MATRIX RINGS OVER POLYNOMIAL IDENTITY RINGS II

ELIZABETH BERMAN

If A is a ring satisfying a polynomial identity, what identity is satisfied by the matrix ring A_n ? Theorem: If A satisfies the standard identity of degree k, then A_n satisfies the standard identity of degree $2kn^2 - n^2 + 1$.

Definition: Suppose that $\{r_1, \dots, r_q\}$ is a sequence of elements of a ring. To parenthesize the sequence into j clumps is to insert j pairs of adjacent, nonoverlapping parentheses. The subsequence within one pair of parentheses constitutes a clump. It is odd or even, depending on the number of entries. The value of the clump is the product of the entries. If the value is zero, the clump vanishes.

In the following let Z represent the integers.

LEMMA 1. Let k, m, and n be positive integers. Let $\{u_1, \dots, u_m\}$ be a nonvanishing sequence of matrix units e_{ij} in Z_n .

(i) If m = kn, there exists i such that the sequnce can be parenthesized into k clumps, each of value e_{ii} .

(ii) If m = (kn - n + 1)n, there exist i and j such that the sequence can be parenthesized into k clumps, each of value e_{ii} , and each beginning with e_{ij} .

Proof of (i). Case 1. Suppose there exists *i* such that at least k + 1 of the entries in the sequence have *i* as initial subscript. Call the first k + 1 such entries y_1, y_2, \dots, y_{k+1} . Then parenthesize the sequence as follows: start with y_1 . Enclose it in parentheses, together with all entries to the right, if any, up to y_2 . Next parenthesize y_2 with all entries up to y_3 , etc. We form *k* clumps, each beginning with a y. Since each clump has to the right an entry with *i* as initial subscript, and the sequence is nonvanishing, each clump has value e_{ii} .

Case 2. Suppose that for all i, at most k of the entries have i as initial subscript. Since the sequence has kn entries, every i from l through n occurs exactly k times as an initial subscript.

Case 2a. The last entry is an idempotent e_{ii} . There are previous entries y_1, \dots, y_{k-1} , each with *i* as initial subscript. Start with y_1 and

enclose it in parentheses with all entries to the right, up to y_2 . Continue, forming k - 1 clumps, each of value e_{ii} . Then form a final clump consisting of the single e_{ii} at the end.

Case 2b. The last entry is e_{ij} , with $i \neq j$. Then there are k previous entries y_1, \dots, y_k with j as initial subscript. Parenthesize, forming k - 1 clumps, beginning with y_1, y_2, \dots, y_{k-1} , respectively. Then form a final clump, beginning with y_k and ending with the last e_{ij} . The result is k clumps, wach of value e_{ij} .

Proof of (ii). Let m = (kn - n + 1)n. Let $\{u_1, \dots, u_m\}$ be a nonvanishing sequence of matrix units. Let t = kn - n + 1. By (i) there exists *i* such that the sequence can be parenthesized into *t* clumps, each of value e_{ii} . Let y_1, \dots, y_t be the first entries in these clumps. Each y has *i* as initial subscript. The second subscript can be any integer from 1 through *n*. Now

$$t = kn - n + 1 = (k - 1)n + 1.$$

Thus for some j, at least k of the y's have j as second subscript. Suppose that $y_{f(1)}, \dots, y_{f(k)}$ are all e_{ij} . Make new clumps as follows: start with $y_{f(1)}$ and enclose it in parentheses together with all entries to the right, up to $y_{f(2)}$. Continue, forming k - 1 clumps. In the old parenthesizing $y_{f(k)}$ was the initial entry in a clump of value e_{ii} . Let this old clump be the k th clump in the new parenthesizing. The result is k clumps, each of value e_{ii} , and each beginning with e_{ij} .

Theorem 3.2 of [2] established that if A is an algebra satisfying a standard identity, so is A_n . The following theorem improves this result in three ways: (1) the degree of the identity satisfied by A_n is much lower. (2) The theorem holds for rings, not just algebras over fields. (3) The proof is simpler.

THEOREM 1. If A is a ring satisfying the standard identity of degree k, then A_n satisfies the standard identity of degree $2kn^2 - n^2 + 1$.

Proof. Let

$$t = 2kn^2 - n^2 + 1 = (2k - 1)n^2 + 1.$$

Choose t simple tensors in $A \otimes Z_n$ of form $a \otimes e_{ij}$, where $a \in A$, and e_{ij} is a matrix unit. Evaluate on these simple tensors the standard polynomial of degree t. Consider only nonvanishing terms.

Case 1. Suppose that for some i, at least k simple tensors have form

 $a_1 \otimes e_{ii}, \cdots, a_k \otimes e_{ii}$.

Let $y = e_{ii}$. Call the remaining elements

$$b_1 \otimes z_1, b_2 \otimes z_2, \cdots$$

Insert parentheses on the right side of each term: start with the first y and enclose it with all z's to the right, if any. Similarly parenthesize the next y with its z's, etc. The last y forms a singleton clump. Thus k clumps are created, each beginning with e_{ii} , and each of value e_{ii} . If there are any z's in the clump, call them the z sub-clump. It also has value e_{ii} .

Let V be the number of even clumps, and let D be the number of odd clumps. Then V + D = k. Each even clump yields two new odd clumps: the initial y and the z sub-clump. The result is 2V + D adjacent odd clumps, each of value e_{ii} . Note that $2V + D \ge V + D = k$.

In each term find the first set of k adjacent odd clumps of value e_{ii} . Create a corresponding set of clumps on the left side. Call two terms equivalent if the following conditions hold on their left sides:

1. The elements to the left of the clumps are the same elements in the same order.

2. The k clumps are the same, but in any order.

3. The elements to the right of the clumps are the same elements in the same order.

Consider a fixed equivalence class. The sum of the terms in the class is a simple tensor whose right side has the common value for the class. The left side is the product of the following:

1. The product of all elements left of the clumps.

2. The standard polynomial of degree k, evaluated on the values of the k clumps, in some order.

3. The product of all the elements right of the clumps. (Because all these clumps are odd, Corollary to Lemma 4 of [4] ensures correctness of signs of terms.) Since the second factor vanishes, the conclusion follows.

Case 2. Suppose that Case 1 does not hold. Since there are $(2k-1)n^2+1$ simple tensors, by Lemma 1 (ii) there exist *i* and *j* such that at least 2k simple tensors have form $a \otimes e_{ij}$. Evidently, $i \neq j$. Let $w_{ii} = e_{ii} + e_{ij}$. Then w_{ii} is idempotent, and

In each term replace e_{ij} by $w_{ii} - e_{ii}$. Let N be the original number of e_{ij} 's. Each old term, upon expansion, yields 2^N new terms. Every new term has on the right a monomial in w's and e's. If there are at least k of the e_{ii} 's in the term, it is suitable for Case 1. Otherwise there are at least k of the w_{ii} 's. In this case, define new elements as follows:

$$w_{jj} = -e_{ij} + e_{jj}$$
$$w_{ji} = -e_{ii} - e_{ij} + e_{ji} + e_{ji}$$

If $i \neq p \neq j$, let

$$w_{pi} = e_{pi} + e_{pj}$$

 $w_{jp} = -e_{ip} + e_{jp}$

For the remaining integers from 1 through n, let $w_{pq} = e_{pq}$.

The w's constitute another set of matrix units in Z_n . Each old matrix unit e_{pq} is a linear combination of the w's with integral coefficients. Replace all the e's by w's. The conclusion follows by the linearity of the standard polynomial and by Case 1.

DEFINITION. The unitary identity of degree k is

$$\sum_{\pi} x_{\pi(1)} \cdots x_{\pi(k)} = 0,$$

where the sum is over all permutations π of the integers 1 through k.

THEOREM 2. If A is a ring satisfying the unitary identity of degree k, then A_n satisfies the unitary identity of degree kn.

Proof. The proof uses Lemma 1 (i) and is similar to Theorem 1 of [4].

THEOREM 3. If A is an algebra over a field with at least k elements, and A satisfies $x^{k} = 0$, then A_{n} satisfies $x^{kn} = 0$.

Proof. The proof uses Lemma 1(i) and is similar to Theorem 1.2 of [3]. Note: That paper uses without definition the term "homogeneous component" of a polynomial. If $f(x_1, \dots, x_i)$ is a polynomial, the homogeneous component of degree n_1 in x_1 , degree n_2 in x_2 , etc., is the sum of all terms with degree n_1 in x_1 , etc.
