CONTENT OF THE FRUSTUM OF A SIMPLEX

Mir Maswood Ali
CONTENT OF THE FRUSTUM OF A SIMPLEX

MIR M. ALI

In the Euclidean space of \( n \) dimensions, \( \mathbb{R}^n \), the \((n-1)\)-dimensional content of the portion of an \((n-1)\)-dimensional simplex contained in a semispace is evaluated. Also, in \( \mathbb{R}^n \), the content of the portion of an \( n \)-dimensional simplex contained in a semispace is evaluated.

More precisely, the following theorems are proved.

Set up a Cartesian coordinate system in \( \mathbb{R}^n \) and refer to a general point in the \( n \)-space by \((y_1, y_2, \ldots, y_n)\). Let \( S_n, S_{n-1} \) and \( H \) be defined as follows:

\[
S_n: \{(y_1, y_2, \ldots, y_n) | y_i \geq 0, i = 1, \ldots, n, \sum y_i \leq 1\}
\]

\[
S_{n-1}: \{(y_1, y_2, \ldots, y_n) | y_i \geq 0, i = 1, \ldots, n, \sum y_i = 1\}
\]

and

\[
H: \{(y_1, y_2, \ldots, y_n) | \sum a_i y_i \leq z\}
\]

Let \([f(x)|x = x_1, x_2, \ldots, x_{r+1}]\) denote the \( r \)th divided difference of \( f(x) \) with arguments for \( x \) as \( x_1, x_2, \ldots, x_{r+1} \). Define \( x_- = x \) if \( x < 0 \) and \( x_- = 0 \) if \( x \geq 0 \).

**Theorem 1.** The content of the frustum \( S_n \cap H \) expressed as a ratio of the content of \( S_n, C[S_n] \), say, \( C[S_n] = (n!)^{-1} \), is given by

\[
\frac{C[S_n \cap H]}{C[S_n]} = [((x - z)_-)^n | x = a_0, a_1, a_2, \ldots, a_n]
\]

where \( a_0 \) is defined by \( a_0 = 0 \).

**Theorem 2.** The \((n-1)\)-content of the frustum \( S_{n-1} \cap H \) expressed as a ratio of \( C[S_{n-1}] = \sqrt{n}/(n - 1)! \) is given by

\[
\frac{C[S_{n-1} \cap H]}{C[S_{n-1}]} = [((x - z)_-)^{n-1} | x = a_1, a_2, \ldots, a_n].
\]

An algorithm suitable for automatic computation of the divided differences occurring in the above theorems is discussed.

The result of Theorem 1 has applications (see Ali, 1969) to the statistical problem of the distribution of linear combination of ordered observations arising from a population uniformly distributed over \([0,
1] while the result of Theorem 2 may find application in linear programming and allocation theory.

G. Varsi [7] has considered the problem in Theorem 2 and by means of a successive dissection technique, he arrives at an algorithm suitable for automatic computation. It is shown that the formula of the present paper leads to the algorithm proposed by Varsi.

The evaluation of the divided differences occurring in the above theorems is discussed in §3. For numerical computation of these divided differences, an algorithm suitable for automatic computation is discussed in §4.

The particular choice of \( S_n \) and \( S_{n-1} \) in the above theorems does not involve any loss of generality as shown below.

Consider in \( R^n \) an \( n \)-simplex \( T_n \) whose vertices are \( V_i \) for \( i = 1, 2, \ldots, n+1 \). Let the co-ordinates of \( V_i \) referred to an \( n \)-dimensional cartesian co-ordinate system with origin at \( V_{n+1} \) be denoted by \( x_{i,1}, x_{i,2}, \ldots, x_{i,n} \) for \( i = 1, 2, \ldots, n \). Let \( \sigma_n \) denote the semispace given by \( \sigma_n: \{ (x_1, x_2, \ldots, x_n) | \sum c_i x_i \leq z \} \).

The frustum is defined by \( T_n \cap \sigma_n \) and let \( C[T_n \cap \sigma_n] \) denote its content.

Define the \( n \times n \) matrix \( V \) in double suffix notation as \( V = (v_{ij}) \). Let \( X' = (x_1, x_2, \ldots, x_n) \) and \( Y' = (y_1, y_2, \ldots, y_n) \). Then it is easily checked that the linear transformation from \( X \) to \( Y \) given by \( X = V' Y \) transforms \( T_n \) to the simplex \( S_n \) as defined in Theorem 1 and \( \sigma_n \) is transformed to \( H \) given by \( H: \{ (y_1, \ldots, y_n) | \sum a_i y_i \leq z \} \). Therefore, it follows that \( C[T_n \cap \sigma_n] = \| V \| C[S_n \cap H] \), with \( \sum c_i x_i = a_i \).

Likewise, in \( R^n \) let \( T_{n-1} \) denote an \( (n-1) \)-simplex. With origin not on the \( (n-1) \)-flat passing through \( T_{n-1} \), refer to the \( n \) vertices \( V_i \) for \( i = 1, \ldots, n \) with co-ordinates as before. Let \( \sigma_n \) be defined as before. Proceeding in an analogous manner as in the former case it is seen that

\[
C[T_{n-1} \cap \sigma_n] = \| V \| C[S_{n-1} \cap H]
\]

where \( a_i \) is defined exactly as in the former case.

2. Divided difference. For convenience we state some standard results on divided differences.

The \( r \)th divided difference of a function \( f(x) \) with arguments \( x = x_0, x_1, \ldots, x_r \) is defined as:

\[
[f(x) | x = x_0, x_1, \ldots, x_r] = \sum_{i=0}^{r} f(x_i) / \prod_{j=0}^{r} (x_i - x_j)
\]

\[
(1) = |A|/|B|
\]

where
\[ A = \begin{bmatrix} 1 & x_0 & x_0^2 & \cdots & x_0^{r-1} & f(x_0) \\ 1 & x_1 & x_1^2 & \cdots & x_1^{r-1} & f(x_1) \\ \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ 1 & x_r & x_r^2 & \cdots & x_r^{r-1} & f(x_r) \end{bmatrix} \]

and

\[ B = \begin{bmatrix} 1 & x_0 & x_0^2 & \cdots & x_0^r \\ 1 & x_1 & x_1^2 & \cdots & x_1^r \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ 1 & x_r & x_r^2 & \cdots & x_r^r \end{bmatrix} \]

when \( x_0, x_1, \cdots, x_r \) are distinct.

Finally, we state the following well-known result: (see Steffensen, [6, p. 19]). For integral \( r \),

\[ (2) \quad [x^{n+r} | x = a_0, a_1, \cdots, a_n] = \begin{cases} 0 & \text{if } -n \leq r < 0 \\ 1 & \text{if } r = 0 \\ \sum' a_0^{a_1^{a_2^{\cdots a_n}}} \text{ for } r > 0 \\ (r_0 + r_1 + \cdots + r_n = r) \end{cases} \]

where \( \sum' \) denotes the summation over all the distinct products with nonnegative integral exponents whose sum is \( r \).

For definitions of divided differences of \( f(x) \) with coincident arguments the reader is referred to, for example, Hildebrand [3, p. 40], Steffensen [6, p. 20] and Isaacson and Keller [4, p. 254].

3. Divided difference of \( \{(x-z)\}_r \). Consider the \( r \)th divided difference of \( \{(x-z)\}_r \) with possibly coincident arguments \( a_0, a_1, \cdots, a_r \) for \( x \). We rule out the trivial case when \( z = a_0 = a_1 = \cdots = a_r = 0 \). Suppose \( a_0, a_1, \cdots, a_r \) are relabelled as \( b_1, \cdots, b_s \), \( b_i \neq b_j \) for \( i \neq j \) where \( b_v \) is repeated \( p_v + 1 \) times \( p_v \geq 0, v = 1, 2, \cdots, s \), so that \( p_1 + p_2 + \cdots + p_s + s = r + 1 \). Taking appropriate limits of (1) (cf. Isaacson and Keller, [4, p. 254]) we obtain

\[
\left[ \{(x-z)\}_r \right| x = a_0, a_1, \cdots, a_r
= \frac{1}{\prod_{v=1}^s p_v!} \left[ \prod_{v=1}^s \frac{\partial^{p_v}}{\partial x^v} \right] \left[ \{(x-z)\}_r \right| x = b_1, \cdots, b_s
\]

where the divided difference on the right is given by (1).

Another alternative form of (3) is obtained by taking appropriate limit of \( |A|/|B| \) in (1), for which we refer to Ali (1969). For example:
\[
\left[\frac{(x - z)_-}{(x - z)_+}\right]^3 | x = c, c, c, d
\]
\[
= \begin{bmatrix}
1 & c & c^2 & 1 & c & c^2 \\
0 & 1 & 2c & 0 & 1 & 2c & 3c^2 \\
0 & 0 & 2 & 6(c - z)_- & 0 & 0 & 2 & 6c \\
1 & d & d^2 & (d - z)_- & 1 & d & d^2 & d^3
\end{bmatrix}.
\]

The following two special cases of coincident arguments are of interest.

(i) Decompose \(a_0, a_1, \ldots, a_r\) into disjoint sets

\[
S_i: \{a_v | a_v - z < 0\} \quad \text{and} \quad S^*_i: \{a_v | a_v - z \geq 0\}.
\]

Let the \(a_v\) belonging to \(S_i\) be renamed as \(\alpha_1, \alpha_2, \ldots, \alpha_J\) while those belonging to \(S^*_i\) be renamed as \(\beta_1, \beta_2, \ldots, \beta_K\) so that \(J + K = r + 1\). If \(\alpha_1, \ldots, \alpha_J\) are distinct (whether \(\beta_1, \ldots, \beta_K\) are distinct or not) we have

\[
\left[\frac{(x - z)_-}{(x - z)_+}\right]^r | x = a_0, a_1, \ldots, a_r
\]

\[
= \sum_{v=1}^J (\alpha_v - z)^r \left/ \sum_{j=1}^J (\alpha_v - \alpha_j) \sum_{k=1}^K (\alpha_v - \beta_k) \right. .
\]

Likewise, if \(a_0, a_1, \ldots, a_r\) are decomposed into \(S_2: \{a_v | a_v - z \leq 0\}\) and \(S^*_2: \{a_v | a_v - z > 0\}\) and the \(a_v\) belonging to \(S_2\) are relabelled as \(\alpha_1, \ldots, \alpha_J\) while those belonging to \(S^*_2\) are distinct, say \(\beta_1, \ldots, \beta_K\) then

\[
\left[\frac{(x - z)_-}{(x - z)_+}\right]^r | x = a_0, a_1, \ldots, a_r
\]

\[
= 1 - \sum_{v=1}^K (\beta_v - z)^r \left/ \prod_{j=1}^J (\beta_v - \alpha_j) \prod_{k=1}^K (\beta_v - \beta_k) \right. .
\]

The last step follows from the fact that

\[
\left[\frac{(x - z)_-}{(x - z)_+}\right]^r | x = a_0, a_1, \ldots, a_r = 1.
\]

4. Computation of divided differences of \(\left[\frac{(x - z)_-}{(x - z)_+}\right]^r\). Consider the \(r\)th divided difference of \(\left[\frac{(x - z)_-}{(x - z)_+}\right]^r\) with arguments for \(x = a_0, a_1, \ldots, a_r\). Let as before the set of \(a_v\) satisfying \(a_v - z < 0\) be relabelled as \(\alpha_1, \ldots, \alpha_J\) while the remaining \(a_v\) satisfying \(a_v - z \geq 0\) be relabelled as \(\beta_1, \ldots, \beta_K\), so that \(K + J = r + 1\).

Define

\[
A_{\lambda v} = \left[\frac{(x - z)_-}{(x - z)_+}\right]^{i+\lambda-1} | x = \alpha_1, \ldots, \alpha_i, \beta_1, \ldots, \beta_v
\]

Further let

\[
X_\lambda = \alpha_\lambda - z \quad \text{for} \quad \lambda = 1, \ldots, J
\]

and
\[ Y_\mu = \beta_\mu - z \quad \text{for} \quad \mu = 1, \ldots, K. \]

Then
\[ A_{j\mu} = [(X_{j+1})_{j+\mu-1} | X = X_1, \ldots, X_j, Y_1, \ldots, Y_\mu]. \]

Further by the use of (1) (temporarily assuming that \( \alpha_1, \ldots, \alpha_j, \beta_1, \ldots, \beta_\mu \) are distinct) the following recurrence relation is easily verified.
\[ A_{j\mu} = \frac{Y_\mu A_{(j-1)\mu - X_j A_{j((j-1)\mu)}}}{Y_\mu - X_j}. \]

It is readily checked from (1) with \( \text{[f(x)|x = a]} = f(a) \) that \( A_{j0} = 1 \) for \( \lambda = 1, 2, \ldots, J \) and \( A_{0\mu} = 0 \) for \( \mu = 1, 2, \ldots, K. \) Define \( A_{00} = 1. \)

The recurrence formula then gives \( A_{j\mu} = (X_j)/(X_j - Y_\mu) \) as it should be.

The above recurrence formula sets up an algorithm to compute successive values of \( A_{j\mu}. \) This algorithm was proposed by Varsi (from geometrical considerations) and is suitable for automatic computation. We note that

\[ \left[\left( (x - z) \right)^r | x = a_0, a_1, \ldots, a_r \right] = A_{JK}. \]

The Algorithm of Varsi.

Compute \( u_j = a_j - z \) for \( j = 0, 1, 2, \ldots, r. \) Label the \( u_j \) which are nonnegative as \( Y_1, \ldots, Y_K \) and the remaining \( u_j \) as \( X_1, \ldots, X_j \) so that \( K + J = r + 1. \)

The following notations are computational rather than mathematical notations.

**Step 1.** Set \( A_0 = 1, A_1 = A_2 = \cdots = A_K = 0. \)

**Step 2.** For each value of \( h \) repeat step 3 for \( h = 1, 2, \ldots, J. \)

**Step 3.**
\[ A_k \leftarrow \frac{Y_k A_k - X_k A_{k-1}}{Y_k - X_k} \quad \text{for} \quad k = 1, 2, \ldots, K. \]

(The expression on the right hand side is computed and stored in location \( A_k. \)) Then the quantity in \( A_K \) after the above set of operations is the value of \( \left[\left( (x - z) \right)^r | x = a_0, a_1, \ldots, a_r \right]. \)

It is to be noted that the above algorithm does not result in any indeterminacy for coincident values of \( a_0, a_1, \ldots, a_r \) since \( Y_\mu > X_k \) for all \( \lambda = 1, \ldots, J, \) and \( \mu = 1, \ldots, K. \)

5. Proof of the theorems. Consider the simplex \( L_a \) defined by
(4) \[ L_n: \{(x_1, x_2, \ldots, x_n) | \sum x_j \leq L \text{ and } x_j \geq 0, j = i, \ldots, n\} \]
and the semispace \( H \) defined by
\[ H: \{(x_1, x_2, \ldots, x_n) | a_1x_1 + \cdots + a_nx_n \leq z\}. \]

Temporarily assume that \( a_0, a_1, \ldots, a_n \) are distinct, where \( a_0 = 0 \). This restriction will be removed later.

Let
\[ F(z) = \frac{C[L_n \cap H]}{C[L_n]} = n! \int_{L_n \cap H} dx_1 \cdots dx_n. \]
It is easily shown that \( F(z) \) is a distribution function and that \( 0 \leq F(z) \leq 1 \).

Let the characteristic function (Fourier-Stiltjes transform) of \( F(z) \) be \( \phi(t) \), (see Loeve [5, p. 184]) where \( \phi(t) \) is defined by
\[ \phi(t) = \int_{-\infty}^{+\infty} e^{itx}dF(z). \]
It is easily seen that
\[ \phi(t) = \frac{n!}{L^n} \int_{L_n} e^{it(a_1y_1 + a_2y_2 + \cdots + a_ny_n)} dy_1 dy_2 \cdots dy_n. \]
Let \( x_i = Ly_i \) for \( i = 1, \ldots, n \).
Then we have
\[ \phi(t) = n! \int_{S_n} e^{it(a_1y_1 + \cdots + a_ny_n)} dy_1 dy_2 \cdots dy_n, \]
where \( S_n: y_1 + y_2 + \cdots + y_n \leq 1 \) and \( y_i \geq 0, i = 1, 2, \ldots, n \).

Straightforward computation shows that for integral values of \( r_1, r_2, \ldots, r_n \);
\[ n! \sum y_1^{r_1} y_2^{r_2} \cdots y_n^{r_n} dy_1 dy_2 \cdots dy_n = \frac{r_1!r_2! \cdots r_n!n!}{(n + r_1 + r_2 + \cdots + r_n)!} \]
so that by an easy computation we have
\[ \mu_r = \int_{-\infty}^{+\infty} z^r dF(z) = L^r \int_{S_n} (a_1y_1 + a_2y_2 + \cdots + a_ny_n)^r dy, \]
\[ = \frac{n!r!L^r}{(n + r)!} \sum' a_0^r a_1^{r_1} \cdots a_n^{r_n} \]
where \( \sum' \) is the sum of distinct products of nonnegative exponents whose sum is \( r \), with \( a_0 = 0 \).

Hence from (2) we obtain
\[ \mu'_r = \frac{n!r!L^r}{(n+r)!} [x^{n+r} | x = a_0, a_1, \ldots, a_n] \]
\[ = \frac{n!L^r}{(n+r)!} \left[ \frac{d^r x^{n+r}}{dx^r} \right]_{x=\xi} \] (cf. Steffensen p. 23)

where \( \xi \) is a number between the smallest and the largest of the numbers \( a_0, a_1, \ldots, a_n \). Hence \( |\mu'_r| \leq M^r L^r \), where \( M \) denotes the largest value of the numbers \( |a_0|, |a_1|, \ldots, |a_n| \), and for some \( c > 0 \),

\[ \left| \sum_{r=1}^{\infty} \frac{\mu'_r c^r}{r!} \right| \leq \sum_{r=0}^{\infty} \frac{L^r |Mc|^r}{r!} = e^{Lc|L} \]

which is finite for all values of \( c \). Therefore, the series \( \sum_{r=1}^{\infty} (\mu'_r c^r/r!) \) is absolutely convergent for all finite values of \( c > 0 \). Hence from a well-known theorem of Cramer [2], (for a proof see, for example, Wilks [8, p. 125]) we have

\[ \phi(t) = \sum_{r=0}^{\infty} \frac{\mu'_r}{r!} (it)^r \]
\[ = n! \sum_{r=0}^{\infty} \frac{(iLt)^r}{(n+r)!} [x^{n+r} | x = a_0, a_1, \ldots, a_n] \]
\[ = n! \sum_{r=0}^{\infty} \frac{(iLt)^{r-n}}{s!} [x^s | x = a_0, a_1, \ldots, a_n] \]

since \([x^s | x = a_0, a_1, \ldots, a_n] = 0 \) for \( s < n \), from (2).

Hence, we have

\[ \phi(t) = n!(iLt)^{-n} \sum_{s=0}^{n} \sum_{\nu=0}^{n} \frac{(iLt\alpha_{\nu})^s}{s!} \left[ \prod_{j=0}^{n} (a_\nu - a_j) \right] \]
\[ = n!(iLt)^{-n} \sum_{\nu=0}^{n} \frac{1}{\prod_{j=0}^{n} (a_\nu - a_j)} \sum_{s=0}^{n} \frac{(iLt\alpha_{\nu})^s}{s!} \]
\[ = n!(iLt)^{-n} \sum_{\nu=0}^{n} e^{iLt\alpha_{\nu}} \left[ \prod_{j=0}^{n} (a_\nu - a_j) \right]. \]

By the inversion formula (Loeve, [5, p. 186]) we obtain

\[ \frac{d}{dz} F(z) = \frac{n!}{2\pi} \int_{-\infty}^{\infty} (iLt)^{-n} \left[ \sum_{\nu=0}^{n} e^{iLt(a_{\nu}-z)} \left[ \prod_{j=0}^{n} (a_\nu - a_j) \right] \right] dt. \]

The above integral is analytic everywhere and the range of integration may be changed to the contour \( \Gamma \) consisting of the real axis from \(-\infty\) to \(-c\), the small semicircle with radius \( c \) with center at the origin and the real axis from \( c \) to \( \infty \).

Now by the use of
\[
\frac{1}{2\pi i^n} \int z^{-n} e^{i\alpha_n} dz = -(\alpha_\cdot)^{-1}/(n-1)!
\]

we have
\[
\left(\frac{d}{dz}\right) F(z) = -nL^{-n} \sum_{\nu=0}^{n} \{(La_\nu - x)_-\}^{-1}/\prod_{j=0, j\neq \nu}^{n} (a_\nu - a_j)
\]

and therefore integration over \( z \) yields
\[
F(z) = \sum_{\nu=0}^{n} \left\{ \left(\frac{(a_\nu - z)}{L}\right)_-^n \right\} \prod_{j=0, j \neq \nu}^{n} (a_\nu - a_j) + K
= \left[ \left(\frac{(x - z)}{L}\right)_-^n \right\} \left| x = a_0, a_1, a_2, \ldots, a_n \right] + K .
\]

It is easily verified that: for \( z/L < \min (\alpha_0, \alpha_1, \ldots, \alpha_n) \), \( L_n \cap H = \emptyset \), and hence \( F(z) = 0 \); since in this case
\[
\left[ \left(\frac{(x - z)}{L}\right)_-^n \right\} \left| x = a_0, a_1, \ldots, a_n \right] = 0 ,
\]
we immediately have \( K = 0 \), so that,
\[
F(z) = \left[ \left(\frac{(x - z)}{L}\right)_-^n \right\} \left| x = a_0, a_1, \ldots, a_n \right] .
\]

Hence substituting \( L = 1 \), Theorem 1 is proved for the case when \( a_0, a_1, \ldots, a_n \) are distinct.

The distance of the \((n-1)\) flat \( \sum \alpha_i = L \) from the origin is \( L/\sqrt{n} \). Consider the simplexes \( L_n, (L + \delta L)_n \) as defined in (3) and the semispace \( H \) as in (4). The elementary volume \( C[(L + \delta L)_n] - C[L_n] \) divided by \( \delta L/\sqrt{n} \) by letting \( \delta L \to 0 \) gives the \((n-1)\)-dimensional content of the portion of the simplex \( \sum x_i = L, x_i \geq 0 \) contained in \( H \). From (6) this volume is equal to \( \sqrt{n}(d/dL)C[L_n \cap H] \)
\[
= \sqrt{n} \left(\frac{d}{dL}\right)C(L_n)F(z) = \sqrt{n} \frac{d}{dL} \frac{L^n}{n!} F(z)
= \sqrt{n} \frac{d}{n! dL} \{(Lx - z)^n \left| x = a_0, a_1, \ldots, a_n \right. \} .
\]

A simple calculation shows that the last expression is equal to
\[
\frac{\sqrt{n}}{(n-1)!} \{(Lx - z)^{n-1} \left| x = a_1, a_2, \ldots, a_n \right. \} .
\]

Hence, setting \( L = 1 \), we finally obtain
\[
C[S_{n-1} \cap H] = \frac{\sqrt{n}}{(n-1)!} \{(x - z)^{n-1} \left| x = a_1, a_2, \ldots, a_n \right. \}
\]
so that
\[
\frac{C[S_{n-1} \cap H]}{C[S_{n-1}]} = \left[\left(\{(x - z)_-\}^{n-1} | x = a_1, a_2, \ldots, a_n\right)\right].
\]

Hence, Theorem 2 is established when the \(a_j\) are distinct.

The continuity theorem for the characteristic function along with the definition of divided differences for \(k\) coincident argument shows that (with the definition of the divided difference for coincident arguments) both Theorem 1 and Theorem 2 are also true for the case of coincident arguments with expressions for divided differences as given in §3. In particular, the algorithm discussed in §4, is not only suitable for numerical computation, but also can be applied in all cases since there is no indeterminacy for coincident arguments.

6. Asymptotic case. A sequence of real numbers \((c_{1n}, c_{2n}, \ldots, c_{nn})\) will be said to obey Condition \(C\) if the following is satisfied:

Condition \(C\):
\[
\lim_{n \to \infty} \max_{1 \leq j \leq n} (c_{jn} - \bar{c}_n)^2 / \sum_{v=1}^{n} (c_{vn} - \bar{c}_n)^2 = 0,
\]
where \(\bar{c}_n = (c_{1n} + c_{2n} + \cdots + c_{nn})/n\).

**THEOREM.** If the sequence \((c_{1n}, c_{2n}, \ldots, c_{nn})\) satisfies Condition \(C\),
\[
\lim_{n \to \infty} \left[\left(\{(x - z)_-\}^{n-1} | x = c_{1n}, \ldots, c_{nn}\right)\right] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-u^2/2} du
\]
where \(z = \bar{e}_n + [\sum_{i=1}^{n} (c_{in} - \bar{e}_n)^2/n(n + 1)]^{1/2} t\).

Before proving this general result we state the following result obtained from statistical considerations by Ali [1]:

**LEMMA.**
\[
\lim_{n \to \infty} \left[\left(\{(x - z)_-\}^{n} | x = a_0, a_1, \ldots, a_n\right)\right] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-u^2/2} du
\]
where \(a_0 = 0, \text{ and } \bar{a}_n = (a_0 + a_1 + \cdots + a_n)/(n + 1)\) and \(z = \bar{a}_n + [\sum_{i=0}^{n} (a_i - \bar{a}_n)^2/(n + 1)(n + 2)]^{1/2} t\) provided the sequence \(a_0, a_1, \ldots, a_n\) satisfies Condition \(C\).

Let us now consider \(\left[\left(\{(x - z)_-\}^{n-1} | x = a_1, \ldots, a_n\right)\right]\). Write \(c_i = a_i - a_0, i = 1, \ldots, n;\) so that \(c_i = 0\). It is readily checked that if the sequence \((a_1, \ldots, a_n)\) obeys Condition \(C\) so does the sequence \((c_1 = 0, c_2, \ldots, c_n)\). Straightforward application of the above Lemma shows that
\[
\lim_{n \to \infty} \left[ (x - z)^n \right]^{x = a_1, \ldots, a_n} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-u^2/2} du
\]
where \( \bar{a}_n = (a_1 + \cdots + a_n)/n \), and \( z = \bar{a}_n + \left[ \sum (a_i - \bar{a}_n)^2/n(n + 1) \right]^{1/2}t \).
This proves the theorem.

REFERENCES

Received March 29, 1972 and in revised form March 22, 1973. The author takes this opportunity to thank Professor J. Dugundji, editor of the Pacific Journal of Mathematics, for making the paper by Varsi available before publication and for his kind permission to use the paper. The author wishes to thank the referee for pointing out numerous typographical errors and for helpful suggestions which improved this paper considerably. This work was supported by a grant from the National Research Council of Canada.

The Supporting Institutions listed above contribute to the cost of publication of this Journal, but they are not owners or publishers and have no responsibility for its content or policies.

Mathematical papers intended for publication in the Pacific Journal of Mathematics should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Items of the bibliography should not be cited there unless absolutely necessary, in which case they must be identified by author and Journal, rather than by item number. Manuscripts, in duplicate if possible, may be sent to any one of the four editors. Please classify according to the scheme of Math. Rev. Index to Vol. 39. All other communications to the editors should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints are provided free for each article; additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966. Regular subscription rate: $48.00 a year (6 Vols., 12 issues). Special rate: $24.00 a year to individual members of supporting institutions.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 103 Highland Boulevard, Berkeley, California, 94708.

PUBLISHED BY PACIFIC JOURNAL OF MATHEMATICS, A NON-PROFIT CORPORATION

Printed at Kokusai Bunken Insatsusha (International Academic Printing Co., Ltd.), 270, 3-chome Totsuka-cho, Shinjuku-ku, Tokyo 160, Japan.

* C. R. DePrima California Institute of Technology, Pasadena, CA 91109, will replace J. Dugundji until August 1974.
