ON THE MAXIMAL NUMBER OF LINEARLY INDEPENDENT REAL VECTORS ANNIHILATED SIMULTANEOUSLY BY TWO REAL QUADRATIC FORMS

FRANK UHLIG
ON THE MAXIMAL NUMBER OF LINEARLY INDEPENDENT
REAL VECTORS ANNIHILATED SIMULTANEOUSLY
BY TWO REAL QUADRATIC FORMS

FRANK UHLIG

For a nonsingular pair of real symmetric (r.s.) matrices $S$ and $T$ the maximal number $m$ of lin. ind. vectors simultaneously annihilated by the associated quadratic forms is computed as a function of the real Jordan normal form of $S^{-1}T$. Conversely one can deduce which real Jordan normal form $S^{-1}T$ must have, if a specific $m$ is the maximal number of such vectors. Furthermore, two new conditions are found that assure $S$ and $T$ to be simultaneously diagonalizable by a real congruence transformation.

First we introduce the notions of Jordan blocks, real Jordan normal form and the canonical pair form for pairs of r.s. matrices.

DEFINITION 0.1. A square matrix of the form

$$
M = \begin{pmatrix}
\lambda & e & 0 \\
& \ddots & \ddots & \ddots \\
& & e \\
0 & & & \lambda
\end{pmatrix}
$$

is called a Jordan block of type (A), if for $k \geq 2$ we have $\lambda \in \mathbb{R}$ and $e = 1$, while for $k = 1$ we have $M = (\lambda)$ with $\lambda \in \mathbb{R}$. Such a matrix $M$ is called a Jordan block of type (B), if for $k \geq 4$ we have $\lambda = (a - b, b, a)$, $a, b \in \mathbb{R}$, $b \neq 0$ and $e = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, while for $k = 2$ we have $M = \begin{pmatrix} a - b \\ b \end{pmatrix}$ with $a, b \in \mathbb{R}$, $b \neq 0$. Jordan blocks will also be denoted by $J(\lambda, k)$ and $J(a, b, k)$, respectively.

Now we can state the real Jordan normal form theorem (see, e.g., Kowalski [2], p. 248).

THEOREM 0.1. Every real square matrix $A$ is similar over the reals to a matrix $J = \text{diag} (A_1, \cdots, A_l)$, in which each square block $A_i$ corresponds to an eigenvalue $\lambda_i$ of $A$. If this eigenvalue $\lambda_i$ is real, the associated $A_i$ is a Jordan block of type (A); if $\lambda_i = a + bi \in \mathbb{R}$, then $A_i$ is a Jordan block of type (B). This $J$ is called the real Jordan normal form of $A$. It is uniquely determined by $A$, except for the order of its Jordan blocks.
The final result to be quoted will be the canonical pair form theorem for nonsingular pairs of r.s. matrices, that is pairs $S$ and $T$ where $S$ is nonsingular.

**Theorem 0.2.** Let $S$ and $T$ be a nonsingular pair of r.s. matrices. Let $S^{-1}T$ have real Jordan normal form $\text{diag}(J_1, \cdots, J_r, J_{r+1}, \cdots, J_m)$, where $J_1, \cdots, J_r$ are Jordan blocks of type (A) corresponding to real eigenvalues of $S^{-1}T$ and $J_{r+1}, \cdots, J_m$ are Jordan blocks of type (B) for pairs of complex conjugate roots of $S^{-1}T$.

Then $S$ and $T$ are simultaneously congruent by a real congruence transformation to

$$\text{diag}(\varepsilon_1 E_1, \cdots, \varepsilon_r E_r, E_{r+1}, \cdots, E_m)$$

and

$$\text{diag}(\varepsilon_1 E_1 J_1, \cdots, \varepsilon_r E_r J_r, E_{r+1} J_{r+1}, \cdots, E_m J_m),$$

respectively, where $\varepsilon_i = \pm 1$ and $E_i$ denotes the square matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ of the same size as $J_i$ for $i = 1, \cdots, m$.

Canonical forms for a pair of r.s. matrices go back to Weierstraß and Kronecker. A list of references can be found in Uhlig [3], Theorem 0.4.

**Notation.** For $S$ symmetric we define $Q_S = \{ x \in \mathbb{R}^n | x'Sx = 0 \}$.

We will now state the main theorems that relate $m = \max \{ k | \text{there exist } k \text{ lin. ind. vectors in } Q_S \cap Q_T \}$ to the real Jordan normal form of $S^{-1}T$. 

**Theorem 1.** Let $S$ and $T$ be a nonsingular pair of r.s. $n \times n$ matrices. Let $J$ be the real Jordan normal form of $S^{-1}T$. If

(i) $J$ contains a Jordan block of dimension greater than 3, or
(ii) $J$ contains two Jordan blocks of dimension 3 each, or
(iii) $J$ contains one Jordan block of dimension 3 and one of dimension 2, or
(iv) $n > 3$ and $J$ contains a Jordan block of dimension 3 and 1-dimensional blocks else, but not all eigenvalues of $S^{-1}T$ are the same, or
(v) $J$ contains two 2-dimensional Jordan blocks which correspond to different eigenvalues of $S^{-1}T$ if both blocks are of type (A), then $Q_S \cap Q_T$ contains $n$ linearly independent vectors.

**Theorem 2.** Let $S$ and $T$ be a nonsingular pair of r.s. matrices of dimension $n$. Let $J$ be the real Jordan normal form of $S^{-1}T$. If
(vi) \( n > 3 \), \( J \) contains one 3-dimensional Jordan block, linear blocks else and all eigenvalues of \( S^{-1}T \) are the same while inertia \( S \neq (n - 1, 1, 0), (1, n - 1, 0) \); or

(vii) \( n > 3 \) and \( J \) contains \( k \geq 1 \) identical 2-dimensional Jordan blocks \( J(\lambda, 2) \) of type (A), linear blocks else for eigenvalues \( \mu_i (i = 2k + 1, \cdots, n) \) and the set
\[
\{ \varepsilon_1, \cdots, \varepsilon_k, \varepsilon_i(\mu_i - \lambda) | i > 2k \}
\]
contains positive as well as negative numbers, where the \( \varepsilon_i = \pm 1 \) are the constants in the canonical pair form of \( S \) and \( T \) (see Theorem 0.2), or

(viii) \( n > 3 \), \( J \) contains one 2-dimensional block \( J(a, b, 2) \) of type (B) and linear blocks else for eigenvalues \( \mu_i \), where not all \( \mu_i \) are the same or \( ^1 \) inertia \( S \neq (n - 1, 1, 0), (1, n - 1, 0) \), then \( Q_S \cap Q_T \) contains \( n \) linearly independent vectors. If

(vi) (a) condition (vi) holds, except that inertia \( S = (n - 1, 1, 0) \) or \( (1, n - 1, 0) \), or

(viii) (a) condition (viii) holds, except that all real eigenvalues \( \mu_i \) as defined in (viii) are the same and inertia \( S = (n - 1, 1, 0) \) or \( (1, n - 1, 0) \). Then \( Q_S \cap Q_T \) contains a maximum of \( n - 1 \) lin. indep. vectors only. If

(vii) (a) condition (vii) holds except that the set \( \{ \varepsilon_1, \cdots, \varepsilon_k, \varepsilon_i(\mu_i - \lambda) | i > 2k \} \) as defined in (vii) contains \( r \geq 0 \) zeroes \( \mu_{2k+1} - \lambda = \cdots = \mu_{2k+r} - \lambda = 0 \) and only positive or only negative numbers else, and \( \varepsilon_{2k+1} = \cdots = \varepsilon_{2k+r}, \) then \( Q_S \cap Q_T \) contains a maximum number of \( k \) lin. indep. vectors. If

(vii) (b) condition (vii) (a) holds except that not all \( \varepsilon_i \) are the same for \( 2k + 1 \leq i \leq 2k + r \), then \( Q_S \cap Q_T \) contains a maximum of \( k + r \) lin. indep. vectors. If

(ix) \( n > 1 \) and \( S \) and \( T \) can be simultaneously diagonalized by a real congruence transformation, then the maximal number \( k \) of lin. ind. vectors in \( Q_S \cap Q_T \) can be \( k = 0, 2, \cdots, n \) depending on \( S \) and \( T \).

Theorem 3 will treat \( n \)-dimensional r.s. matrix pairs for \( n \leq 3 \):

The following lemma is useful for the proofs of Theorems 1 and 2.

**LEMMA 1.** Let \( S \) and \( T \) be real symmetric matrices and \( A \) be a real nonsingular matrix.

Then
\[
\max \{ k \mid \text{there exist } k \text{ lin. ind. vectors in } Q_S \cap Q_T \} = \max \{ k \mid \text{there exist } k \text{ lin. ind. vectors in } Q_A S A \cap Q_A T A \}.
\]

\(^1\) This "or" does not mean "either ... or".
This is obvious if one observes that $Q_{A^*A} = A^{-1}(Q_s)$ for nonsingular $A$.

**Proof.** (Theorem 1) In view of the above lemma we may assume without loss of generality that $S$ and $T$ are in canonical pair form:

$$S = \text{diag}\left( \pm E_1, \ldots, \pm E_r, E_{r+1}, \ldots, E_m \right),$$
$$T = \text{diag}\left( \pm E_1J_1, \ldots, \pm E_rJ_r, E_{r+1}J_{r+1}, \ldots, E_mJ_m \right),$$

where $J_1, \ldots, J_r$ are Jordan blocks of type (A) and $J_{r+1}, \ldots, J_m$ are of type (B).

Having $S$ and $T$ in this form is very advantageous. For then we have $(e_i'Se_i)^2 + (e_i'Te_i)^2 \neq 0$ for at most $r + 2(m - r)$ unit vectors $e_i$. The reason is as follows:

For the Jordan block $J_1 = J(\lambda, k)$ of type (A) we have: if $k$ is even:

$$e_{k/2+1}'Ee_{k/2+1} = 0$$

and

$$e_{k/2+1}'EJ(\lambda, k)e_{k/2+1} = \lambda,$$

while for all other $i \leq k$: $e_i'Ee_i = e_i'EJ(\lambda, k)e_i = 0$, if $k$ is odd:

$$e_{k+1/2}'Ee_{k+1/2} = 1$$

and

$$e_{k+1/2}'EJ(\lambda, k)e_{k+1/2} = \lambda,$$

while for all other $i \leq k$: $e_i'Ee_i = e_i'EJ(\lambda, k)e_i = 0$. For the Jordan block $J_1 = J(a, b, k)(b \neq 0)$ of type (B) we have: if $k$ is divisible by 4: $e_i'Ee_i = e_i'EJ(a, b, k)e_i = 0$ for all $i \leq k$; while for a $k$ not divisible by 4 we have

$$e_{k/2}'Ee_{k/2} = 0, e_{k/2}'EJ(a, b, k)e_{k/2} = b; e_{k/2+1}'Ee_{k/2+1} = 0,$$

$$e_{k/2+1}'EJ(a, b, k)e_{k/2+1} = -b$$

and $e_i'Ee_i = e_i'EJ(a, b, k)e_i = 0$ for all other $i \leq k$.

The same argument holds for each of the Jordan blocks. So there are at most $r + 2(m - r)$ unit vectors not simultaneously annihilated by the two quadratic forms $x'Sx$ and $x'Tx$ if $S$ and $T$ are in canonical pair form. For all $i$ such that $e_i \in Q_s \cap Q_T$ we will exhibit lin. ind. vectors $y_i \in Q_s \cap Q_T$ that have a nonzero $i$th component and hence are also lin. ind. of all $e_i$ with $e_i \in Q_s \cap Q_T$. Then Theorem 1 is proved: There are $n$ lin. ind. vectors in $Q_s \cap Q_T$.

The remainder of this proof will consist of finding these vectors $y_i$, one for each Jordan block of type (A), two for each Jordan block of type (B) of dimension not divisible by 4 in each of the cases (i), \dots, (v).

From now on we will in general assume that the Jordan blocks
of $S^{-1}T$ mentioned in (i), ..., (v) appear in the first diagonal positions. Before starting on the individual cases we express the quadratic forms corresponding to $S$ and $T$ by only singling out the first block here: If a Jordan block $J(\lambda, k) = J_1$ of type (A) appears first, let us look at the two quadratic forms $F(x) = x' S x$ and $G(x) = x' T x$.

For

$$S = \text{diag} (\pm E_1, \ldots, \pm E_m) \quad \text{and} \quad x = (x_1, \ldots, x_n)$$

we have

$$F(x) = \pm h(x) + f(x),$$

where

$$h(x) = x' \text{diag} (E_1, 0, \ldots, 0)x = \sum_{i+j=k+1} x_i x_j$$

and

$$f(x) = x' \text{diag} (0, \pm E_2, \ldots, \pm E_m)x$$

is a quadratic form involving $x_{k+1}, \ldots, x_n$ only.

For

$$T = \text{diag} (\pm E_1 J_1, \ldots, \pm E_m J_m)$$

we have

$$G(x) = \pm (\lambda h(x) + e(x)) + g(x)$$

where $h$ is as above,

$$e(x) = \sum_{i+j=k+2} x_i x_j \quad \text{for} \quad i, j \leq k$$

and

$$g(x) = x' \text{diag} (0, \pm E_2 J_2, \ldots, \pm E_m J_m)x$$

involves $x_{k+1}, \ldots, x_n$ only.

Now $F(x) = 0$ iff $f(x) = \mp h(x)$. And by definition $x \in Q_S \cap Q_T$ iff $F(x) = G(x) = 0$ hence iff

$$\text{(1)} \quad \pm e(x) + g(x) - \lambda f(x) = 0 \quad \text{and} \quad F(x) = 0.$$  

If a Jordan block $J(a, b, k) = J_1(b \neq 0)$ of type (B) appears first in $S^{-1}T$, then we define $F(x) = x' S x = h(x) + f(x)$ with $h$ and $f$ as above and $G(x) = x' T x = ah(x) + bt(x) + u(x) + g(x)$, where $h$ and $g$ are as above and

$$u(x) = \sum_{\substack{i+j=k+3 \\text{odd} \\text{or} \text{even} \\text{or} \text{even}}} x_i x_j, \quad \text{while} \quad t(x) = \sum_{\substack{i+j=k \\text{odd} \\text{or} \text{even}}} x_i x_j.$$

Thus in this case $x \in Q_S \cap Q_T$ iff $F(x) = G(x) = 0$, hence iff
(i): Assume (i) holds with a Jordan block $J(\lambda, k)$ of type (A) for $k \geq 4$. Then from above there is an $i$, $2 < i < k$, such that $e_i \in Q_S \cap Q_T$. For this index $i$ we define $\alpha_i, \beta_i \in \mathbb{R}$ and $y_i = \alpha_i e_i + \beta_i e_k + e_i$ such that (1) holds: $\pm e(y_i) + g(y_i) - \lambda f(y_i) = \pm (2\beta_i + e(e_i)) = 0$ determines $\beta_i$ and $F(y_i) = 0$ determines $\alpha_i$.

For $i > k$ such that $e_i \in Q_S \cap Q_T$ and $g(e_i) - \lambda f(e_i) = 0$, we define the vector $y_i = \alpha_i e_i + e_k + e_i$, where $\alpha_i$ is such that $F(y_i) = 0$. In the case that $g(e_i) - \lambda f(e_i) \neq 0$ we define $y_i = \alpha_i e_i + \beta_i e_k + e_i$, where $\alpha_i, \beta_i \in \mathbb{R}$ are such that (1) holds: $\pm (2\beta_i + g(e_i)) - \lambda f(e_i) = 0$ defines $\beta_i$ and $F(y_i) = 0$ defines $\alpha_i$.

Next assume (i) holds for a Jordan block $J(a, b, k)$ of type (B) for $k = 2l \geq 4$.

First assume $k = 2l$ is divisible by 4. Then $e_i \in Q_S \cap Q_T$ implies $i > k$ as pointed out above. For such an $i$ define $y_i = \alpha_i e_i + \beta_i e_l + e_{l+1} + e_i$ where $\alpha_i, \beta_i \in \mathbb{R}$ are such that (2) holds. When checking (2), note that $l$ is even, if $k$ is divisible by 4. $2b\alpha_i + g(e_i) - \lambda f(e_i) = 0$ defines $\alpha_i$ and $2\beta_i + h(e_i) = 0$ defines $\beta_i$.

Now assume $k = 2l$ is not divisible by 4. Then $l$ is odd and we know that both $e_i, e_{i+1} \in Q_S \cap Q_T$ from the above. If we define

$$y_i = e_i - \frac{b}{2}e_{i+3} \quad \text{and} \quad y_{i+1} = e_{i+1} + \frac{b}{2}e_{i+2},$$

then (2) holds for these two vectors. For $i > k$ such that $e_i \in Q_S \cap Q_T$ we define as before for the real case $y_i = \alpha_i e_i + e_k + e_i$ if $g(e_i) - \lambda f(e_i) = 0$ and $y_i = \alpha_i e_i + \beta_i e_k + e_k + e_i$ otherwise. This proves (i) of Theorem 1.

(ii): Assume $J$ contains two Jordan block of dimensions 3 each. Then these must be Jordan blocks of type (A); $J(\lambda, 3)$ and $J(\mu, 3)$ for $\lambda, \mu \in \mathbb{R}$. Define for $x = (x_1, \ldots, x_6)$:

$$F(x) = x'Sx = \varepsilon(2x_1x_6 + x_3^2) + \delta(2x_4x_5 + x_2^2) + f(x)$$

and

$$G(x) = x'Tx = \varepsilon(\lambda(2x_1x_6 + x_3^2) + 2x_2x_4) + \delta(\mu x_4x_5 + x_2^2) + 2x_5x_6 + g(x),$$

where $f$ and $g$ are quadratic forms not involving $x_1, \ldots, x_6$ and $\varepsilon, \delta = \pm 1$, independently from the canonical pair form.

Now $e_3, e_5 \in Q_S \cap Q_T$. And for these indices define the vectors $y_5 = -1/2e_5 - \delta e_3 + e_4 - 1/2e_4 + e_6 + e_5$ and $y_6 = -1/2e_6 - \delta e_3 + e_3 + 1/2e_4 - e_5 - e_6$. They are lin. ind. and satisfy $F(y_5) = G(y_5) = 0$ in (3). For $i > 6$ such that $e_i \in Q_S \cap Q_T$ we define
where $\beta_i$ is chosen such that
$$2\varepsilon\beta_i + g(e_i) - \lambda f(e_i) = 0,$$
and $\alpha_i$ is such that
$$F(y_i) = \varepsilon(2\alpha_i + \beta_i) + f(e_i) = 0.$$ Then $G(y_i) = 0$, too.
This completes (ii).

(iii): Here again the 3-dimensional Jordan block has to be of type (A): $J(\lambda, 3)$, while the 2-dimensional block can be of either type. Let for $x = (x_1, \ldots, x_n)$,
$$F(x) = x' S x = \varepsilon(2x_1 x_3 + x_5^2) + \delta(2x_4 x_5) + f(x)$$
and
$$G(x) = x' T x = \varepsilon(\lambda(2x_1 x_3 + x_5^2) + 2x_2 x_3)
+ \delta\left(\frac{2\mu x_4 x_5 + x_5^2}{2ax_4 x_5 + b(x_4^2 - x_5^2)}\right) + g(x)$$
in case of (A)
$$+ \delta\left(\frac{2\mu x_4 x_5 + x_5^2}{2ax_4 x_5 + b(x_4^2 - x_5^2)}\right) + g(x)$$
in case of (B)
where $\delta, \varepsilon = \pm 1$ from the canonical pair form and $f$ and $g$ do not involve the first five components. If the 2-dimensional Jordan block in question is of type (A), then for $i \leq 5$ we have $e_i \notin Q_S \cap Q_T$ exactly for $i = 2, 5$, while for a Jordan block of type (B) those indices are $i = 2, 4, 5$.
In case of (A) define
$$y_2 = \delta \varepsilon e_1 + e_2 - \frac{\delta \varepsilon}{2} e_3 + e_5$$
$$y_5 = \delta \varepsilon e_1 + e_2 - \frac{\delta \varepsilon}{2} e_3 - e_5$$
and one has $y_2, y_5 \in Q_S \cap Q_T$.
In case of a 2-dimensional block $J(a, b, 2)$, $b \neq 0$ of type (B), define
$$y_2 = -\frac{\varepsilon}{b} e_1 + e_2 + \frac{b}{2} e_3 + e_5$$
$$y_4 = +\frac{\varepsilon}{b} e_1 + e_2 - \frac{b}{2} e_3 + e_4$$
$$y_5 = -\frac{\varepsilon}{b} e_1 + e_2 + \frac{b}{2} e_3 - e_5.$$ Then $y_2, y_4, y_5 \in Q_S \cap Q_T$. 

For \( i > 5 \) such that \( e_i \in Q_S \cap Q_T \), define \( y_i = \alpha_i e_i + \beta_i e_2 + e_3 + e_i \), where \( \alpha_i, \beta_i \in \mathbb{R} \) are such that \( 2\varepsilon \beta_i + \gamma_i e_i - \lambda f(e_i) = 0 \) and \( F(y_i) = 0 \). This concludes part (iii).

(iv): Here we have \( F(x) = x'Sx = \varepsilon(2x_1x_4 + x_2) + f(x) \) and \( G(x) = x'Tx = \varepsilon(\lambda(2x_1x_3 + x_2) + 2x_2x_3) + g(x) \) and \( F(x) = G(x) = 0 \) iff

\[
\varepsilon 2x_1x_3 + g(x) - \lambda f(x) = 0 \quad \text{and} \quad F(x) = 0.
\]

By assumption all but the first Jordan block \( J(\lambda, 3) \) in \( S^{-1}T \) are 1-dimensional blocks \( J(\mu, 1) \). We assume \( n > 3 \), so there exists an \( i_0 > 3 \) such that \( g(e_{i_0}) - \lambda f(e_{i_0}) \neq 0 \), for \( g(e_{i_0}) - \lambda f(e_{i_0}) = \pm (\mu_{i_0} - \lambda) = 0 \) for all \( i > 3 \) contradicts our assumption.

Now \( e_i \in Q_S \cap Q_T \) and we define \( y_2 = \alpha e_1 + \beta e_2 + e_3 + e_4 \), where \( \beta_2 \neq 0 \) is such that \( 2\varepsilon \beta_2 + \gamma_2 e_3 - \lambda f(e_3) = 0 \) and \( \alpha_2 \) is such that \( F(y_2) = 0 \). For all \( i > 3 \) we have \( e_i \in Q_S \cap Q_T \) and we define \( y_{i_0} = -\alpha e_i - \beta e_2 - e_3 + e_i \) and \( y_k = \alpha e_1 + \beta e_2 + e_3 + e_i \) for all other \( i > 3 \), where the \( \alpha \)'s and \( \beta \)'s are chosen such that (4) holds for all \( y_i \). These \( n \) vectors \( y_i \) are lin. ind.

(v): Now only (v) remains to be proved. Let us first assume that the two 2-dimensional Jordan blocks in question are both of type (A): \( J(\lambda, 2), J(\mu, 2) \), where by assumption \( \lambda \neq \mu \). Then \( F(x) = x'Sx = \varepsilon 2x_1x_3 + \delta 2x_2x_4 + f(x) \) and \( G(x) = x'Tx = \varepsilon(\lambda(2x_1x_3 + x_2) + \delta(2\mu x_2x_4 + x_1^2) + g(x) \) where \( \varepsilon, \delta = \pm 1 \) and \( f \) and \( g \) do not involve the first four components of \( x \). Then \( F(x) = G(x) = 0 \) is equivalent to

\[
F(x) = 0 \quad \text{and} \quad 2\varepsilon \delta(\mu - \lambda)x_2x_4 + \varepsilon x_2^2 + \delta x_1^2 + g(x) - \lambda f(x) = 0.
\]

Now if \( e_i \in Q_S \cap Q_T \), then \( i = 2 \) or \( i = 4 \), unless \( i > 4 \). We define

\[
y_2 = \alpha e_1 + 2e_2 + \beta e_4 - e_i \\
y_4 = \alpha e_1 + 2e_2 + \beta e_4 + e_i
\]

and

\[
y_i = \alpha_i e_1 + \gamma_i e_2 + \beta_i e_4 + e_i + e_i
\]

gfor all \( i > 4 \) with \( e_i \in Q_S \cap Q_T \). Here \( \gamma_i \neq 0 \) are chosen such that \( \varepsilon \gamma_i + \delta + g(e_i) - \lambda f(e_i) \neq 0 \) while the \( \alpha \)'s and \( \beta \)'s are chosen such that (5) holds.

Next assume, the two 2-dimensional blocks are both of type (B): \( J(a, b, 2), J(c, d, 2) \) where \( b, c \neq 0 \).

Then \( F(x) \) is as above with \( \varepsilon = \delta = 1 \) while

\[
G(x) = x'Tx = 2ax_1x_2 + 2cx_3x_4 + b(x_1^2 - x_2^2) + d(x_3^2 - x_4^2) + g(x),
\]

and \( F(x) = G(x) = 0 \) is equivalent to
Here we have $e_i \in Q_S \cap Q_T$ for all $i \leq 4$.

If $bd > 0$ we define the following four lin. ind. vectors

\begin{align*}
y_1 &= \alpha e_1 + \beta e_4, \quad y_2 = \alpha e_1 - \beta e_4, \\
y_3 &= \alpha e_2 + \beta e_4, \quad y_4 = \alpha e_2 - \beta e_4,
\end{align*}

where $\alpha, \beta \neq 0$ are such that $b\alpha^2 - d\beta^2 = 0$ and thus (6) holds for all $y_i, i \leq 4$.

In $bd < 0$, we define $y_i$ as follows:

\begin{align*}
y_1 &= \alpha e_1 + \beta e_3, \quad y_2 = \alpha e_1 - \beta e_3, \\
y_3 &= \alpha e_2 + \beta e_3, \quad y_4 = \alpha e_2 - \beta e_3,
\end{align*}

where $\alpha, \beta \neq 0$ satisfy $b\alpha^2 + d\beta^2 = 0$ such that all four $y_i$ satisfy (6) again.

For indices $i > 4$ such that $e_i \in Q_S \cap Q_T$ we define the corresponding vector $y_i$ as follows:

If $f(e_i) = 0$ and $bd > 0$, let $y_i = \alpha_i e_1 + \beta_i e_3 + e_i$, where $\alpha_i, \beta_i$ are chosen such that $b\alpha_i^2 - d\beta_i^2 = -g(e_i)$. If $f(e_i) = 0$ and $bd < 0$, let $y_i = \alpha_i e_1 + \beta_i e_3 + e_i$, where $\alpha_i, \beta_i \in R$ such that $b\alpha_i^2 + d\beta_i^2 = -g(e_i)$. If $f(e_i) \neq 0$ and $g(e_i) - af(e_i) = 0$, then let $y_i = \alpha_i e_1 + \beta_i e_3 + e_i$ where $|\alpha_i| = |\beta_i|$ such that $y_i$ satisfies (6). If $f(e_i) \neq 0$ and $(g(e_i) - af(e_i))d > 0$, let $y_i = \alpha_i e_1 + \beta_i e_3 + \gamma_i e_4 + e_i$, where $|\alpha_i| = |\beta_i|$ and $\gamma_i$ are chosen such that (6) holds. If $f(e_i) \neq 0$ and $(g(e_i) - af(e_i))d < 0$, let $y_i = \alpha_i e_1 + \beta_i e_3 + \gamma_i e_4 + e_i$, with $\alpha_i, \beta_i, \gamma_i$ chosen to satisfy (6).

Finally we prove (v) for a Jordan block of type (A) and one of type (B): $J(\lambda, 2), J(\alpha, b, 2)$. Then $F(x)$ is as above with $\varepsilon = \pm 1$, $\delta = 1$ while $G(x) = ax'Tx = \varepsilon(2\lambda x_1 x_2 + x_2^2) + 2ax_4 x_i + b(x_3^2 - x_i^2) + g(x)$ where $g(x)$ does not involve $x_1, \ldots, x_4$. And $F(x) = G(x) = 0$ is equivalent to:

\begin{align*}
F(x) &= 0 \quad \text{and} \quad 2(a - \varepsilon\lambda)x_1 x_2 + \varepsilon x_2^2 + b(x_3^2 - x_i^2) \\
&\quad + g(x) - \lambda f(x) = 0.
\end{align*}

If $e_i \in Q_S \cap Q_T$, then $i = 2, 3, 4$ or $i > 4$. We define $y_2$ and $y_3$ first:

\begin{align*}
y_2 &= e_2 + \beta e_3 + \gamma e_4, \\
y_3 &= e_2 - \beta e_3 - \gamma e_4,
\end{align*}

where $\beta = \sqrt{-\varepsilon/b}$, $\gamma = 0$, if $\varepsilon \cdot b < 0$ and $\beta = 0$, $\gamma = \sqrt{\varepsilon/b}$, if $\varepsilon b > 0$. Then $e_i, y_2$, and $y_3$ are all lin. ind. and satisfy (7).

If $y_i$ has all of its first four components nonzero it will be lin. ind. of $e_i, y_2, y_3$ and all $e_i$ for $i > 4$. So let $y_i = \alpha e_1 + \beta e_2 + \gamma e_3 + \rho e_4 + 2(c - a)x_1 x_2 + b(x_3^2 - x_i^2) + g(x) - af(x) = 0$.

Here we have $e_i \in Q_S \cap Q_T$ for all $i \leq 4$. If $bd > 0$ we define the following four lin. ind. vectors

\begin{align*}
y_1 &= \alpha e_1 + \beta e_4, \quad y_2 = \alpha e_1 - \beta e_4, \\
y_3 &= \alpha e_2 + \beta e_4, \quad y_4 = \alpha e_2 - \beta e_4,
\end{align*}

where $\alpha, \beta \neq 0$ are such that $b\alpha^2 - d\beta^2 = 0$ and thus (6) holds for all $y_i, i \leq 4$.

In $bd < 0$, we define $y_i$ as follows:

\begin{align*}
y_1 &= \alpha e_1 + \beta e_3, \quad y_2 = \alpha e_1 - \beta e_3, \\
y_3 &= \alpha e_2 + \beta e_3, \quad y_4 = \alpha e_2 - \beta e_3,
\end{align*}

where $\alpha, \beta \neq 0$ satisfy $b\alpha^2 + d\beta^2 = 0$ such that all four $y_i$ satisfy (6) again.
\(\eta e_i\) where \(\alpha, \beta, \gamma, \eta\) are chosen as follows:

If \(a - \varepsilon \lambda = 0\), take \(\gamma = 1, \eta = 2, \beta = \sqrt{3b\varepsilon}\), if \(\varepsilon b > 0\) and \(\alpha \neq 0\) such that \(F(y_i) = 0\); but if \(\varepsilon b < 0\), choose \(\gamma = 2, \eta = 1, \beta = \sqrt{-3b\varepsilon}\) and \(\alpha\) as above, and \(y_i\) satisfies (7).

If \(a - \varepsilon \lambda \neq 0\), choose \(\eta \neq 0, \gamma = 1/\eta\) such that

\[
2(a - \varepsilon \lambda) + b\left(\frac{1}{\eta^2} - \eta^2\right) < 0 \quad \text{if } \varepsilon = 1
\]

and

\[
2(a - \varepsilon \lambda) + b\left(\frac{1}{\eta^2} - \eta^2\right) > 0 \quad \text{if } \varepsilon = -1.
\]

Then choose \(\beta \neq 0\) such that the second equation in (7) holds and after letting \(a = -\varepsilon/\beta\) the vector \(y_i\) again satisfies (7). For \(i > 4\) define \(y_i = \alpha e_i + e_2 + \beta e_3 + \gamma e_i + e_i\) where \(\alpha \in \mathbb{R}\) and either \(\beta = 0\) or \(\gamma = 0\) as before in such a way that (7) holds for each \(y_i, i > 4\). This completes the proof of Theorem 1.

We now go on to prove Theorem 2

Proof. (Theorem 2) We use the notation of the previous proof

(vi), (vi)(a): Let (vi) or (vi)(a) hold. Then the 3 dimensional Jordan block is of type (A): \(J(\lambda, 3)\). And we have with \(x = (x_1, \cdots, x_n)\)

\[
F(x) = x'Sx = \varepsilon_1(2x_1x_3 + x_3) + \sum_{i=4}^n \varepsilon_i x_i^2
\]

and

\[
G(x) = x'Tx = \varepsilon_1(\lambda(2x_1x_3 + x_3^2) + 2x_2x_3) + \sum_{i=4}^n \varepsilon_i \lambda x_i^2,
\]

where \(\varepsilon_i = \pm 1\). Hence \(F(x) = G(x) = 0\) is equivalent to \(F(x) = 0\) and \(x_2x_3 = 0\).

If all \(\varepsilon_i\) are the same, then, since inertia \(E_{3x3} = (2, 1, 0)\), we have inertia \(S = (n - 1, 1, 0)\) or \((1, n - 1, 0)\) and (vi)(a) would hold. But let us first assume (vi) holds. Then for some \(l \geq 4\) we must have \(\varepsilon_i \cdot \varepsilon_i < 0\). Clearly \(e_1, e_3 \in Q_S \cap Q_T\) and for the other indices we define:

\[
y_2 = e_2 + e_l
\]

\[
y_i = \frac{\varepsilon_i \varepsilon_i}{2} e_1 - e_3 + e_i \quad \text{for } i \geq 4.
\]
Then $e_1, e_3, y_2$ and $y_i (i \geq 4)$ are in $Q_S \cap Q_T$ and are lin. ind.

If (vi) (a) holds, then $F(x) = 0$ and $x_2 x_3 = 0$ implies $x_2 = 0$, such that we cannot find a vector $y_i \in Q_S \cap Q_T$ with a nonzero second component. Hence $Q_S \cap Q_T$ contains at most $(n - 1)$ lin. ind. vectors. But $e_1, e_3, y_i (i \geq 4)$ defined above are linearly independent and belong to $Q_S \cap Q_T$. This proves (vi) and (vi)(a).

(vii), (vii)(a), (vii)(b): We define

$$F(x) = x' S x = 2 \sum_{i=1}^{k} \epsilon_i x_{2i-1} x_{2i} + \sum_{i=2k+1}^{n} \epsilon_i x_i^2$$

and

$$G(x) = x' T x = 2\lambda \sum_{i=1}^{k} \epsilon_i x_{2i-1} x_{2i} + \sum_{i=1}^{k} \epsilon_i x_i^2 + \sum_{i=2k+1}^{n} \epsilon_i (\mu_i - \lambda) x_i^2,$$

where $\epsilon_i = \pm 1$. Thus $F(x) = G(x) = 0$ is equivalent to $F(x) = 0$ and

$$\sum_{i=1}^{k} \epsilon_i x_i^2 + \sum_{i=2k+1}^{n} \epsilon_i (\mu_i - \lambda) x_i^2 = 0 .$$

Assuming (vii) holds, then the quadratic form in (8) is indefinite, so there must exist an index $l$ such that

$$\epsilon_l \epsilon_i (\mu_i - \lambda) < 0 \quad \text{for some } l \geq 2k + 1$$

or such that

$$\epsilon_l \epsilon_i / 2 < 0 \quad \text{for even } l \leq 2k .$$

We define

$$y_1 = e_l,$$

$$y_2 = \alpha_2 e_1 + \beta_2 e_2 + e_i \quad \text{for } \beta_2 \neq 0 ,$$

$$y_l = \alpha_2 e_1 + \beta_2 e_2 - e_i$$

and

$$y_i = \alpha_i e_1 + \beta_i e_2 + \gamma_i e_l + e_i \quad \text{for } i \neq 1, 2, l, \beta_i \neq 0 ,$$

where $\beta_i$ and $\gamma_i$ are chosen such that $y_i$ satisfies (8), while $\alpha_i$ are chosen such that $F(y_i) = 0$. This proves (vii).

To prove (vii)(a) and (vii)(b) assume now that the quadratic form in (8) is semidefinite and that the symmetric matrix corresponding to the quadratic form in (8) has rank $n - k - r$, where the $r$ zeroes among the $\epsilon_i (\mu_i - \lambda)$ occur for the indices $i = 2k + 1, \cdots, 2k + r$. Then the only unit vectors satisfying (8) are $e_1, e_3, \cdots, e_{2k-1}, e_{2k+1}, \cdots, e_{2k+r}$. And clearly $e_1, e_3, \cdots, e_{2k-1} \in Q_S \cap Q_T$ in either of the cases (vii)(a)
or (vii)(b).

In case of (vii)(a) exactly \( e_1, e_2, \ldots, e_{2k-1} \in Q_s \cap Q_T \), because the quadratic form in \( r \) variables

\[
\sum_{i=2k+1}^{2k+r} \varepsilon_i x_i^2
\]

appearing in \( F \) is definite and \( F(x) \neq 0 \) for all \( x \) with \( x_i \neq 0 \) for \( 2k < i \leq 2k + r \). So in this case we conclude that \( Q_s \cap Q_T \) contains a maximum of \( k \) lin. ind. vectors.

In case of (vii)(b)

\[
(9)
\sum_{i=2k+1}^{2k+r} \varepsilon_i x_i^2
\]

is an indefinite quadratic form and besides \( e_1, e_2, \ldots, e_{2k-1}, r \) more lin. indep. vectors \( y_1, \ldots, y_r \) can be found that satisfy \( F(x) = 0 \) and (8):

Choose \( y_i \) as follows. Since (9) is indefinite, there are indices \( 2k < l, j \leq 2k + r \) with \( \varepsilon_l = 1, \varepsilon_j = -1 \). Then define for \( 2k < i \leq 2k + r, \ i \neq l, j \):

\[
y_i = e_j + e_i \quad \text{if } F(e_i) = 1
\]

and

\[
y_i = e_j + e_i \quad \text{if } F(e_i) = -1
\]

while we set

\[
y_i = e_j + e_i
\]

and

\[
y_j = e_j - e_i.
\]

This proves (vii)(b).

(viii): Here we define

\[
F(x) = x' S x = 2x_i x_2 + \sum_{i=3}^{n} \varepsilon_i x_i^2
\]

and

\[
G(x) = x' T x = 2a x_i x_2 + b(x_i^2 - x_2^2) + \sum_{i=3}^{n} \varepsilon_i \mu_i x_i^2.
\]

So \( F(x) = G(x) = 0 \) is equivalent to

\[
(10) \quad F(x) = 0 \quad \text{and} \quad b(x_i^2 - x_2^2) + \sum_{i=3}^{n} \varepsilon_i (\mu_i - a)x_i^2 = 0.
\]
REAL VECTORS ANNIHILATED BY TWO QUADRATIC FORMS

Now unless (viii)(a) holds, not all \( \mu_i \) or \( \varepsilon_i \) are the same for \( i \geq 3 \). So for some pair of indices \( i, j \geq 3 \) we must have \( \mu_i \neq \mu_j \) or \( \varepsilon_i \neq \varepsilon_j \). After a suitable index permutation we may start the proof assuming that \( \mu_i \neq \mu_4 \) or \( \varepsilon_3 \neq \varepsilon_4 \) already.

We define \( y_1 = \alpha_1 e_1 + \beta_1 e_2 - e_3, y_2 = \alpha_2 e_1 + \beta_2 e_2 - e_4 \) and \( y_i = \alpha_i e_1 + \beta_i e_2 + e_i \) for \( i \geq 3 \), where the \( \alpha_i, \beta_i \) are chosen to satisfy

\[
(11) \quad b(\alpha_i^2 - \beta_i^2) + \varepsilon_i(\mu_i - \alpha) = 0 \quad \text{and} \quad 2\alpha_i\beta_i + \varepsilon_i = 0 \quad \text{for each } i .
\]

Then the vectors \( y_i \) for \( i \leq n \) are lin. ind. iff

\[
\det(y_1, \ldots, y_n) = \begin{vmatrix} \alpha_3 & \beta_3 & -1 & 0 \\ \alpha_4 & \beta_4 & 0 & -0 \\ \alpha_5 & \beta_5 & 1 & 0 \\ \alpha_4 & \beta_4 & 0 & 1 \end{vmatrix} = \begin{vmatrix} 2\alpha_3 & 2\beta_3 & 0 & 0 \\ 2\alpha_4 & 2\beta_4 & 0 & 0 \\ \alpha_5 & \beta_5 & 1 & 0 \\ \alpha_4 & \beta_4 & 0 & 1 \end{vmatrix} \neq 0.
\]

So the \( n \) vectors \( y_i \) in \( Q_s \cap Q_r \) are lin. dep. iff for the 2-vectors we have

\[
(12) \quad (\alpha_4, \beta_4) = d(\alpha_4, \beta_4)
\]

for some real coefficient \( d \). Now (12) holds only if \( d = \pm 1 \), for (12) implies \( \alpha_i\beta_j = d^2\alpha_i\beta_j \) and we know \( \alpha_4\beta_4 = -\varepsilon_4/2 \), since \( F(y_4) = 0 \) and \( \alpha_4\beta_4 = -\varepsilon_4/2 \), since \( F(y_4) = 0 \) and thus \( d = \pm 1 \).

If \( d = 1 \), then by (11) we have \( \varepsilon_3 = \varepsilon_4 \) and hence by assumption \( \mu_3 \neq \mu_4 \) which contradicts (11). If \( d = -1 \), then \( \varepsilon_3 = -\varepsilon_4 \) and \( \alpha_5\beta_3 = -\alpha_4\beta_4 \) by (11), contradicting (12).

Thus we found that the \( n \) vectors \( y_i \) in \( Q_s \cap Q_r \) are lin. ind. in case of (viii).

If (viii)(a) holds, \( \mu_i = \mu \) and \( \varepsilon_i = \varepsilon \) for all \( i \). We define for \( x = (x_1, \ldots, x_n) \)

\[
(13) \quad F(x) = x'Sx = 2x_1x_2 + \varepsilon \sum_{i=3}^{n} x_i^2
\]

and

\[
G(x) = x'Tx = 2a_2x_1x_2 + b(x_1^2 - x_2^2) + \varepsilon \mu \sum_{i=3}^{n} x_i^2 .
\]

And \( F(x) = G(x) = 0 \) is equivalent to

\[
(14) \quad F(x) = 0 \quad \text{and} \quad b(x_1^2 - x_2^2) + \varepsilon(\mu - \alpha) \sum_{i=3}^{n} x_i^2 = 0 .
\]

We define the following \( n - 1 \) lin. ind. vectors

\[
y_i = \alpha e_1 + \beta e_2 + e_i \quad \text{for } i \geq 3 ,
\]

\[
y_2 = \alpha e_1 + \beta e_2 - e_2 ,
\]

\[\text{This "or" does not mean "either... or".}\]
where \( \alpha, \beta \) are chosen such that \( F(y_i) = G(y_i) = 0 \) for all \( i \). Such numbers \( \alpha, \beta \) exist, since they can be chosen as the intersection of the following two hyperbolas

\[
2\alpha\beta + \varepsilon = 0; \quad \alpha^2 - \beta^2 = -\frac{\varepsilon}{b}(\mu - a).
\]

Now any \( w = (\beta_1, \cdots, \beta_n) \in Q_s \cap Q_T \) satisfies (14). We are going to show that if \( 0 \neq w \in Q_s \cap Q_T \) then the 2-vector \((\beta_1, \beta_2)\) can be written as \( \pm \|\hat{x}\| (\alpha, \beta) \) with \( \alpha, \beta \) as chosen above and \( \hat{x} = (0, 0, \beta_3, \cdots, \beta_n) \). Now if \( \|\hat{x}\| = 0 \), i.e., \( \beta_i = 0 \) for all \( i \geq 3 \), then by (14) \( \beta_1\beta_2 = 0 = \beta_1^2 - \beta_2^2 \) so that \( w = 0 \). If \( \beta_1 = 0 \), then by (13) we get \( w = 0 \).

So if \( w \neq 0 \) belongs to \( Q_s \cap Q_T \), then \( \|\hat{x}\| \neq 0 \) and we define \( d \) as \( d = \beta_1/\alpha \) with \( \alpha \) as introduced above. Using the equations \( F(w) = F(y_i) = 0 \) we get \( 2\alpha\beta = -\varepsilon = 2\beta_1\beta_2/\|\hat{x}\|^2 \) and hence \( \beta_2 = \|\hat{x}\|^2\beta/d \).

The second equation in (14), written out for \( y_i \) and \( w \), reads like

\[
b(\alpha^2 - \beta^2) + \varepsilon(\mu - a) = 0 = b(d^2\alpha^2 - \|\hat{x}\|^4\beta^2/d^2) + \varepsilon(\mu - a)\|\hat{x}\|^2,
\]
and hence

\[
\alpha^2 - \beta^2 = d^2\alpha^2/\|\hat{x}\|^4 - \|\hat{x}\|^4\beta^2/d^2.
\]

or

\[
d^4\alpha^2 + d^2\|\hat{x}\|^4(\beta^2 - \alpha^2) - \beta^2\|\hat{x}\|^4 = 0.
\]

This last equation in \( d \) has only two real roots, namely \( d = \pm \|\hat{x}\| \).

Hence \( \beta_2 = \pm \|\hat{x}\|\beta \), while \( \beta_1 = \pm \|\hat{x}\|\alpha \).

So the equation \( w = (\beta_1, \cdots, \beta_n) = d(\alpha e_1 + \beta e_2) + (0, 0, \beta_3, \cdots, \beta_n) = \sum_{i=2}^{n} \eta_i y_i \) can be solved for real coefficients \( \eta_i \), namely by \( \eta_i = \beta_i \) for \( i > 3 \),

\[
\eta_2 = \left(d - \sum_{i=3}^{n} \beta_i\right)/2
\]

and \( \eta_3 = \beta_3 + \eta_2 \), where

\[
d = \pm \left(\sum_{i=3}^{n} \beta_i^2\right)^{1/2}
\]

as we have seen above.

So every \( w \in Q_s \cap Q_T \) is lin. dep. of \( y_3, \cdots, y_n \) and in this case \( n - 1 \) is the maximal number of lin. ind. vectors in \( Q_s \cap Q_T \). This proves (viii)(a).

(ix): It only remains to show (ix): Let \( S \) and \( T \) be simultaneously diagonalizable.

Assume \( S \) is positive definite, then \( Q_s = \{0\} \) and hence for any symmetric \( T \) we have \( Q_s \cap Q_T = \{0\} \), hence the case \( k = 0 \) occurs.
If $S = \text{diag} (1, -1, \ldots, -1, 1, \ldots, 1)$ and $T = \text{diag} (\lambda, -\lambda, \ldots, -\lambda, 0, \ldots, 0)$ with $(l - 1)$ numbers $-1$ and $-\lambda$ appearing on the diagonals of $S$ and $T$, then $Q_S \cap Q_T$ contains a maximum of $l$ lin. indep. vectors for $\lambda \neq 0$, $2 \leq l \leq n$ as can be seen by inspection. Finally if $x \in Q_S \cap Q_T$, then $x$ can be written as $x = \alpha e_l + \beta e_k + y$ for two indices $l, k$, nonzero constants $\alpha, \beta$, and $y$ orthogonal to $e_l$ and $e_k$, because $x$ has to satisfy

$$F(x) = x' S x = \sum_{i=1}^{n} \varepsilon_i x_i^2 = 0$$

and

$$G(x) = x' T x = \sum_{i=1}^{n} \varepsilon_i \mu_i x_i^2 = 0, \quad \text{with } \varepsilon_i = \pm 1.$$ 

But then $\hat{x} = \alpha e_l - \beta e_k + y \in Q_S \cap Q_T$ as well and $x$ and $\hat{x}$ are lin. ind. So in case (ix) $Q_S \cap Q_T$ cannot contain just one vector and its multiples.

This proves Theorem 2.

Next we treat nonsingular pairs of real symmetric matrices that have dimensions 2 or 3.

**Theorem 3.** Let $S, T$ be a nonsingular pair of r.s. matrices of dimension $n$. Assume that $n = 2$ or 3. Let the Roman numerals (vi), \ldots, (viii) denote the various cases of Theorem 2.

If (vii) holds, then $Q_S \cap Q_T$ contains $n$ lin. ind. vectors.

In (vi)(a) or (viii)(a) (with $n = 3$) holds, then $Q_S \cap T_T$ contains a maximum of $n - 1$ lin. ind. vectors.

If (vii)(a) holds, then $Q_S \cap Q_T$ contains a maximum of $k$ lin. ind. vectors, where $k$ is defined as in Theorem 2.

If (viii)(a) holds with $n = 2$, then $Q_S \cap Q_T = \{0\}$.

**Proof.** In view of Lemma 2 we can again assume that $S$ and $T$ are already in canonical pair form.

(a) Let $n = 3$: If $J = S^{-1} T$ contains just one 3-dimensional block $J(\lambda, 3)$, then inertia $S = (2, 1, 0)$ or $(1, 2, 0)$ and we have condition (vi)(a). Then $F(x) = x' S x = \varepsilon (2x_1x_2 + x_3^2)$ and $G(x) = x' T x = \varepsilon (\lambda (2x_1x_2 + x_3^2) + 2x_2x_3)$ with $\varepsilon = \pm 1$. Hence the only vectors $x$ satisfying $F(x) = G(x) = 0$ are multiples of $e_1$ and of $e_3$. Hence there are at most 2 lin. ind. vectors in $Q_S \cap Q_T$.

If $S^{-1} T$ has a complex root, then we have case (viii)(a) and the proof of Theorem 2 (viii)(a) carries over.
If $S^{-1}T$ satisfies condition (vii), then we have for $\varepsilon_i = \pm 1$, $F(x) = x'Sx = \varepsilon_1(2x_1x_2) + \varepsilon_2x_3^2$ and $G(X) = x'Tx = \varepsilon_1(\lambda_2x_1x_2 + x_2^2) + \varepsilon_3\mu x_3^2$ and thus $F(x) = G(x) = 0$ is equivalent to

\[(15) \quad F(x) = 0 \quad \text{and} \quad \varepsilon_1x_2^2 + \varepsilon_3(\mu - \lambda)x_3^2 = 0.\]

If $\lambda = \mu$, then only multiples of $e_i$ are in $Q_s \cap Q_T$ and if $\lambda \neq \mu$, but $\varepsilon_i\varepsilon_3(\mu - \lambda) > 0$, then again only multiples of $e_i$ are in $Q_s \cap Q_T$. Now condition (vii)(a) encompasses exactly these two cases, hence if (vii)(a) holds, then $Q_s \cap Q_T$ is just a one dimensional space.

If (vii) holds, i.e., $\lambda \neq \mu$ and $\varepsilon_i\varepsilon_3(\mu - \lambda) < 0$, then we define

\[
y_1 = e_i \quad \text{and} \quad y_2 = \alpha e_i + \beta e_2 - e_3 \quad \text{where} \quad \alpha, \beta \neq 0
\]

are such that $y_s, y_2$ satisfy (15).

(b) If $n = 2$, we have in case of just one Jordan block $J(\lambda, 2)$ in $J = S^{-1}T$: $F(x) = x'Sx = \varepsilon(2x_1x_2)$ and $G(x) = x'Tx = \varepsilon(2\lambda_2x_1x_2 + x_2^2)$ for $\varepsilon = \pm 1$. So $F(x) = G(x) = 0$ holds iff $x = \alpha e_1$. Hence (vii)(a) is proved. In case of (viii)(a) for a Jordan block $J(a, b, 2)$ of type (B), we have $F(x) = 2x_1x_2$ and $G(x) = 2ax_1x_2 + b(x_1^2 - x_2^2)$. And hence $F(x) = G(x) = 0$ holds iff $x = 0$.

Let $S$ and $T$ be a nonsingular pair of r.s. matrices of dimension greater than 2. In Theorems 1, 2, and 3 we have seen how the real Jordan normal form of $S^{-1}T$ determines the maximal number of lin. ind. vectors in $Q_s \cap Q_T$. Since we have dealt with all possible real Jordan normal forms, we can reverse the argument and get the following:

**THEOREM 4.** Let $S$ and $T$ be a nonsingular pair of r.s. $n \times n$ matrices where $n > 2$.

Let $m = \max\{l| \text{there exist } l \text{ lin. ind. vectors in } Q_s \cap Q_T\}$. Let the Roman numerals (i), ..., (viii) denote the various conditions in Theorem 2.

If $m = 0$, then $S$ and $T$ can be simultaneously diagonalized by a real congruence transformation.

If $m = 1$, then (vii)(a) holds with $k = 1$.

If $2 \leq m \leq [n/2]$, then (vii)(a) holds with $k = m$ or (vii)(b) holds with $r = m - k$ for $S$ and $T$, or $S$ and $T$ can be diagonalized simultaneously.
If \( \lfloor n/2 \rfloor < m < n - 1 \), then (vii)(b) holds with \( r = m - k \) where \( k \leq \lfloor n/2 \rfloor \) for \( S \) and \( T \), or \( S \) and \( T \) can be diagonalized simultaneously.

If \( m = n - 1 \), then (vi)(a) or (viii)(a) or (vii)(b) holds with \( r = m - k \), where \( k \leq \lfloor n/2 \rfloor \) for \( S \) and \( T \), or \( S \) and \( T \) can be diagonalized simultaneously.

If \( m = n \), then (i), \( \cdots \) or (viii) holds for \( S \) and \( T \), or \( S \) and \( T \) can be diagonalized simultaneously by a real congruence transformation.

Here \([\ ]\) denotes the greatest integer function.

If \( m \), the maximal number of lin. ind. vectors simultaneously annihilated by two quadratic forms \( x'Sx, x'Tx \), lies properly between 1 and \( n - 1 \), and if we can rule out the cases (vii)(a) or (vii)(b), then we can conclude that \( S \) and \( T \) are simultaneously diagonalizable. For example, here are two such conditions that make (vii)(a) or (vii)(b) impossible to happen:

**Corollary 1.** Let \( S \) and \( T \) be a nonsingular part of r.s. \( n \times n \) matrices. Let \( m = \max \{ l | \text{there exist } l \text{ lin. ind. vectors in } Q_s \cap Q_t \} \).

Assume \( 1 < m < n - 1 \).

If (a) \( S^{-1}T \) is nonderogatory, or

(b) for every eigenvalue \( \lambda \) of \( S^{-1}T \) the number of associated lin. ind. eigenvectors is smaller than half the algebraic multiplicity of \( \lambda \), unless both are the same, then \( S \) and \( T \) can be diagonalized simultaneously by a real congruence transformation.

Nonderogators matrices are those that have only one Jordan block for each different eigenvalue.

As a further corollary to Theorem 4 \((m = 0)\) we get a result due to Greub and Milnor [1, p. 256]:

**Corollary 2.** Let \( S \) and \( T \) be a nonsingular pair of r.s. matrices. If \( Q_s \cap Q_t = \{0\} \), then \( S \) and \( T \) can be diagonalized simultaneously be a real congruence transformation.

**Acknowledgment.** This paper in essence constitutes Chapter 4 of my Ph. D. Thesis at the California Institute of Technology, 1971. I am indebted to my advisor Dr. Olga Taussky-Todd and to Dr. H. F. Bohnenblust for their guidance and advice. Dr. Olga Taussky-Todd suggested that in order to generalize the theorems known about simultaneous diagonalization of symmetric matrices one ought to study the set \( Q_s \cap Q_t \).

The Supporting Institutions listed above contribute to the cost of publication of this Journal, but they are not owners or publishers and have no responsibility for its content or policies.

Mathematical papers intended for publication in the Pacific Journal of Mathematics should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Items of the bibliography should not be cited there unless absolutely necessary, in which case they must be identified by author and Journal, rather than by item number. Manuscripts, in duplicate if possible, may be sent to any one of the four editors. Please classify according to the scheme of Math. Rev. Index to Vol. 39. All other communications to the editors should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints are provided free for each article; additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966. Regular subscription rate: $48.00 a year (6 Vols., 12 issues). Special rate: $24.00 a year to individual members of supporting institutions.

Subscriptions, orders for back numbers, and changes of address should be sent to Pacific Journal of Mathematics, 108 Highland Boulevard, Berkeley, California, 94708.
