$  an element of  $X$ . The *star of  $x$  with respect to  $\mathcal{S}$* , denoted  $\text{st}(x, \mathcal{S})$ , is the union of all elements of  $\mathcal{S}$  containing  $x$ . The *order of  $x$  with respect to  $\mathcal{S}$* , denoted  $\text{ord}(x, \mathcal{S})$ , is the number of elements of  $\mathcal{S}$  containing  $x$ .

A space  $X$  is *developable* if there is a sequence  $\mathcal{S}_1, \mathcal{S}_2, \dots$  of open covers of  $X$  such that, for each  $x$  in  $X$ ,  $\{\text{st}(x, \mathcal{S}_n) : n = 1, 2, \dots\}$  is a fundamental system of neighborhoods of  $x$ . Such a sequence of open covers is called a *development* for  $X$ . A regular developable space is called a *Moore space*. Bing [1] proved that every paracompact Moore space is metrizable.

According to Borges [3] a space  $X$  is a  $w\mathcal{A}$ -space if there is a sequence  $\mathcal{S}_1, \mathcal{S}_2, \dots$  of open covers of  $X$  such that, for each  $x$  in  $X$ , if  $x_n \in \text{st}(x, \mathcal{S}_n)$  for  $n = 1, 2, \dots$  then the sequence  $\langle x_n \rangle$  has a cluster point. Such a sequence of open covers is called a  $w\mathcal{A}$ -sequence for  $X$ . Clearly every countably compact space is a  $w\mathcal{A}$ -space, and in [3] Borges proved that every developable space and every  $M$ -space is a  $w\mathcal{A}$ -space. For the relationship between  $w\mathcal{A}$ -spaces, strict  $p$ -spaces, and  $p$ -spaces, see [6].

A space  $X$  is *subparacompact* if every open cover of  $X$  has a  $\sigma$ -discrete closed refinement. Every paracompact space is subparacompact [16], and in [8] Creede proved that every semi-stratifiable space is subparacompact. For further properties of subparacompact spaces see [5], [11], and [15].

A space  $X$  is  $\theta$ -refinable if for each open cover  $\mathcal{V}$  of  $X$  there is a sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  of open refinements of  $\mathcal{V}$  such that, for each  $x$  in  $X$ , there is a  $n$  in  $N$  such that  $\text{ord}(x, \mathcal{G}_n)$  is finite. Such a sequence of open covers is called a  $\theta$ -refinement of  $\mathcal{V}$ . In [24] Wicke and Worrell state that every subparacompact space is  $\theta$ -refinable and that a countably compact  $T_1$  space is compact if and only if it is  $\theta$ -refinable.

2. Spaces with a  $G_\delta^*$ -diagonal. Recall that a space  $X$  has a  $G_\delta$ -diagonal if its diagonal  $\Delta = \{(x, x) : x \text{ in } X\}$  is a  $G_\delta$ -subset of  $X \times X$ . The notion of a  $G_\delta$ -diagonal plays an important role in metrization theorems; see, for example, [2], [3], [7], [14], and [22].

Every semi-stratifiable Hausdorff space has a  $G_\delta$ -diagonal [8]. On the other hand the space  $[0, 1] \times \{0, 1\}$  with the lexicographic order is a compact perfectly normal space which fails to have a  $G_\delta$ -diagonal [14].

In [7] Ceder obtained this characterization of spaces with a  $G_\delta$ -diagonal.

PROPOSITION 2.1. (Ceder) *A space  $X$  has a  $G_\delta$ -diagonal if and only if there is a sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  of open covers of  $X$  such that, for any two distinct points  $x$  and  $y$  of  $X$ , there is a  $n$  in  $N$  such that  $y \notin \text{st}(x, \mathcal{G}_n)$ .*

In light of this characterization of a  $G_\delta$ -diagonal and Borges' study of spaces with a  $\bar{G}_\delta$ -diagonal (see [3]), we introduce the following definition.

DEFINITION 2.2. A space  $X$  has a  $G_\delta^*$ -diagonal if there is a sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  of open covers of  $X$  such that, for any two distinct points  $x$  and  $y$  of  $X$ , there is a  $n$  in  $N$  such that  $y \notin \text{st}(x, \mathcal{G}_n)^-$ . Such a sequence of open covers is called a  $G_\delta^*$ -sequence for  $X$ .

In [13] Kullman proved that every regular  $\theta$ -refinable space with a  $G_\delta$ -diagonal has a  $\bar{G}_\delta$ -diagonal. Since every space with a  $\bar{G}_\delta$ -diagonal has a  $G_\delta^*$ -diagonal, we have the following proposition.

PROPOSITION 2.3. *Every regular  $\theta$ -refinable space with a  $G_\delta$ -diagonal has a  $G_\delta^*$ -diagonal. In particular every regular semi-stratifiable space has a  $G_\delta^*$ -diagonal.*

The next result relates the  $G_\delta^*$ -diagonal property to the diagonal  $\Delta$ .

PROPOSITION 2.4. *Let  $X$  be a space, let  $\{V_n : n = 1, 2, \dots\}$  be a*

sequence of open subsets of  $X \times X$  containing  $\Delta$ , and suppose that  $\bigcap_{n=1}^{\infty} \bar{V}_n = \Delta$ . Then  $X$  has a  $G_\delta^*$ -diagonal. In particular, if  $X$  is Hausdorff and  $X \times X$  is perfectly normal then  $X$  has a  $G_\delta^*$ -diagonal.

*Proof.* For  $n = 1, 2, \dots$  let  $\mathcal{G}_n = \{G \subseteq X: G \text{ open, } G \times G \subseteq V_n\}$ . Since  $V_n$  is open and contains  $\Delta$ ,  $\mathcal{G}_n$  covers  $X$ . To show that  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is a  $G_\delta^*$ -sequence for  $X$ , let  $x$  and  $y$  be distinct points of  $X$ . Choose  $n$  in  $N$  such that  $(x, y) \notin \bar{V}_n$ , and let  $U$  and  $W$  be open neighborhoods of  $x$  and  $y$  respectively such that  $(U \times W) \cap V_n = \emptyset$ . It follows that  $W \cap \text{st}(x, \mathcal{G}_n) = \emptyset$  and so  $y \notin \text{st}(x, \mathcal{G}_n)^-$ .

We now prove the main result in this section.

**THEOREM 2.5.** *Every  $w\Delta$ -space with a  $G_\delta^*$ -diagonal is developable.*

*Proof.* Let  $X$  be a space, let  $\mathcal{H}_1, \mathcal{H}_2, \dots$  be a  $w\Delta$ -sequence for  $X$ , and let  $\mathcal{K}_1, \mathcal{K}_2, \dots$  be a  $G_\delta^*$ -sequence for  $X$ . For each positive integer  $n$  let

$$\mathcal{G}_n = \left\{ G: G = \left( \bigcap_{i=1}^n H_i \right) \cap \left( \bigcap_{i=1}^n K_i \right), H_i \in \mathcal{H}_i, K_i \in \mathcal{K}_i, i = 1, \dots, n \right\}.$$

It is easy to check that  $\mathcal{G}_{n+1}$  is an open refinement of  $\mathcal{G}_n$  for all  $n$  in  $N$  and that  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is a  $w\Delta$ -sequence and a  $G_\delta^*$ -sequence for  $X$ .

Suppose that  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is not a development for  $X$ . Then there is a point  $x$ , a neighborhood  $W$  of  $x$ , and a sequence  $\langle x_n \rangle$  such that for all  $n$ ,  $x_n \in \text{st}(x, \mathcal{G}_n)$  and  $x_n \notin W$ . Since  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is a  $w\Delta$ -sequence for  $X$ , the sequence  $\langle x_n \rangle$  has a cluster point  $p$ . Clearly  $p \notin W$  so  $p \neq x$ . Since  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is a  $G_\delta^*$ -sequence for  $X$ , there is a positive integer  $k$  and a neighborhood  $V$  of  $p$  such that  $V \cap \text{st}(x, \mathcal{G}_k) = \emptyset$ . Now for  $n \geq k$ ,  $x_n \in \text{st}(x, \mathcal{G}_n) \subseteq \text{st}(x, \mathcal{G}_k)$  and so  $x_n \notin V$ . This contradicts the fact that  $p$  is a cluster point of  $\langle x_n \rangle$ . Thus  $\mathcal{G}_1, \mathcal{G}_2, \dots$  is a development for  $X$ .

**COROLLARY 2.6.** *The following are equivalent for a regular  $w\Delta$ -space  $X$ :*

- (a)  $X$  is a Moore space.
- (b)  $X$  is semi-stratifiable.
- (c)  $X$  is  $\theta$ -refinable and has a  $G_\delta$ -diagonal.
- (d)  $X$  has a  $G_\delta^*$ -diagonal.

*Proof.* The implication (a)  $\Rightarrow$  (b) is due to Creede [8]; (b)  $\Rightarrow$  (c) follows from results by Creede [8] and Wicke and Worrell [24]; (c)  $\Rightarrow$  (d) follows from Proposition 2.3; (d)  $\Rightarrow$  (a) follows from Theorem 2.5.

REMARK 2.7. The equivalence of (a) and (b) was first proved by Creede in [8], and the equivalence of (a) and (c) is due to Siwiec [23]. It is not known if every regular  $w\Delta$ -space with a  $G_\delta$ -diagonal is a Moore space. For a study of  $p$ -spaces with a  $G_\delta$ -diagonal, see [13].

COROLLARY 2.8. *The following are equivalent for a regular countably compact space  $X$ :*

- (a)  $X$  is metrizable.
- (b)  $X \times X \times X$  is completely normal.
- (c)  $X \times X$  is perfectly normal.
- (d)  $X$  has a  $G_\delta^*$ -diagonal.

*Proof.* Clearly (a)  $\Rightarrow$  (b); (b)  $\Rightarrow$  (c) follows from a theorem due to Katětov [12]; (c)  $\Rightarrow$  (d) follows from Proposition 2.4. To prove (d)  $\Rightarrow$  (a) observe that  $X$  is a Moore space (by Corollary 2.6) and recall that every countably compact Moore space is metrizable.

3. Separating covers. In 1938 Filippov [9] proved that every paracompact  $M$ -space with a point-countable base is metrizable. Filippov's theorem was generalized by Burke and Stoltenberg in [4], and recently Burke [6] obtained another generalization as follows.

BURKE'S THEOREM. *Every regular subparacompact  $w\Delta$ -space with a point-countable base is a Moore space.*

In another direction Nagata [20] proved a metrization theorem which not only generalizes Filippov's theorem but a result by Okuyama as well [22]. In order to state Nagata's theorem succinctly we use the following terminology due to Michael [17]. A cover  $\mathcal{V}$  of a set  $X$  is said to be *separating* if given distinct points  $x$  and  $y$  of  $X$ , there is a  $V$  in  $\mathcal{V}$  such that  $x \in V$ ,  $y \notin V$ .

NAGATA'S THEOREM. *Every paracompact  $M$ -space with a point-countable separating open cover is metrizable.*

In this section we use the techniques developed by Burke, Filippov, Nagata, and Stoltenberg, together with the results in §2, to obtain a generalization of the abovementioned theorems by Burke and Nagata.

In light of the usefulness of the concept of a  $\theta$ -base in the study of developable spaces (see [24]), we begin with the following definition.

**DEFINITION 3.1.** A  $\theta$ -separating cover of a space  $X$  is a sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  of open collections such that, for any two distinct points  $x$  and  $y$  in  $X$ , there is a  $n$  in  $N$  such that

- (a)  $\text{ord}(x, \mathcal{G}_n)$  is finite;
- (b) there is a  $G$  in  $\mathcal{G}_n$  such that  $x \in G$  and  $y \notin G$ .

The relationship between a  $\theta$ -separating cover and a  $G_\delta$ -diagonal is given by the following two propositions.

**PROPOSITION 3.2.** *Let  $X$  be a space with a  $\theta$ -separating cover. If every closed subset of  $X$  is a  $G_\delta$  then  $X$  has a  $G_\delta$ -diagonal.*

*Proof.* Let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be a  $\theta$ -separating cover of  $X$ . For each pair of positive integers  $n$  and  $k$  let  $\mathcal{H}_{nk} = \{H: H \neq \phi, H = \bigcap_{i=1}^k G_i, G_1, \dots, G_k \text{ distinct elements of } \mathcal{G}_n\}$  and let  $F_{nk} = X - \bigcup \{H: H \in \mathcal{H}_{nk}\}$ . Now  $F_{nk}$  is a closed set and so  $F_{nk} = \bigcap_{j=1}^\infty W_{nkj}$ , where each  $W_{nkj}$  is open. For  $j = 1, 2, \dots$  let  $\mathcal{K}_{nkj} = \mathcal{H}_{nk} \cup \{W_{nkj}\}$ . Then each  $\mathcal{K}_{nkj}$  is an open cover of  $X$  and the sequence  $\{\mathcal{K}_{nkj}: n, k, j \text{ in } N\}$  exhibits the  $G_\delta$ -diagonal property for  $X$ .

**PROPOSITION 3.3.** *Every  $\theta$ -refinable space with a  $G_\delta$ -diagonal has a  $\theta$ -separating cover.*

*Proof.* Let  $X$  be a  $\theta$ -refinable space and let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be open covers of  $X$  exhibiting the  $G_\delta$ -diagonal property for  $X$ . For each  $n$  in  $N$  let  $\mathcal{H}_{n1}, \mathcal{H}_{n2}, \dots$  be a  $\theta$ -refinement of  $\mathcal{G}_n$ . Then

$$\{\mathcal{H}_{nk}: n = 1, 2, \dots, k = 1, 2, \dots\}$$

is a  $\theta$ -separating cover of  $X$ .

The following lemmas, due to Burke and Miscenko [19], play a key role in the proof of our theorem. For the sake of completeness we sketch the proof of Burke's result. (See Remark 1.9 in [6]).

**LEMMA 3.4.** (Burke) *Let  $X$  be a regular,  $\theta$ -refinable  $w\Delta$ -space. Then there is a sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  of open covers of  $X$  such that for each  $x$  in  $X$ ,*

- (a)  $C_x = \bigcap_{n=1}^\infty \text{st}(x, \mathcal{G}_n)$  is compact;
- (b)  $\{\text{st}(x, \mathcal{G}_n): n = 1, 2, \dots\}$  is a base for  $C_x$ .

*Proof.* Let  $\mathcal{V}_1, \mathcal{V}_2, \dots$  be a  $w\Delta$ -sequence for  $X$ . By induction on  $n$  construct for each positive integer  $n$  a sequence  $\mathcal{W}_{n1}, \mathcal{W}_{n2}, \dots$  of open covers of  $X$  such that

- (1) for  $k = 1, 2, \dots, \{\bar{W}: W \text{ in } \mathcal{W}_{nk}\}$  refines  $\mathcal{V}_n$  and  $\mathcal{W}_{ij}$ ,  $1 \leq i \leq n-1, 1 \leq j \leq n-1$ ;

(2) for each  $x$  in  $X$  there is a  $k$  in  $N$  such that  $\text{ord}(x, \mathcal{W}_{nk})$  is finite.

For  $n = 1, 2, \dots$  let  $\mathcal{G}_n = \mathcal{W}_{n1}$ . Then the sequence  $\mathcal{G}_1, \mathcal{G}_2, \dots$  satisfies properties (a) and (b).

**LEMMA 3.5.** (Miščenko) *Let  $\mathcal{V}$  be a point-countable collection of subsets of a set  $X$  and let  $M$  be a subset of  $X$ . Then there are at most countably many finite minimal covers of  $M$  by elements of  $\mathcal{V}$ .*

We now state and prove the main result in this section.

**THEOREM 3.6.** *Let  $X$  be a regular,  $\theta$ -refinable  $w\Delta$ -space with a point-countable separating open cover. Then  $X$  is a Moore space.*

*Proof.* We are going to show that  $X$  has a  $\theta$ -separating cover and that every closed subset of  $X$  is a  $G_\delta$ . It follows by Proposition 3.2 that  $X$  has a  $G_\delta$ -diagonal and hence by Corollary 2.6  $X$  is a Moore space.

Let  $\mathcal{V}$  be a point-countable separating open cover of  $X$ . We assume that  $X \in \mathcal{V}$ , and hence for every subset  $M$  of  $X$  there is a finite subcollection of  $\mathcal{V}$  which covers  $M$ , namely  $\{X\}$ . Let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be open covers of  $X$  such that for each  $x$  in  $X$ ,

- (a)  $C_x = \bigcap_{n=1}^{\infty} \text{st}(x, \mathcal{G}_n)$  is compact;
- (b)  $\{\text{st}(x, \mathcal{G}_n) : n = 1, 2, \dots\}$  is a base for  $C_x$ .

For each  $n$  in  $N$  let  $\mathcal{H}_{n1}, \mathcal{H}_{n2}, \dots$  be a  $\theta$ -refinement of  $\mathcal{G}_n$ . Recall that

- (c)  $\mathcal{H}_{nk}$  refines  $\mathcal{G}_n$ ,  $k = 1, 2, \dots$ ;
- (d) for each  $x$  in  $X$  there is a  $k$  in  $N$  such that  $\text{ord}(x, \mathcal{H}_{nk})$  is finite.

$X$  has a  $\theta$ -separating cover. For each pair of positive integers  $n$  and  $k$  and for each  $H$  in  $\mathcal{H}_{nk}$  let  $H(n, k, 1), H(n, k, 2), \dots$  be all finite minimal covers of  $H$  by elements of  $\mathcal{V}$ , and let

$$\mathcal{K}_{nkj} = \{H \cap V : H \in \mathcal{H}_{nk}, V \in H(n, k, j)\}.$$

To show that  $\{\mathcal{K}_{nkj} : n, k, j \text{ in } N\}$  is a  $\theta$ -separating cover of  $X$ , let  $x$  and  $y$  be two distinct points of  $X$ . Choose  $V_1$  in  $\mathcal{V}$  such that  $x \in V_1$  and  $y \notin V_1$ , and let  $\{V_1, \dots, V_t\}$  be a finite cover of  $C_x$  by elements of  $\mathcal{V}$  such that  $x \notin V_i$  for  $i = 2, \dots, t$ . Now  $C_x \subseteq \bigcup_{i=1}^t V_i$  and so by (b) there is a  $n$  in  $N$  such that  $\text{st}(x, \mathcal{G}_n) \subseteq \bigcup_{i=1}^t V_i$ . Choose  $k$  in  $N$  such that  $\text{ord}(x, \mathcal{H}_{nk})$  is finite, and let  $H$  be some element of  $\mathcal{H}_{nk}$  such that  $x \in H$ . Since  $\mathcal{H}_{nk}$  refines  $\mathcal{G}_n$ ,  $H \subseteq \text{st}(x, \mathcal{G}_n)$

and so  $H \subseteq \bigcup_{i=1}^t V_i$ . Choose a minimal subcollection of  $\{V_1, \dots, V_t\}$  which covers  $H$  and label it  $H(n, k, j)$ . Note that  $V_1 \in H(n, k, j)$ . Thus  $(H \cap V_1) \in \mathcal{H}_{nkj}$ ,  $x \in (H \cap V_1)$ , and  $y \notin (H \cap V_1)$ . Finally, suppose  $H_1, \dots, H_r$  are all elements of  $\mathcal{H}_{nk}$  containing  $x$ . Since  $H_i(n, k, j)$  is finite for  $i = 1, \dots, r$  it follows that  $\text{ord}(x, \mathcal{H}_{nkj})$  is finite. This completes the proof that  $X$  has a  $\theta$ -separating cover.

*Every closed subset of  $X$  is a  $G_\delta$ .* Let  $M$  be a closed subset of  $X$ . For each pair of positive integers  $n$  and  $k$ , and for each  $H$  in  $\mathcal{H}_{nk}$  such that  $H \cap M \neq \emptyset$ , let  $H(n, k, j)$ ,  $j = 1, 2, \dots$  be all finite minimal covers of  $H \cap M$  by elements of  $\mathcal{V}$ . By repeatedly counting a cover if necessary, we may assume that  $H(n, k, j)$  exists for all  $j$  in  $N$ . For  $j = 1, 2, \dots$  let  $H^*(n, k, j)$  denote the union of all elements of  $H(n, k, j)$ , and let  $W_{nkj} = \bigcup \{H \cap (\bigcap_{i=1}^j H^*(n, k, i)) : H \in \mathcal{H}_{nk}, H \cap M \neq \emptyset\}$ . Clearly each  $W_{nkj}$  is open and contains  $M$ . To complete the proof that  $M$  is a  $G_\delta$  it suffices to show that if  $x \notin M$  then there exist  $n, k$ , and  $j$  such that  $x \notin W_{nkj}$ .

First suppose that  $C_x \cap M = \emptyset$ . Choose  $n$  in  $N$  such that  $\text{st}(x, \mathcal{G}_n) \cap M = \emptyset$ , and let  $k$  and  $j$  be any positive integers. Suppose  $x \in W_{nkj}$ . Then there is a  $H$  in  $\mathcal{H}_{nk}$  such that  $x \in H$  and  $H \cap M \neq \emptyset$ . Now  $\mathcal{H}_{nk}$  refines  $\mathcal{G}_n$  and so  $H \subseteq \text{st}(x, \mathcal{G}_n)$ . Hence  $\text{st}(x, \mathcal{G}_n) \cap M \neq \emptyset$  and this contradicts the choice of  $n$ .

Next suppose that  $C_x \cap M \neq \emptyset$ . Let  $\{V_1, \dots, V_t\}$  be a finite cover of  $C_x \cap M$  by elements of  $\mathcal{V}$  such that  $x \notin V_r$ ,  $r = 1, \dots, t$ . Choose  $n$  in  $N$  such that  $\text{st}(x, \mathcal{G}_n) \subseteq (\bigcup_{r=1}^t V_r) \cup (X - M)$ . Let  $k$  in  $N$  be such that  $\text{ord}(x, \mathcal{H}_{nk})$  is finite and let  $H_1, \dots, H_s$  be all elements of  $\mathcal{H}_{nk}$  which contain  $x$  and intersect  $M$ . For  $i = 1, \dots, s$ ,  $H_i \subseteq \text{st}(x, \mathcal{G}_n)$  and so  $H_i \cap M \subseteq \bigcup_{r=1}^t V_r$ . Select from  $\{V_1, \dots, V_t\}$  a minimal subcollection which covers  $H_i \cap M$  and label it  $H_i(n, k, j_i)$ . Now  $x \notin H_i^*(n, k, j_i)$  and so if we take  $j = \max\{j_1, \dots, j_s\}$  then  $x \notin W_{nkj}$ .

**4.  $\alpha$ -spaces.** A space with a  $\sigma$ -closure preserving separating closed cover is called a  $\sigma^*$ -space. This definition was introduced by Nagata and Siwiec in [21].

**PROPOSITION 4.1.** *Every subparacompact space with a  $G_\delta$ -diagonal is a  $\sigma^*$ -space.*

*Proof.* Let  $X$  be a subparacompact space and let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be open covers of  $X$  exhibiting the  $G_\delta$ -diagonal property for  $X$ . For each  $n$  in  $N$  let  $\mathcal{F}_{n1}, \mathcal{F}_{n2}, \dots$  be a  $\sigma$ -discrete closed refinement of  $\mathcal{G}_n$ . Then  $\{\mathcal{F}_{nk} : n = 1, 2, \dots, k = 1, 2, \dots\}$  is a  $\sigma$ -closure preserving

separating closed cover of  $X$ .

In [6] Burke showed that a regular  $w\mathcal{A}$ -space is a Moore space if and only if it is a  $\sigma^*$ -space. His method of proof suggests introducing a new class of spaces which we call  $\alpha$ -spaces. We shall show that  $\sigma^*$ -spaces are  $\alpha$ -spaces and that a regular  $w\mathcal{A}$ -space is a Moore space if and only if it is an  $\alpha$ -space.

**DEFINITION 4.2.** A space  $X$  is an  $\alpha$ -space if there is a function  $g$  from  $N \times X$  into the topology of  $X$  such that for each  $x$  in  $X$ ,

(a)  $\bigcap_{n=1}^{\infty} g(n, x) = \{x\}$ ;

(b) if  $y \in g(n, x)$  then  $g(n, y) \subseteq g(n, x)$ .

Such a function is called an  $\alpha$ -function for  $X$ .

**PROPOSITION 4.3.** Every  $\sigma^*$ -space is an  $\alpha$ -space.

*Proof.* Let  $\mathcal{F}_1, \mathcal{F}_2, \dots$  be a  $\sigma$ -closure preserving separating closed cover of a  $\sigma^*$ -space  $X$ . For  $n$  in  $N$  and  $x$  in  $X$  let

$$g(n, x) = X - \bigcup \{F \in \mathcal{F}_n : x \notin F\}.$$

It is easy to check that the function  $g$  is an  $\alpha$ -function for  $X$ .

**PROPOSITION 4.4.** Every space with a  $\sigma$ -point finite separating open cover is an  $\alpha$ -space. In particular, every  $T_1$  space with a  $\sigma$ -point finite base is an  $\alpha$ -space.

*Proof.* Let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be a  $\sigma$ -point finite separating open cover of a space  $X$ . We may assume that  $X \in \mathcal{G}_n$  for all  $n$  in  $N$ . For  $n = 1, 2, \dots$  and  $x$  in  $X$  let  $g(n, x) = \bigcap \{G \text{ in } \mathcal{G}_n : x \text{ in } G\}$ . Then the function  $g$  is an  $\alpha$ -function for  $X$ .

The following characterization of semi-stratifiable spaces will be useful in proving the main theorem in this section.

**LEMMA 4.5.** The following are equivalent for a space  $X$ :

(a)  $X$  is semi-stratifiable.

(b) There is a function  $g$  from  $N \times X$  into the topology of  $X$  such that (1) for each  $x$  in  $X$ ,  $\bigcap_{n=1}^{\infty} g(n, x) = \{x\}$ ; (2) if  $x \in g(n, x_n)$  for  $n = 1, 2, \dots$  then the sequence  $\langle x_n \rangle$  converges to  $x$ .

(c) There is a function  $g$  from  $N \times X$  into the topology of  $X$  such that (1) for each  $x$  in  $X$  and  $n$  in  $N$ ,  $x \in g(n, x)$ ; (2) if  $x \in g(n, x_n)$  for  $n = 1, 2, \dots$  then  $x$  is a cluster point of the sequence  $\langle x_n \rangle$ .

*Proof.* The equivalence of (a) and (b) is due to Creede [8], and

(b)  $\Rightarrow$  (c) is obvious. To complete the proof we show that (c)  $\Rightarrow$  (b). Thus, let  $g$  be a function satisfying (c), and assume that  $g(n+1, x) \subseteq g(n, x)$  for all  $n$  in  $N$  and  $x$  in  $X$ .

To prove (1) of (b), first let  $y \in \bigcap_{n=1}^{\infty} g(n, x)$ . Then by (2) of (c),  $y$  is a cluster point of the sequence  $\{x, x, \dots\}$  and so  $y \in \{x\}^-$ . Next let  $y \in \{x\}^-$ . Then  $x \in g(n, y)$  for  $n = 1, 2, \dots$  so by (2) of (c) it follows that  $x$  is a cluster point of the sequence  $\{y, y, \dots\}$ . Thus  $y \in g(n, x)$  for  $n = 1, 2, \dots$  and so  $y \in \bigcap_{n=1}^{\infty} g(n, x)$ .

To prove (2) of (b), let  $x \in g(n, x_n)$ ,  $n = 1, 2, \dots$  and suppose that the sequence  $\langle x_n \rangle$  does not converge to  $x$ . Then there is a neighborhood  $W$  of  $x$  and a subsequence  $\langle x_{n_k} \rangle$  of  $\langle x_n \rangle$  such that  $x_{n_k} \notin W$  for all  $k$  in  $N$ . Now  $x \in g(n_k, x_{n_k}) \subseteq g(k, x_{n_k})$  for  $k = 1, 2, \dots$  so by (2) of (c),  $x$  is a cluster point of the sequence  $\langle x_{n_k} \rangle$ . But this is impossible, and so we conclude that  $\langle x_n \rangle$  converges to  $x$ .

**THEOREM 4.6.** *A regular  $w\Delta$ -space is a Moore space if and only if it is an  $\alpha$ -space.*

*Proof.* By Propositions 4.1 and 4.3 every Moore space is an  $\alpha$ -space. To complete the proof let  $X$  be a regular  $w\Delta$ -space which is also an  $\alpha$ -space and let us show that  $X$  is a Moore space. By Corollary 2.6 it suffices to show that  $X$  is semi-stratifiable.

Let  $\mathcal{S}_1, \mathcal{S}_2, \dots$  be a  $w\Delta$ -sequence for  $X$ , let  $g$  be an  $\alpha$ -function for  $X$ . We may assume that for  $x$  in  $X$  and  $n$  in  $N$ ,  $g(n+1, x) \subseteq g(n, x)$ . For  $x$  in  $X$  and  $n = 1, 2, \dots$  let  $h(n, x) = g(n, x) \cap \text{st}(x, \mathcal{S}_n)$ . We shall show that the function  $h$  satisfies (c) of Lemma 4.5.

Clearly (1) of (c) is satisfied. To check (2) let  $x \in h(n, x_n)$  for  $n = 1, 2, \dots$ . Then for  $n = 1, 2, \dots$ ,  $x \in \text{st}(x_n, \mathcal{S}_n)$  and so  $x_n \in \text{st}(x, \mathcal{S}_n)$ . Thus the sequence  $\langle x_n \rangle$  has a cluster point  $y$ . Suppose  $y \neq x$ . Now  $\{y\} = \bigcap_{n=1}^{\infty} g(n, y)$  and so there is a  $k$  in  $N$  such that  $x \notin g(k, y)$ . Since  $y$  is a cluster point of  $\langle x_n \rangle$  there is a  $m \geq k$  such that  $x_m \in g(k, y)$ . Since  $g$  is an  $\alpha$ -function for  $X$ ,  $x_m \in g(k, y)$  implies  $g(k, x_m) \subseteq g(k, y)$ . But  $x \in h(m, x_m) \subseteq g(m, x_m) \subseteq g(k, x_m)$  and so  $x \in g(k, y)$ , a contradiction. Thus  $x = y$  and  $x$  is a cluster point of  $\langle x_n \rangle$ .

**COROLLARY 4.7.** *Every regular  $w\Delta$ -space with a  $\sigma$ -point finite separating open cover is a Moore space.*

**COROLLARY 4.8.** *Every regular countably compact space with a  $\sigma$ -point finite separating open cover is metrizable.*

**5. A generalization of semi-stratifiable and  $w\Delta$ -spaces.** Let  $X$  be a space and let  $g$  be a function from  $N \times X$  into the topology of

$X$  such that for all  $x$  in  $X$  and  $n$  in  $N$ ,  $x \in g(n, x)$ . Consider the following properties of the function  $g$ .

(A) If  $x \in g(n, x_n)$  and  $y_n \in g(n, x_n)$  for  $n = 1, 2, \dots$  then  $x$  is a cluster point of the sequence  $\langle y_n \rangle$ .

(B) If  $x \in g(n, x_n)$  and  $y_n \in g(n, x_n)$  for  $n = 1, 2, \dots$  then the sequence  $\langle y_n \rangle$  has a cluster point.

(C) If  $x_n \in g(n, x)$  for  $n = 1, 2, \dots$  then  $x$  is a cluster point of the sequence  $\langle x_n \rangle$ .

(D) If  $x_n \in g(n, x)$  for  $n = 1, 2, \dots$  then the sequence  $\langle x_n \rangle$  has a cluster point.

(E) If  $x \in g(n, x_n)$  for  $n = 1, 2, \dots$  then  $x$  is a cluster point of the sequence  $\langle x_n \rangle$ .

(F) If  $x \in g(n, x_n)$  for  $n = 1, 2, \dots$  then the sequence  $\langle x_n \rangle$  has a cluster point.

In [10] Heath proved that developable spaces can be characterized in terms of a function  $g$  satisfying (A), and similarly  $w\mathcal{A}$ -spaces can be characterized in terms of a function  $g$  satisfying (B). Clearly 1<sup>st</sup> countable spaces are characterized by (C), and (D) is precisely the definition of a  $q$ -space [18]. Finally, as proved in §4, semi-stratifiable spaces are characterized by a function  $g$  satisfying (E). These observations suggest introducing a new class of spaces, based on (F), which generalizes semi-stratifiable and  $w\mathcal{A}$ -spaces.

**DEFINITION 5.1.** A space  $X$  is a  $\beta$ -space if there is a function  $g$  from  $N \times X$  into the topology of  $X$  such that

(a) for all  $x$  in  $X$  and  $n$  in  $N$ ,  $x \in g(n, x)$ ;

(b) if  $x \in g(n, x_n)$  for  $n = 1, 2, \dots$  then the sequence  $\langle x_n \rangle$  has a cluster point.

Such a function is called a  $\beta$ -function for  $X$ .

**THEOREM 5.2.** The following are equivalent for a regular space  $X$ :

(a)  $X$  is semi-stratifiable.

(b)  $X$  is a  $\beta$ -space with a  $G^*_\delta$ -diagonal.

(c)  $X$  is an  $\alpha$ -space and a  $\beta$ -space.

*Proof.* Clearly (a)  $\Rightarrow$  (b) and (a)  $\Rightarrow$  (c). To prove (b)  $\Rightarrow$  (a) let  $g$  be a  $\beta$ -function for  $X$  and let  $\mathcal{G}_1, \mathcal{G}_2, \dots$  be a  $G^*_\delta$ -sequence for  $X$ , where it is assumed that  $\mathcal{G}_{n+1}$  refines  $\mathcal{G}_n$  for all  $n$ . For  $x$  in  $X$  and  $n$  in  $N$  let  $h(n, x) = g(n, x) \cap \text{st}(x, \mathcal{G}_n)$ . Then  $h$  satisfies (c) of Lemma 4.5 and so  $X$  is semi-stratifiable.

To prove (c)  $\Rightarrow$  (a) let  $g$  be a  $\beta$ -function for  $X$  and let  $h$  be an  $\alpha$ -function for  $X$ , where  $h(n+1, x) \subseteq h(n, x)$  for all  $n$  in  $N$  and  $x$

in  $X$ . For  $x$  in  $X$  and  $n = 1, 2, \dots$  let  $k(n, x) = g(n, x) \cap h(n, x)$ . Then  $k$  satisfies (c) of Lemma 4.5 and so  $X$  is semi-stratifiable.

REMARK 5.3. The implication (d)  $\Rightarrow$  (a) of Corollary 2.6 and Theorem 4.6 can be proved using the above theorem together with Creede's result that every regular semi-stratifiable  $w\Delta$ -space is a Moore space.

6. Summary. The relationship between some of the classes of spaces considered in this paper can be summarized in a diagram as follows.

---

Mathematical papers intended for publication in the *Pacific Journal of Mathematics* should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. The editorial "we" must not be used in the synopsis, and items of the bibliography should not be cited there unless absolutely necessary, in which case they must be identified by author and Journal, rather than by item number. Manuscripts, in duplicate if possible, may be sent to any one of the four editors. Please classify according to the scheme of Math. Rev. Index to Vol. 39. All other communications to the editors should be addressed to the managing editor, Richard Arens, University of California, Los Angeles, California, 90024.

50 reprints are provided free for each article; additional copies may be obtained at cost in multiples of 50.

---

The *Pacific Journal of Mathematics* is published monthly. Effective with Volume 16 the price per volume (3 numbers) is \$8.00; single issues, \$3.00. Special price for current issues to individual faculty members of supporting institutions and to individual members of the American Mathematical Society: \$4.00 per volume; single issues \$1.50. Back numbers are available.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley, California, 94708.
