CERTAIN CLASSES OF REGULAR UNIVALENT FUNCTIONS

V. KARUNAKARAN
CERTAIN CLASSES OF REGULAR UNIVALENT FUNCTIONS

V. KARUNAKARAN

If \( f(z) \) and \( g(z) \) are starlike functions of orders \( \alpha \) and \( \gamma \) for \( \alpha, \gamma \in [0, 1) \), then it is shown that

\[
F(z) = \frac{2}{g(z)} \int_0^z f(t) dt
\]

is \( \beta \)-starlike for \( |z| < \delta \), where \( \delta \) is a function of \( \alpha, \beta, \gamma \). Conversely, a sharp estimate is obtained for the radius of \( \beta \)-starlikeness of the class of functions

\[
f(z) = 2^{-1}(g(z)F(z))'
\]

where \( g(z) \) and \( F(z) \) are starlike functions of orders \( \gamma \) and \( \alpha \) respectively, with \( \alpha + \gamma \leq 1 \).

Let \( S \) denote the family of functions \( f(z) \) which are regular and univalent in the unit disc \( E \) of the complex plane and which satisfy the conditions \( f(0) = 0 = f'(0) - 1 \). Let \( S^* \subset S \) denote the class of starlike functions, namely those members of \( S \) which map \( E \) onto a domain that is starlike with respect to the origin. Libera [2] showed that if \( f(z) \in S^* \), then

\[
F(z) = \frac{2}{z} \int_0^z f(t) dt
\]

also belongs to \( S^* \). In the converse direction, Livingston [4] has studied the mapping properties of the function

\[
f(z) = 2^{-1}(zF(z))'
\]

where \( F(z) \in S^* \). The object of this paper is to generalize these results of Libera and Livingston by choosing instead of \( S^* \) the class \( S^*(\alpha) \) of starlike functions of order \( \alpha \) and replacing the definition of \( F(z) \) in (1) by

\[
F(z) = \frac{2}{g(z)} \int_0^z f(t) dt
\]

where \( f(z) \) and \( g(z) \) are starlike functions of orders \( \alpha \) and \( \gamma \) respectively. Extensions of the results of Libera and Livingston in other directions were made by Padmanabhan [6], Nikolaéva and Repniná, [5], Bernardi [1].

**Theorem 1.** If \( f(z) \in S^*(\alpha) \) and \( g(z) \in S^*(\gamma) \), then the function \( F(z) \) defined by
\[ F(z) = \frac{2}{g(z)} \int_{0}^{z} f(t) dt \]

is \( \beta \)-starlike for \( |z| < \sigma = \sigma(\alpha, \beta, \gamma) \) where \( \sigma \) is given by

\[
\sigma[1 + 2\alpha - 2\gamma - \beta] = [(2 - \alpha - \gamma)^2 + (1 - \beta)(1 + 2\alpha - 2\gamma - \beta)]^{1/2} - (2 - \alpha - \gamma)
\]

when \( 1 + 2\alpha - 2\gamma - \beta \neq 0 \), \( 2\sigma(2 - \alpha - \gamma) = 1 - \beta \) when \( \beta = 1 + 2\alpha - 2\gamma \).

**Proof.** Let \( P(\alpha) \) denote the class of all regular functions \( p(z) \) in \( E \) which satisfy the conditions \( p(0) = 1, \Re[p(z)] > \alpha \) \( (0 < \alpha < 1) \). Examining the proof of Lemma 1 in [2] we easily find that if \( N \) and \( D \) are regular in \( E, \ N(0) = D(0) = 0, \ D \) maps \( E \) onto a many-sheeted region which is starlike with respect to origin and \( N'/D' \in P(\alpha) \), then \( N/D \in P(\alpha) \). Further we note that

\[
\sigma(z) = \int_{0}^{z} f(t) dt,
\]

where \( f(z) \in S^*(\alpha) \), is 2-valently starlike with respect to origin by [2, Lemma 2]. Now \( F(z) = 2\sigma(z)/g(z) \) where \( \sigma(z) = \int_{0}^{z} f(t) dt \). So,

\[
zF''(z)/F(z) = (z\sigma'(z)/\sigma(z)) - (zg'(z)/g(z)) = (z\sigma'(z) - \sigma(z))/\sigma(z) + 1 - (zg'(z)/g(z)),
\]

\( \sigma(z) \) being 2-valently starlike. If we choose \( N(z) = z\sigma'(z) - \sigma(z), \ D(z) = \sigma(z) \), then \( N'/D' = z\sigma'(z)/\sigma(z) = zf'(z)/f(z) \) is a member of \( P(\alpha) \). From the above observations we conclude that \( (z\sigma'(z) - \sigma(z))/\sigma(z) \) is also a member of \( P(\alpha) \). Now, \( g(z) \in S^*(\gamma) \) and so

\[
\Re \left[ \frac{zF''(z)}{F(z)} \right] \geq 1 + \frac{1 + (2\alpha - 1)r}{1 + r} - \frac{1 - (2\gamma - 1)r}{1 - r},
\]

since \( p(z) = zf'(z)/f(z) \in P(\alpha) \) implies \( \Re[p(z)] \geq (1 + (2\alpha - 1)r)/(1 + r) \) on \( |z| = r \), by a known result. Thus \( \Re \left[ zF''(z)/F(z) \right] \geq \beta \) on \( |z| = r \) and hence \( F(z) \) will be \( \beta \)-starlike for \( |z| < r \), if

\[
1 + \frac{1 + (2\alpha - 1)r}{1 + r} - \frac{1 - (2\gamma - 1)r}{1 - r} \geq \beta.
\]

This condition gives \( r < \sigma \) where \( \sigma \) is as given in Theorem 1. Theorem 1, together with the fact that every convex function is a starlike function of order 1/2, implies the following corollary.

**Corollary.** If \( f(z) \in S^*(\alpha) \) and \( g(z) \) is a convex univalent func-
tion in $E$, then the function

$$F(z) = \frac{2}{g(z)} \int_{0}^{z} f(t) dt$$

is $\beta$-starlike for $|z| < \sigma(\alpha, \beta, 2^{-1})$.

The limiting case $\gamma \to 1$ while $\alpha = \beta = 0$ gives the result of Libera [2].

Before proving our main theorem on a partial converse of Theorem 1, we prove two elementary lemmas which are important for our considerations.

LEMMA 1. Suppose $p(z) = [1 + Dw(z)][1 + Bw(z)]^{-1}$ where $w(z)$ is regular in $E$, $w(0) = 0$, $|w(z)| < 1$ for $z \in E$ and $-1 \leq D < B \leq 1$; then for any $C \geq B$, we have on $|z| = r < 1$,

$$\Re \left[ C p(z) + \frac{D}{p(z)} \right] - \frac{r^2 |B p(z) - D|^2 - |1 - p(z)|^2}{(1 - r^2) |p(z)|} \leq \begin{cases} P_1(r) & \text{for } R_0 \leq R_1, \\ P_2(r) & \text{for } R_0 \geq R_1, \end{cases}$$

where

$$P_1(r) = C \frac{1 + Dr}{1 + Br} + D \frac{1 + Br}{1 + Dr},$$

$$P_2(r) = \frac{2}{(1 - r^2)} \left[ \frac{(1 + D)^{1/2}}{(1 + C - (D(1 + C) + B^2 + C)r^2 + D(B^2 + C)r^4)^{1/2} - (1 - BDr^2)} \right],$$

$$R_0^2 = \frac{(1 + D)(1 - Dr^2)}{(1 + C) - r^2(C + B^2)}$$

and

$$R_1 = \frac{1 + Dr}{1 + Br}.$$

**Proof.** A hint for the following proof is in [7]. $p(z)$ is subordinate to the linear fractional transformation $(1 + Az)/(1 + Bz)$ and from this it follows by elementary arguments that

$$|p(z) - a| \leq d,$$

where
If \( p(z) = a + u + iv \) with \( a \) as defined above and \( R^2 = |p(z)|^2 = (a + u)^2 + v^2 \), then by a simple computation

\[
\text{Re}\left[CP(z) + \frac{D}{p(z)}\right] - \left\{ \frac{r^2 |Bp(z) - D|^2 - |1 - p(z)|^2}{(1 - r^2)|p(z)|} \right\} = C(a + u) + \frac{D(a + u)}{R^2} + \frac{(1 - B^2r^2)(u^2 + v^2 - d^2)}{(1 - r^2)R} \equiv S(u, v), \text{ say}.
\]

Then

\[
\frac{\partial S(u, v)}{\partial v} = vR^{-1}T(R),
\]

where

\[
T(R) = -2D(a + u) + 2B^2(1 - r^2)^{-1}(1 - B^2r^2) + R(1 - r^2)^{-1}(1 - B^2r^2)(d^2 - u^2 - v^2).
\]

Evidently,

\[
T(R) \geq 2(a + u)\left[\frac{(1 - B^2r^2)}{1 - r^2}(a - d)^2 - D\right] \geq 0,
\]

since \( R \geq a + u \geq a - d \), as is easily verified. Thus \( S(u, v) \), as a function of \( v \), attains its minimum when \( v = 0 \) and the minimum value is given by

\[
\min_v S(u, v) = S(u, 0) \equiv L(R) = CR + \frac{D}{R} + \left(\frac{1 - B^2r^2}{1 - r^2}\right)\frac{1}{R}[R^2 + a^2 - 2ar - d^2],
\]

since \( v = 0 \) implies \( a + u = R \). The absolute minimum of \( L(R) \) is attained at \( R = R_0 = (m/l)^{1/2} \), where

\[
m = D + (1 - r^2)^{-1}(a^2 - d^2)(1 - B^2r^2),
\]

\[
l = C + (1 - r^2)^{-1}(1 - B^2r^2).
\]

However, since \( a - d \leq R \leq a + d \), \( R \) takes the value \( R_0 \) only when \( a - d \leq R_0 \leq a + d \). It can be verified that \( R_0 \leq a + d \), while \( R_0 \) may not always be greater than \( a - d \). Further if \( R_0 < a - d \leq R \), then \( R_0^2 = m/l < R^2 \) and so \( L(R) \) is a monotonic increasing function of \( R \). Thus \( L(R) \) attains its minimum \( L(a - d) \) at \( R = a - d \). A computation shows that \( L(a - d) = P_1(r) \) and \( L(R_0) = P_2(r) \) where
$P_1(r)$ and $P_2(r)$ are as defined in Lemma 1. This completes the proof of Lemma 1.

**Lemma 2.** If $w(z)$ is regular in $E$ and satisfies $|w(z)| \leq |z|$ for $z \in E$ and $p(z) = [1 + Dw(z)][1 + Bw(z)]^{-1}$, then

$$\text{Re}\left\{ \frac{zw'(z)}{[1 + Bw(z)][1 + Dw(z)]} \right\} \leq -\frac{1}{(B - D)^2}\left\{ \text{Re}\left[ \frac{D}{p(z)} + Bp(z) \right] - \left[ \frac{r^2 |Bp(z) - D|^2 - |1 - p(z)|^2}{(1 - r^2)|p(z)|} \right] - (B + D) \right\}.$$

**Proof.** $\Phi(z) = z^{-1}w(z)$ satisfies $|\Phi(z)| \leq 1$ in $E$ and so by a well-known result, we have,

$$|\Phi'(z)| \leq (1 - |\Phi(z)|^2)(1 - |z|^2)^{-1}.$$

Thus using $\Phi(z) = z^{-1}w(z)$, we get

$$|zw'(z) - w(z)| \leq (r^2 - |w(z)|^2)(1 - r^2)^{-1}.$$

So we have on $|z| = r$,

$$\text{Re}\left\{ \frac{zw'(z)}{[1 + Bw(z)][1 + Dw(z)]} \right\} \leq \text{Re}\left\{ \frac{w(z)}{[1 + Dw(z)][1 + Bw(z)]} \right\} + \left\{ \frac{r^2 - |w(z)|^2}{(1 - r^2)|1 + Dw(z)|[1 + Bw(z)]} \right\}.$$

A simple computation using $w(z) = (1 - p(z))(Bp(z) - D)^{-1}$, gives the inequality stated in Lemma 2.

**Theorem 2.** Let $g(z) \in S^*(\gamma)$ and $F(z) \in S^*(\alpha)$ and define $f(z)$ by

$$F(z)g(z) = 2\int_0^z f(t)dt,$$

or, equivalently, by

$$f(z) = 2^{-1}(g(z)F(z))',$$

then for $|z| = r$,

$$\text{Re}\left[ \frac{zf'(z)}{f(z)} \right] \geq \begin{cases} P_1(r) & \text{for } R_0 \leq R_1, \\ P_2(r) & \text{for } R_0 \geq R_1, \end{cases}$$

where
\[ P_1(r) = \frac{1}{1-A}\left\{(3-2A)\left[\frac{1+Ar}{1+r}\right] + A\left[\frac{1+r}{1+Ar}\right] - 2\right\}, \]
\[ P_2(r) = \frac{2}{1-A}\left\{\left[\frac{(1+A)(4-2A)(1-Ar^2)}{1-r^2}\right]^{1/2} - \left[\frac{7-Ar^2}{1-r^2}\right] - 1\right\}, \]
\[ R_0 = (1+A)(1-Ar^2)/(4-2A)(1-r^2), \]
\[ R_1 = (1+Ar)/(1+r), \]

and
\[ A = \alpha + \gamma - 1. \]

These bounds are sharp.

Proof. \(2f(z) = g(z)F'(z) + F(z)g'(z).\)

So
\[ \frac{2zf(z)}{g(z)F(z)} = \frac{zf'(z)}{F(z)} + \frac{zf(z)}{g(z)}. \quad (3) \]

\(F(z) \in S^*(\alpha)\) and \(g(z) \in S^*(\gamma)\) imply that \(zf'(z)/F(z) \in P(\alpha)\) and \(zf(z)/g(z) \in P(\gamma)\). Thus \(zf(z)/g(z)F(z) \in P((\alpha + \gamma)/2)\) and so, by a well-known representation formula, we have
\[ \frac{zf(z)}{g(z)F(z)} = \frac{1+Aw(z)}{1+w(z)}, \]

where \(A = \alpha + \gamma - 1\) and \(w(z)\) is regular in \(E\) and satisfies \(|w(z)| \leq |z|\) for \(z \in E\). Let \(p(z) = [1+Aw(z)][1+w(z)]^{-1}\), then we have
\[ zf(z) = g(z)F(z)p(z). \quad (4) \]

Thus,
\[ \frac{zf'(z)}{f(z)} = \frac{zf'(z)}{g(z)} + \frac{zf''(z)}{F(z)} + \frac{zp'(z)}{p(z)} - 1 \]
\[ = 2p(z) + \frac{zp'(z)}{p(z)} - 1, \]

using (3) and (4). Now,
\[ \frac{zp'(z)}{p(z)} = \frac{-(1-A)zw'(z)}{[1+Aw(z)][1+w(z)]}. \]

An application of Lemma 2 and then Lemma 1 with \(C = 3-2A\), \(B = 1\) and \(D = A\) gives immediately the inequality stated in Theorem 2.

We now show that the bounds are sharp. Let us choose \(g(z) \in S^*(\gamma)\) and \(F(z) \in S^*(\alpha)\) defined by the formulas,
CERTAIN CLASSES OF REGULAR UNIVALENT FUNCTIONS

The corresponding \(f_1(z) = 2^\gamma(g_1(z)F_1(z))'\) satisfies

\[
p_1(z) = \frac{zf_1(z)}{g_1(z)F_1(z)} = \frac{1 + Aw_1(z)}{1 + w_1(z)}, \quad A = \alpha + \gamma - 1.
\]

From the proof of Lemma 1 it is evident that the bounds \(P_1(r)\) and \(P_2(r)\) will be attained only when \(R = a - d\) and \(R = R_0\) respectively, where \(R = |p(z)| = \text{Re } p(z)\). Since \(a - d = (1 + Ar)/(1 + r)\), the function \(w_1(z) \equiv z\) will give \(g_1(z), F_1(z)\) such that \(|p_1(z)| = \text{Re } p_1(z) = a - d\) at \(z = r\) and so the bound \(P_1(r)\) will be attained by the corresponding function \(zf_1'(z)/f_1(z)\), at \(z = r\), for all \(r\) satisfying \(R_0 \leq R_1\). When \(R_0 \geq R_1 = a - d\), we choose \(w_2(z) = z(z - q)/(1 - qz)\) where \(q\) is determined by the condition that \(p_2(z) = (1 + Aw_2(z))/(1 + w_2(z))\) satisfies \(|p_2(z)| = R_0 = \text{Re } p_2(z)\) at \(z = r\). Now we have

\[
a - d = R_1 \leq R_0 \leq a + d,
\]

so

\[
\frac{1 + Ar}{1 + r} \leq \frac{1 + AT}{1 + T} \leq \frac{1 - Ar}{1 - r},
\]

where \(T = w_2(r)\) and this in turn implies one of the three following equivalent conditions,

\[
\frac{r^2(r - q)^2}{(1 - qr)^2} = T^2 \leq r^2,
\]

\[
q^2 \leq 1,
\]

\[
|q| \leq 1.
\]

So \(w_3(z)\) is indeed subordinate to \(z\) in \(E\) and hence \(p_3(z)\) belongs to \(P((\alpha + \gamma)/2)\). Clearly, \(g_3(z) \in S^*(\gamma)\) and \(F_3(z) \in S^*(\alpha)\) defined by the formulas

\[
\frac{zg_3'(z)}{g_3(z)} = \frac{1 + (2\gamma - 1)w_3(z)}{1 + w_3(z)}, \quad \frac{zF_3'(z)}{F_3(z)} = \frac{1 + (2\alpha - 1)w_3(z)}{1 + w_3(z)},
\]

give rise to \(f_3(z)\) which satisfies \(|p_3(r)| = \text{Re } p_3(r) = R_0\), where

\[
p_3(z) = \frac{zf_3(z)}{g_3(z)F_3(z)} = \frac{1 + Aw_3(z)}{1 + w_3(z)},
\]

and so \(zf_3'(z)/f_3(z)\) attains the bound \(P_3(r)\) at \(z = r\).

**Theorem 3.** If the family \(Q\) is defined by
then the radius of \( \beta \)-starlikeness of the family \( Q \) is the least positive root of the equation \( P_1(r) - \beta = 0 \), where \( P_1(r) \) is as defined in Theorem 2.

Proof. By Theorem 2, the minimum of \( \text{Re}(zf'(z)/f(z)) \) for \( f \) belonging to \( Q \) is \( P_1(r) \) for all \( |z| = r \) satisfying \( R_0 \leq R_1 \). Thus, for \( R_0 \leq R_1 \), the requirement that \( f(z) \) be \( \beta \)-starlike for \( |z| < r \) gives the condition on \( r \) as \( P_1(r) - \beta \geq 0 \). This condition will be true for all values of \( r < \sigma \) where \( \sigma \) is the least positive root of the equation \( P_1(r) - \beta = 0 \), since \( P_1(0) - \beta > 0 \) for all \( \beta \in [0, 1) \). It remains to verify that \( \sigma \) also satisfies the condition

\[
(R_0)_{r=\sigma} \leq (R_1)_{r=\sigma}.
\]

For this we note that \( R_0^2 = (1 + A)(1 - Ar^3)/(1 - r^3)(4 - 2A) \) and so

\[
2 \frac{dR_0}{dr} = \frac{(1 - A^2)2r}{(1 - r^3)(4 - 2A)} \geq 0.
\]

Thus \( R_0 \) is an increasing function of \( r \). Moreover \( R_1 = (1 + Ar)/(1 + r) \) implies

\[
\frac{dR_1}{dr} = \frac{(1 - A)(1 - 2Ar^2)}{(1 + r)^2} < 0
\]

and so \( R_1 \) is a decreasing function of \( r \). Thus the equation \( R_0 - R_1 = 0 \) has at the most one root in \( (0, 1] \). The inequality \( R_0 - R_1 \leq 0 \) holds if and only if

\[
T(r) = A(1 - 2A)r^3 + A(2A - 7)r^2 + (4A - 5)r + 3 \geq 0.
\]

Now \( T(0) = 3 > 0 \) and \( T(1) = -2(1 + A) \leq 0 \) and so \( R_0 - R_1 = 0 \) has at least one root in \( (0, 1] \). Let the unique root of the equation \( T(r) = 0 \) be \( r_A \). Thus the condition \( R_0 \leq R_1 \) holds for some \( r \) if and only if \( r \leq r_A \). Thus \( R_0 \leq R_1 \) holds at \( r = \sigma \) if and only if \( \sigma \leq r_A \). Now \( P_1(r) - \beta \) satisfies \( P_1(0) - \beta > 0 \). We show \( P_1(r_A) \leq 0 \). This will imply that \( P_1(r_A) - \beta \leq 0 \) and, in particular, that \( \sigma \), the least positive root of the equation \( P_1(r) - \beta = 0 \), will satisfy \( \sigma \leq r_A \). Now a calculation shows that

\[
P_1(r) = \frac{r^2(2A^2 - A) + r(4A - 2) + 1}{1 + (1 + A)r + Ar^2}.
\]

Therefore \( P_1(r) \leq 0 \) if \( r \) exceeds the least positive root of the equation

\[
x^3(2A^2 - A) + x(4A - 2) + 1 = 0.
\]
CERTAIN CLASSES OF REGULAR UNIVALENT FUNCTIONS

i.e., \( P(r) \leq 0 \) if \( r \geq (1 - t)/s \) where

\[
s = -A \geq 0, \quad t = \left( \frac{1 - A}{1 - 2A} \right)^{1/2}.
\]

So \( P(r, s) \leq 0 \) if \( r, s \geq (1 - t)/s \). But \( r, s \geq (1 - t)/s \) if and only if \( T((1 - t)/s) \geq 0 \), since \( T(r) = 0 \) has a unique root in \((0, 1]\) and \( T(0) > 0 \). Changing \( A \) to \(-s\), we get the fact that \( T(r) \geq 0 \) if and only if,

\[-r^2(1 + 2s)s + (2s + 7)s r^2 - (4s + 5)r + 3 \geq 0.
\]

Substituting \( r = (1 - t)/s \) and using elementary calculations, the condition reduces to

\[-4s(1 - s^3) - 4s(1 - s) - (2s + 1) \leq 0.
\]

Since \( A = \alpha + \gamma - 1 \leq 0 \) and \( s = -A \), the last inequality is trivially true. Further, the bounds obtained in Theorem 2 are sharp and so the radius \( \sigma \) obtained above is also sharp for the family \( Q \) under consideration and this completes the proof of Theorem 3.

**REMARKS.** It should be noted that we have not used the full force of Lemma 1, in the proof of Theorem 3. Other conditions on \( F(z) \) and \( g(z) \) such as

\[
\left| \frac{z F'(z)}{F(z)} - 1 \right| z F'(z) + 1 \left| z F'(z) - 1 \right| < \alpha \quad 0 < \alpha \leq 1,
\]

or

\[
\left| \frac{z F'(z)}{F(z)} - \alpha \right| < \alpha \quad \alpha > \frac{1}{2},
\]

or

\[
\left| \frac{z F'(z)}{F(z)} - 1 \right| < \alpha \quad 0 < \alpha \leq 1,
\]

where \( F(z) = (g(z)F(z))^{1/2}; F(0) = 1 \), could be considered instead of \( F(z) \) being in \( S^*((\alpha + \gamma)/2) \) as in Theorem 3. Problems with these conditions can be solved similarly by choice of suitable values for \( A, B, C \) in Lemma 1. Also the case \( \alpha + \gamma > 1 \) left out in the theorem can be treated using the above estimates. Details relating to this case which involve difficult calculations will be published on another occasion. Further, from Theorem 3, it follows that if \( \alpha + \gamma = 1 \), the radius of \( \beta \)-starlikeness of the family \( Q \) is given by \( \sigma = (1 - \beta)/(2 + \beta) \) and this is a slight generalization of [3, Corollary 2 to Theorem 1].

The author would like to thank Professor K. S. Padmanabhan for...
helpful discussions. He also thanks a referee who suggested a better presentation of the material.
