ULTRAFILTERS AND THE BASIS PROPERTY

RICHARD ALEXANDER SANERIB, JR.
ULTRAFILTERS AND THE BASIS PROPERTY

RICHARD A. SANERIB, JR.

Three notions of a basis for an ultrafilter in a Boolean algebra are investigated in this paper, namely having an independent set of generators, a weakly independent set of generators and a weakly independent set of generators over a proper subfilter. In general these three notions are distinct, but for a Boolean algebra with an ordered base the latter two are equivalent. This paper shows that a large class of Boolean algebras do not possess ultrafilters with a basis, in particular no infinite homomorphic image of a $\sigma$-complete Boolean algebra has a nonprincipal ultrafilter with a basis. For Boolean algebras with an ordered base necessary and sufficient conditions on the order type of the base are given for the Boolean algebra to have the basis property.

Introduction. The notion of an independent family of sets was first introduced in [1] by Fichtenholz–Kantorovitch. Their results were generalized in [3] by Hausdorff where it was shown that, if $|I| = m$, there exists an independent family of subsets of $I$ of power $2^m$. It is well known that the free Boolean algebra on $m$ generators is generated by an independent family of elements of power $m$ and that every ultrafilter in this algebra has an independent set of generators. A weaker notion, that of an irredudant set of generators, or a weakly independent set of generators, has been considered by both A. Tarski [11] and I. Reznikoff [7] in the setting of mathematical logic, and it is the algebraic version of this notion which we call a basis for an ultrafilter. Boolean algebras in which every ultrafilter has a basis are said to have the basis property. The idea of an independent set modulo a filter has been used by K. Kunen in [4] and this leads to the property considered here, that of a basis over a filter.

The first section consists of the definitions and basic lemmas concerning the above mentioned three notions and a theorem showing that a large class of Boolean algebras do not have the basis property. In §2 Boolean algebras with an ordered base are considered and for this class of Boolean algebras necessary and sufficient conditions on the order type of the base are given for the Boolean algebra to have the basis property. For these Boolean algebras, the latter two notions of a basis are shown to be equivalent and further, any such Boolean algebra with the basis property must have cardinality less than or equal to $2^\kappa$. Finally a summary of the relationships between these three concepts of basis is given.
Preliminaries. If $\mathcal{A}$ is a Boolean algebra we assume $\mathcal{A} = (A, \lor, \land, - , 0, 1)$ and if $\mathcal{F}$ is a filter in $\mathcal{A}$, and $a \in A$, we write $a/\mathcal{F} = \bar{a}$. The basic results concerning Boolean algebras may be found in [2] or [10]. We recall that a filter in a Boolean algebra is generated by $\{b_v\}_{v < \alpha} \subset \mathcal{F}$ if for each $a \in \mathcal{F}$ there exists $\nu_1, \cdots, \nu_k < \alpha$ with $b_{\nu_1} \land \cdots \land b_{\nu_k} \leq a$. A family of elements $\{a_v\}_{v < \alpha} \subset A$ is independent if, for all $\nu_1, \cdots, \nu_n < \alpha$ which are distinct, $b_{\nu_1} \land \cdots \land b_{\nu_n} \neq 0$ where for each $i$, $b_{\nu_i} = a_{\nu_i}$ or $-a_{\nu_i}$.

1. DEFINITION 1.1. A filter $\mathcal{F}$ in a Boolean algebra $\mathcal{A}$ is said to have a basis $\{a_v\}_{v < \alpha}$ if

(i) $\{a_v\}_{v < \alpha}$ generates $\mathcal{F}$, and

(ii) if $\nu_0, \cdots, \nu_{n+1} < \alpha$ are distinct, then $a_{\nu_0} \land \cdots \land a_{\nu_n} \not\subseteq a_{\nu_{n+1}}$.

A Boolean algebra is said to have the basis property if each ultrafilter has a basis. The definition of basis is weaker than that of independent set of generators. For example, in the Boolean algebra of finite and cofinite subsets of $\omega$, there is only one nonprincipal ultrafilter and it has a basis but does not have an independent set of generators:

If $\{A_n\}_{n \in \omega} \subset \mathcal{F}$ is an independent set of generators then each $A_n$ is cofinite. Let $B_0 = \{n_1, \cdots, n_k\} = \sim A_0$ and, for $i = 1, \cdots, k$, let

$$B_i = \begin{cases} A_i & \text{if } n_i \in A_i \\ \sim A_i & \text{otherwise} \end{cases}$$

Then $B_0 \subset B_1 \cup \cdots \cup B_k$. We may assume without loss of generality that $B_0 \subset (\sim A_1 \cup \cdots \cup \sim A_j) \cup (A_{j+1} \cup \cdots \cup A_k)$. Thus, since $B_0 = \sim A_0$, we have $(A_1 \cap \cdots \cap A_j) \cap \sim A_0 \subset (A_{j+1} \cup \cdots \cup A_k)$ and hence $A_1 \cap \cdots \cap A_j \subset A_0 \cup A_{j+1} \cup \cdots \cup A_k$ which contradicts the independence of the $A_i$'s. On the other hand, the complements of singletons form a basis for $\mathcal{F}$.

Condition (ii) is an irredundancy condition and is the algebraic translation of the logical notion of an independent set of formulas, apparently first introduced by Tarski [11]. This algebraic version will be referred to as weak independence. In this connection, it is interesting to note that Reznikoff in [7] showed that every filter in a free Boolean algebra has a basis. The following notion of a basis for one filter over another filter is a modification of the definition of being independent modulo a filter (See [4]):

DEFINITION 1.2. Let $\mathcal{G}$ and $\mathcal{F}$ be filters in the Boolean algebra $\mathcal{A}$ with $\mathcal{F} \nsubseteq \mathcal{G}$. $\{a_v\}_{v < \alpha} \subset \mathcal{F}$ is a basis for $\mathcal{F}$ over $\mathcal{G}$ if
ULTRAFILTERS AND THE BASIS PROPERTY

(i) \( G \cup \{a_v\}_{v<\alpha} \) generates \( \mathcal{F} \) and

(ii) if \( \nu_0, \ldots, \nu_{n+1} < \alpha \) are distinct, then \(-a_{\nu_0} \vee \cdots \vee -a_{\nu_{n+1}} \notin G\).

In particular, condition (ii) allows one to extend \( G \) to a proper filter containing \( a_{\nu_0} \land \cdots \land a_{\nu_{n+1}} \).

If \( \mathcal{F} \) is a filter in a Boolean algebra \( \mathfrak{A} \), and \( \mathcal{I} = \{-x: x \in \mathcal{F}\} \) then \( \mathcal{I} \) is an ideal and, by \( \mathfrak{A}/\mathcal{F} \) we mean the quotient algebra \( \mathfrak{A}/\mathcal{I} \).

**Lemma 1.3.** Let \( \mathfrak{A} \) be a Boolean algebra, \( \mathcal{F} \) an ultrafilter in \( \mathfrak{A} \), \( G \) a filter in \( \mathfrak{A} \), \( \mathfrak{A} = \mathfrak{A}/G \) and \( \mathcal{F} = \{\tilde{a}: a \in \mathcal{F}\} \). Then \( \mathcal{F} \) has a basis over \( \mathcal{F} \cap G \) if and only if \( \mathcal{F} \) has a basis in \( \mathfrak{A} \).

**Proof.** It is straightforward to verify that \( \{a_v\}_{v<\alpha} \) is a basis for \( \mathcal{F} \) over \( \mathcal{F} \cap G \) if and only if \( \{\tilde{a}_v\}_{v<\alpha} \) is a basis for \( \mathcal{F} \) in \( \mathfrak{A} \).

**Lemma 1.4.** Let \( \mathfrak{A} \) be an infinite Boolean algebra and \( \{x_n\}_{n \in \omega} \) an infinite set of distinct ultrafilters in \( \mathfrak{A} \). Then there exists an infinite subsequence \( \{x_{n_k}\}_{k \in \omega} \subset \{x_n\}_{n \in \omega} \) and \( \{a_k\}_{k \in \omega} \subset A \) of pairwise disjoint elements with \( a_k \in x_{n_k} \).

**Proof.** Let \( b_0 \in x_0 \) with \(-b_0, x_1 \) and let \( B_0 = \{x_0: b_0 \in x_0\} \). If \( \mid B_0 \mid = \aleph_0 \), set \( B_0 = B_1 \), \( a_0 = -b_0 \), \( c_0 = b_0 \) and \( n_0 = 1 \). If \( \mid B_0 \mid \neq \aleph_0 \), set \( B_0 = B_1 \), \( a_0 = b_0 \), \( c_0 = -b_0 \) and \( n_0 = 0 \). Suppose \( \{a_k\}_{k \leq m}, \{c_k\}_{k \leq m}, \{x_{n_k}\}_{k \leq m} \) and \( \{B_k\}_{k \leq m} \) have been defined with \( B_k \) infinite for \( k \leq m \) and \( i < j \leq m \) implies \( B_i \subseteq B_j \) and for all \( k \leq m \) we have

(i) \( a_k \in x_{n_k} \) and \( c_k \in x \) for all \( x \in B_k \), \( a_k \land a_i = 0 \) if \( k \neq i \) and \( a_k \land c_i = 0 \) for all \( k \leq i \).

Let \( x_0 \) and \( x_1 \) be distinct elements of \( B_0 \) of the form \( x_n \) where \( n > n_m \), and let \( b_m \in x_0 \) with \(-b_m, x_1 \). Then \( c_m \land b_m \subset x_0 \) and \( c_m \land -b_m \subset x_1 \). Let \( B_{m+1} = \{y \in B_m: c_m \land b_m \subset y\} \), \( B_{m+1} = \{y \subset B_m: c_m \land -b_m \subset y\} \).

If \( \mid B_{m+1} \mid = \aleph_0 \), let \( B_{m+1} = B_{m+1} \), \( a_{m+1} = c_m \land -b_m \), \( c_{m+1} = c_m \land b_m \) and \( x_{n_{m+1}} = x_0 \). If \( \mid B_{m+1} \mid \neq \aleph_0 \), let \( B_{m+1} = B_{m+1} \), \( a_{m+1} = c_m \land -b_m \), \( c_{m+1} = c_m \land b_m \) and \( x_{n_{m+1}} = x_0 \). Clearly \( \{x_{n_k}\}_{k \in \omega} \) and \( \{a_k\}_{k \in \omega} \) so defined have the desired properties.

**Theorem 1.5.** Let \( \mathfrak{A} \) be a \( \sigma \)-complete Boolean algebra, \( G \) a filter in \( \mathfrak{A} \) and \( \mathcal{F} \) an ultrafilter in \( \mathfrak{A} \) with \( \mathcal{F} \supseteq G \). Then \( \mathcal{F} \) has a basis over \( G \) if and only if there exists a \( b \in A \) such that \( \mathcal{F} \) is generated by \( G \cup \{b\} \).

**Proof.** Obviously if \( \mathcal{F} \) is generated by \( G \cup \{b\} \) then \( \mathcal{F} \) has a basis over \( G \). Now suppose \( \mathcal{F} \) has a basis \( \{a_v\}_{v<\alpha} \) over \( G \) and that \( \alpha \) is infinite (if \( \alpha \) is finite, then clearly \( G \cup \{b\} \) generates \( \mathcal{F} \) where \( b = \)
$a_0 \wedge a_1 \wedge \cdots \wedge a_{n-1}$). Let $\mathcal{F}_v$ be an ultrafilter in $\mathcal{A}$ such that $\mathcal{F}_v \supset \mathcal{G} \cup \{a_\mu \}_{\mu < \alpha, \mu \notin v} \cup \{-a_v\}$. This is possible by the definition of a basis over $\mathcal{G}$.

(1) If $a \in \mathcal{F}$ then $\{v < \alpha : a \notin \mathcal{F}_v\}$ is finite. Since $a \in \mathcal{F}$ there exists $b \in \mathcal{G}$ and $\nu_0, \cdots, \nu_n < \alpha$ such that $b \wedge a_{\nu_0} \wedge \cdots \wedge a_{\nu_n} \equiv a$ and $a \in \mathcal{F}_v$ for all $v \neq \nu_0, \cdots, \nu_n$.

By Lemma 1.4 there exists a subsequence $\{\mathcal{F}_v\}$ of $\{\mathcal{F}_v\}_{v < \alpha}$ and $b_k \in \mathcal{F}_v$ such that $b_k \wedge b_j = 0$ for $k \neq j$. Since $\mathcal{G}$ is $\sigma$-complete there exist $b = \bigvee_{k \in \omega} b_{2k}$ and $c = \bigvee_{k \in \omega} b_{2k+1}$. Since $b \in \mathcal{F}_v$ for all $k$ we have $-b \notin \mathcal{F}$ by (1) and therefore $b \in \mathcal{F}$. Similarly $c \in \mathcal{F}$. But $b \wedge c = 0$ which contradicts $0 \notin \mathcal{F}$. Thus if $\mathcal{F}$ has a basis in $\mathcal{A}$, the basis is finite.

**Corollary 1.6.** Let $\mathcal{A}$ be a $\sigma$-complete Boolean algebra and $\mathcal{B}$ a homomorphic image of $\mathcal{A}$. Then no nonprincipal ultrafilter in $\mathcal{B}$ has a basis.

**Proof.** Immediate by the previous theorem and Lemma 1.3.

One easily sees that if $\mathcal{A}$ has the basis property, this does not imply that, given an ultrafilter $\mathcal{F}$ extending a filter $\mathcal{G}$, $\mathcal{F}$ has a basis over $\mathcal{G}$. For example let $\mathcal{A}_m$ be the free Boolean algebra on $m$ generators and let $\mathcal{B}$ be an atomless $\sigma$-complete Boolean algebra with $|\mathcal{B}| < m$. Then there exists a filter $\mathcal{G}$ in $\mathcal{A}_m$ such that $\mathcal{A}_m/\mathcal{G} \equiv \mathcal{B}$, but if $\mathcal{F}$ is an ultrafilter extending $\mathcal{G}$, then $\mathcal{F}$ has no basis over $\mathcal{G}$ by Lemma 1.3 and Corollary 1.6. It is interesting to note that for Boolean algebras with an ordered base, if an ultrafilter has a basis then it has a basis over every filter which it extends (see 2.5 and the remark preceding it). If an ultrafilter has a basis over every proper filter which it extends then it does have a basis since it has a basis over $\{1\}$. In fact if $\mathcal{G} \subset \mathcal{F}$, such that $\mathcal{F}$ has a basis over $\mathcal{G}$ and there exists $a \in \mathcal{F}$ with $a \leq b$ for all $b \in \mathcal{G}$, then $\mathcal{F}$ has a basis in $\mathcal{A}$.

**Corollary 1.7.** Let $\mathcal{A}$ be Boolean algebra and $\mathcal{F}$ an ultrafilter in $\mathcal{A}$. If $\mathcal{F}$ has a basis over every proper subfilter, then $\mathcal{F}$ has a basis in $\mathcal{A}$.

In addition to free Boolean algebras, it is well known that every countable Boolean algebra has the property that all nonprincipal ultrafilters have a basis.

The following lemma, probably first proved by Tarski [9] establishes this result:

**Lemma 1.8.** Let $\mathcal{F}$ be an ultrafilter in a Boolean algebra $\mathcal{A}$ such that $\mathcal{F}$ has a countable set $\{a_n\}_{n \in \omega}$ of generators. Then $\mathcal{F}$ has a basis.
Proof. Assume without loss of generality that \(a_0 \neq 1\) and for \(n < m\), \(a_n > a_m\). Let \(b_n = a_n \lor (\lor_{k<n} - a_k)\).

1. \(a_n \leq b_n\) for all \(n \in \omega\),
2. \(a_n \leq b_m\) for all \(n < m\),
3. \(b_n \lor b_m = 1\) for all \(n \neq m\).

Now

4. \(\{b_n\}_{n \in \omega}\) is weakly independent if \(\{b_{k_1} \land \cdots \land b_{k_n}\} \leq b_{k_{n+1}}\), then
   \(- (b_{k_1} \land \cdots \land b_{k_n}) \land b_{k_{n+1}} = 1\).

But, since \(b_{k_i} \lor b_{k_{n+1}} = 1\) for \(1 \leq i \leq k\) by (3), we have
\((b_{k_1} \land \cdots \land b_{k_n}) \lor b_{k_{n+1}} = 1\). Since \(b_{k_{n+1}} \neq 1\), this is a contradiction.

5. \(\{b_n\}_{n \in \omega}\) generates \(\mathcal{F}\).

A simple inductive proof shows \(a_n = \land_{i \leq n} b_i\).

Corollary 1.9. Let \(\mathcal{A}\) be a \(\sigma\)-complete Boolean algebra and \(\mathcal{B}\) a homomorphic image of \(\mathcal{A}\). Then no nonprincipal ultrafilter in \(\mathcal{B}\) has a countable set of generators.

Proof. By 1.6 and 1.8.

From 1.9, the well-known result that no infinite homomorphically image of a \(\sigma\)-complete Boolean algebra is countable is immediate.

The question of whether every projective Boolean algebra has the basis property is open. Since little is known about projective Boolean algebras a positive answer to this question would be most interesting. A characterization of those Boolean algebras with the basis property, or one for those ultrafilters with a basis — perhaps in terms of chains in the filter — are additional areas of investigation. These latter two problems are answered completely in the case of Boolean algebras with an ordered base in the next section.

2. In this section we restrict the discussion to Boolean algebras with an ordered base. These Boolean algebras were first introduced by Mostowski and Tarski in [6] and have been studied more recently by Mayer and Pierce [5] and Rotman [8] where additional references may be found. Rotman shows that in a Boolean algebra with an ordered base there are at most countably many independent elements. The question for weakly independent elements appears to be open.

Definition 2.1. A Boolean algebra \(\mathcal{A}\) has an ordered base \(X\) if \(X\) is linearly ordered by \(<\) (the order in \(\mathcal{A}\)), \(X\) generates \(\mathcal{A}\), \(0 \in X\) and \(1 \notin X\).

If \((A, \leq)\) is a linearly ordered set, then the cofinality of \(A\) (cf(A)) is
inf{|B|: for all $a \in A$ there exists $b \in B \subseteq A$ with $a \leq b$. The coinitiality of $A$ ($ci(A)$) is the inf{|B|: for all $a \in A$ there exists a $b \in B \subseteq A$ with $b \leq a$}. An initial segment of $A$ is a set $B \subseteq A$ such that if $b \in B$ and $a < b$ then $a \in B$. A tail of $A$ is the complement of an initial segment.

**Lemma 2.2.** Let $\mathcal{U}$ be a Boolean algebra with ordered base $X$, $Y$ an initial segment of $X$ and $\mathcal{F}$ an ultrafilter in $\mathcal{U}$ containing $\{-y: y \in Y\} \cup (X \sim Y)$. If $x \in \mathcal{F}$, then there exists $y \in Y$ and $z \in X \sim Y$ such that $x \geq -y \land z$.

**Proof.** Since $X$ is a set of generators for the Boolean algebra and $\mathcal{F}$ is an ultrafilter, the conclusion is obvious.

**Theorem 2.3.** If $\mathcal{U}$ is a Boolean algebra with ordered base $X$, and there exists an initial segment $Y \subseteq X$ with $cf(Y) > \aleph_0$ or there exists a tail $Z \subseteq X$ with $ci(Z) > \aleph_0$, then $\mathcal{U}$ does not have the basis property of ultrafilter.

**Proof.** We may assume there exists an initial segment $Y \subseteq X$ with $cf(Y) > \aleph_0$, for otherwise $\emptyset \cup \{-x: x \in X \sim \emptyset\}$ is an ordered basis with an initial segment $Z$ having cofinality greater than $\aleph_0$. Let $Y = \{a_i\}_{i \in I}$ and let $\mathcal{F}$ be an ultrafilter such that $\mathcal{F} \supset \{-a_i\}_{i \in I}$ and $\mathcal{F} \supset X \sim Y$. Suppose $\mathcal{F}$ has a basis $\{c_\alpha\}_{\alpha < \lambda}$.

1. $|\lambda| > \aleph_0$ — we first note that no finite meet $d$ of basis elements is less than or equal to all $-a_n$ for otherwise by Lemma 2.2 there exists $-a_i$ and $x \in X \sim Y$ with $-a_i \land x \leq d \leq -a_i$ for all $i \in I$. Hence $-a_i \land x \leq -a_i \land x$ for all $i \in I$. Choosing $a_i > a_i$ we have $a_i < x$ since $Y$ is an initial segment of $X$. Thus $a_i \land -a_i \land x = a_i \land -a_i = 0$ so $a_i \leq a_n$, a contradiction.

By the above argument, $|\lambda| \geq \aleph_0$, so assume $|\lambda| = \aleph_0$. Let $d_n = c_0 \land \cdots \land c_n$. Again by above argument, for each $n \in \omega$ there exists $-a_n$ such that $d_n \leq -a_n$. Since $cf(Y) > \aleph_0$, we arrive at an obvious contradiction — hence (1) is established.

2. $\mathcal{F}$ has no basis.

**Case 1.** $ci(X \sim Y) > \aleph_0$.

Let $\{b_j\}_{j \in J} = X \sim Y$. By Lemma 2.2 there exists $i_0 \in I$ and $j_0 \in J$ with $c_0 \geq -a_n \land b_n \geq d_0$ where $d_0$ is a finite meet of the basis elements $\{c_\alpha\}_{\alpha < \lambda}$. By Lemma 2.2, choose $i_j \in I$ and $j_i \in J$ such that $-a_i \land b_n < d_0$. Proceeding in this manner we construct $c_0 \geq -a_n \land b_n \geq d_0 \geq \cdots$
- \( a_n \land b_n \supseteq d_n \supseteq \cdots \) where \( - a_n \land b_n > - a_{n+1} \land b_{n+1} \) and \( d_n \) is a finite meet of basis elements. Since \( \text{cf}(Y) > \aleph_0 \), there exists \( a \in Y \) with \( - a \leq - a_n \) for all \( n \in \omega \) and \( b \in X \sim Y \) with \( b \leq b_n \) for all \( n \in \omega \). Hence \( - a \cdot b \leq d_n \) for all \( n \in \omega \). Now there exist \( \nu_1, \cdots, \nu_k \) with \( c_\nu \land \cdots \land c_{\nu_k} = - a \land b \leq d_n \) for all \( n \in \omega \). Since the \( d_n \)'s are strictly decreasing, there exists \( c_{\nu_k} \) occurring in some \( d_m \) with \( c_{\nu_k} \neq c_{\nu_1}, \cdots, c_{\nu_k} \). Hence \( c_{\nu_k} \land \cdots \land c_{\nu_k} \leq d_m < c_{\nu_k} \) contradicting the weak independence of the \( c_\nu \)'s.

**Case 2.** \( \text{ci}(X \sim Y) \leq \aleph_0 \).

We observe that for each \( a \in Y \) and \( b \in X \sim Y \), \( |\{c\ell: - a \land b \leq c\ell\}| < \aleph_0 \) — for otherwise there exist \( c_{\nu_1}, \cdots, c_{\nu_k} \) with \( c_{\nu_1} \land \cdots \land c_{\nu_k} = - a \land b \) with \( - a \land b \) less than infinitely many \( c_{\nu_k} \)'s which contradicts the weak independence of the \( c_{\nu_k} \)'s. Let \( \{b_n\}_{n \in \omega} \) be coinitial with \( X \sim Y \). Let \( B_n = \{c\ell: - a \land b \leq c\ell \text{ for some } i \in I\} \). Since \( \bigcup_{n \in \omega} B_n = \{c\ell\}_{c > a} \) and \( \lambda \) is uncountable there is an \( n_0 \) with \( B_{n_0} \) infinite. This implies there is a countable \( I_0 \subset I \) such that \( |\{c\ell: - a \land b \leq c\ell \text{ for some } i \in I_0\}| \leq \aleph_0 \). Since \( \text{cf}(Y) > \aleph_0 \) there exists \( - a \in Y \) with \( - a \leq - a_i \) for all \( i \in I_0 \). Hence \( - a \land b_n \) is less than or equal to infinitely many basis elements — a contradiction.

**Theorem 2.4.** Let \( \mathcal{A} \) be a Boolean algebra with ordered base \( X \). If \( \text{cf}(Y) \leq \aleph_0 \) for every initial segment \( Y \) of \( X \) and \( c_\ell(Z) \leq \aleph_0 \) for every tail \( Z \) of \( X \), then \( \mathcal{A} \) has the basis property for ultrafilters.

**Proof.** Let \( \mathcal{F} \) be an ultrafilter in \( \mathcal{A} \). Let \( Y = \{y \in X: y \notin \mathcal{F}\} \).

Then \( Y \) is an initial segment of \( X \) and, by Lemma 2.2, \( \mathcal{F} \) is generated by \( \{ - y: y \in Y \} \cup (X \sim Y) \). By hypothesis there is a countable sequence \( \{x_n\} \) which is coinitial in \( X \sim Y \) and a countable sequence \( \{y_n\} \) which is cofinal in \( Y \). Clearly \( \mathcal{F} \) is generated by \( \{ - y_n\} \cup \{x_n\} \). Therefore, by Lemma 1.8 \( \mathcal{F} \) has a basis.

Theorems 2.3 and 2.4 completely characterize the order types of ordered bases which give rise to Boolean algebras with the basis property for ultrafilters.

Boolean algebras with an ordered base which have the basis property for ultrafilters have in fact a stronger property — namely, every ultrafilter has a basis over every filter which it contains (see remark following 1.6). This is established by Lemma 1.3 and the following:

**Corollary 2.5.** Let \( \mathcal{A} \) be a Boolean algebra with ordered base \( X \) and suppose \( \mathcal{A} \) has the basis property for ultrafilters. If \( \mathcal{B} \) is a homomorphic image of \( \mathcal{A} \) then \( \mathcal{B} \) has the basis property for ultrafilters.
Proof. Let \( h : \mathcal{A} \to \mathcal{B} \) be a homomorphism and let \( X' = h(X) \sim \{1\} \).
Then one easily checks that \( X' \) is an ordered base for \( \mathcal{B} \). By 2.4 it suffices to check that if \( Y' \) is any initial segment of \( X' \) and \( Z' \) is any tail of \( X' \), then \( \text{cf}(Y') \leq \aleph_0 \) and \( \text{ci}(Z') \leq \aleph_0 \). Since \( Y = \{ y \in X : h(y) \in Y' \} \) has cofinality \( \leq \aleph_0 \) by 2.3, it is easy to verify that \( \text{cf}(Y') \leq \aleph_0 \). Similarly, one sees that \( \text{ci}(Z') \leq \aleph_0 \).

By the proof of 2.3 and 2.4 it is clear that if \( \mathcal{A} \) is a Boolean algebra with an ordered basis \( X \) and \( \mathcal{F} \) is an ultrafilter in \( \mathcal{A} \) then \( \mathcal{F} \) has a basis iff \( \text{cf}(Y) \leq \aleph_0 \) and \( \text{ci}(Z) \leq \aleph_0 \) where \( Y = \{ x \in \mathcal{F} : x \notin X \} \) and \( Z = \{ x \in \mathcal{F} : x \in X \} \). Similarly, as in 2.5, if \( \mathcal{F} \) has a basis and \( \mathcal{G} \subset \mathcal{F} \), then \( \mathcal{G} \) has a basis in \( \mathcal{A}/\mathcal{G} \). Combined with 1.8 this gives us

**Corollary 2.6.** If \( \mathcal{A} \) is a Boolean algebra with an ordered base and \( \mathcal{F} \) is an ultrafilter in \( \mathcal{A} \) then the following are equivalent:
(i) \( \mathcal{F} \) has a basis
(ii) \( \mathcal{F} \) has a basis over every filter \( \mathcal{G} \subset \mathcal{F} \).

**Theorem 2.7.** Let \( \mathcal{A} \) be a Boolean algebra with an ordered base \( X \). If \( \mathcal{A} \) has the basis property for ultrafilters, then \( |\mathcal{A}| \leq 2^{\aleph_0} \).

Proof. Let \( X^* \) be the completion by cuts of \( X \). Then \( X^* \) is a compact, first countable Hausdorff space under the order topology and hence has cardinality \( \leq 2^{\aleph_0} \) (see [9]). As a consequence \( |\mathcal{A}| \leq 2^{\aleph_0} \).

We summarize results concerning our three notions of basis in the following table where we use the notation:
(I) \( \mathcal{F} \) has an independent set of generators
(II) \( \mathcal{F} \) has a basis
(III) \( \mathcal{F} \) has a basis over every proper subfilter.
