STANDARD REGULAR SEMIGROUPS

RONSON JOSEPH WARNE
STANDARD REGULAR SEMIGROUPS

R. J. WARNE

We give a structure theorem for a class of regular semigroups. Let \( S \) be a regular semigroup, let \( T \) denote the union of the maximal subgroups of \( S \), and let \( E(T) \) denote the set of idempotents of \( T \). Assume \( T \) is a semigroup (equivalently, \( T \) is a semilattice \( Y \) of completely simple semigroups \( (T_y : y \in Y) \)). If \( Y \) has a greatest element and \( e, f, g \in E(T) \), \( e \geq f \), and \( e \geq g \) imply \( fg = gf \), we term \( S \) a standard regular semigroup. The structure of \( S \) is given modulo right groups and an inverse semigroup \( V \) in which every subgroup is a single element by means of an explicit multiplication. We specialize the structure theorem to orthodox, \( \omega Y \)-unipotent, and inverse semigroups, and to a class of semigroups with \( Y \) an \( \omega Y \)-semilattice.

Finally, we show that \( S \) is a regular extension of \( T \) by \( V \) in the sense of Yamada [19].

Let us first state the structure theorem. Let \( Y \) be a semilattice with greatest element. Let \( V \) be an inverse semigroup with semilattice of idempotents \( Y \) such that each subgroup of \( V \) consists of a single element. Let \((I, \circ)\) be a standard regular semilattice \( Y \) of left zero semigroups \((I_y : y \in Y)\). Let \((J, *)\) be a standard regular semilattice \( Y \) of right groups \((J_y : y \in Y)\). Suppose \( I_y \cap J_y = \{e_y\} \), a single idempotent element, and \( e_y^*e_z = e_y \circ e_z = e_{yz} \) for all \( y, z \in Y \). Let \( H_y \) denote the maximal subgroup of \( J_y \) containing \( e_y \). Let \( \varphi : I \to P(J) \), the semigroup of right translations of \((J, *)\), be a mapping of \( I \) into \( P(J) \), the semigroup of right translations of \((J, *)\), and let \( \beta \) be a mapping of \( V \) into \( \text{End}(J, \ast) \), the semigroup of endomorphism of \((J, \ast)\), and let \( g \) be a mapping of \( V \) into \( H = \bigcup (H_y : y \in Y) \), a semilattice \( Y \) of groups \((H_y : y \in Y)\) (with respect to the multiplication \( \ast \) in \( J \)) such that 1(a) \( jB_i \in H_y \) for \( i \in I_y \) and \( j \in J \), \( (b) J_y B_0 \subseteq H_{b^{-1}r_b} \), \( (c) g(c, d) \in H_{(ed)^{-1}ed} \). 2(a) \( hB_y = h\beta_y = h^*e_y \) for \( h \in J \) and \( y \in Y \). \( (b) \) if \( j \in H_x \) and \( i \in I_z \), \( jB_i = j \) \( (c) \) \( g(y, z) = e_{yz} \) for \( y, z \in Y \). 3(a)

\[
\beta_c \beta_d = \beta_{cd} c_{g(c,d)} \quad \text{ for } x, z \in H
\]

(b) \( g(a, bc)^*g(b, c) = g(ab, c)^*g(a, b)\beta_z \). Let \((Y, I, J, V, B, \beta, g)\) denote \((i, a, j) : a \in V, i \in I_{aa^{-1}}, j \in J_{a^{-1}a}\) under the multiplication \((i, a, j)(w, b, v) = (i \circ e_{(ab)(ab)^{-1}}, ab, g(a, b)^*jB_{w}\beta_b^*v) \).

We show (Theorem 3.14) that \((Y, I, J, V, B, \beta, g)\) is a standard regular semigroup, and, conversely, every standard regular semigroup is isomorphic to some \((Y, I, J, V, B, \beta, g)\).
If $X$ is a semigroup, $E(X)$ will denote the set of idempotents of $X$. Let $\mathcal{R}, \mathcal{L}, \mathcal{H},$ and $\mathcal{D}$ denote Green’s relations (notation of [1]).

Using [1, Theorem 2.3], $\mathcal{H}$ is the identity congruence on $V$. Hence, using a result of Munn [5, Theorem 2.3; see also 6], $V$ is isomorphic to a subsemigroup $U$ of the semigroup $X$ of isomorphisms between principal ideals of $E(V)$ with $E(U) = E(X)$.

In special cases, explicit multiplications for $V$ have been given (see for example [8] and [4]). Probably, the most familiar example of $V$ is the bicyclic semigroup.

The multiplication for $J$ is described by means of “connecting homomorphisms” between the $J_y$ (i.e. if $a \in J_y$, $b \in J_z$, $a \ast b = a\zeta_{y,z} \ast b\zeta_{z,z}$ where $\zeta_{y,z}(y \geq z)$ is a homomorphism of $J_y$ into $J_z$). The multiplication for $I$ is similarly characterized (see Remarks 1.7, 1.8, and 3.15).

A regular semigroup $X$ is termed locally inverse if $e, f, g \in E(X)$, $e \geq f$, and $e \geq g$ imply $fg = gf$. (Let $X$ be a regular semigroup and let $e \in E(X)$. Hence, if $a \in eXe$, there exists $y \in X$ such that $a = a\gamma a = (ae)y(\gamma a) = a(e\gamma a)$. Thus, the semigroup $eXe$ is also regular. Hence, using [1, Theorem 1.17], a regular semigroup $X$ is locally inverse if and only if $eXe$ is an inverse semigroup for all $e \in E(X)$). Thus, a standard regular semigroup is a locally inverse semigroup such that $T$ is a semigroup and $Y$ has a greatest element.

Following Hall [3], a regular semigroup $X$ is termed orthodox if $E(X)$ is a semigroup. In general, a standard regular semigroup is not orthodox.

Yamada [18, Theorem 2] described the structure of locally inverse orthodox semigroups in terms of inverse semigroups (locally inverse orthodox = generalized inverse in the sense of Yamada [18, Theorem 1]).

A Cliffordian semigroup is a semigroup which is a union of its subgroups. A semigroup $S$ is Cliffordian if and only if $S$ is a semilattice $Y$ of completely simple semigroups ($S_y : y \in Y$) (Clifford, [1, Theorem 4.6]).

In §1, we show that the multiplication of a locally inverse Cliffordian semigroup $S$ is described by means of connecting homomorphisms between the $S_y$ (Theorem 1.6) and give some consequences of this theorem. The results of this section are applied repeatedly in the sequel.

In §§2 and 3, we prove the converse and direct parts, respectively, of our structure theorem (Theorem 3.14).

Let $N$ denote the nonnegative integers and let $Y$ be a semilattice with greatest element. If $W = N \times Y$ with $(k, \alpha)\lambda(s, \lambda) = (k, \alpha, (s, \lambda))$, or $(k, \alpha\lambda\lambda)$ according to whether $k > s$, $s > k$, or $s = k$, we term $W$ an $\omega Y$-semilattice. A regular semigroup $S$ is termed $\omega Y$-$\mathcal{L}$-unipotent if $E(S)$ is an $\omega Y$-semilattice of right zero semigroups ($E(n, \delta) : (n, \delta) \in$
If \( E_{(n, \delta)} \) is a single element for each \((n, \delta) \in N \times Y\), we term \( S \) an \( \omega Y \)-inverse semigroup.

Munn [5, Theorem 3.3] described the structure of simple \( \omega Y \)-inverse semigroups. In [10, Theorem 4], Warne described the structure of simple \( \omega Y \)-\( \mathcal{L} \)-unipotent semigroups such that \( e \in E_{(n, \delta)}, f \in E_{(m, \lambda)}, \) and \((n, \delta) < (m, \lambda)\) implies \( e < f\). When specialized to inverse semigroups, this result yields a theorem [10, Corollary 5] equivalent to Munn’s theorem (see also [15, Lemma 2.1]). In [11, theorem and corollary], we show “simple” may be omitted. In [15, Theorem 6.1], we give a structure theorem for \( \omega Y \)-\( \mathcal{L} \)-unipotent semigroups.

Let \( S \) be a standard regular semigroup such that \( T \) is an \( \omega Y \)-semilattice of completely simple semigroups \( (T_{(n, \delta)}; (n, \delta) \in N \times Y)\). If \( f_{(n, \delta)} \mathcal{D} f_{(m, \lambda)} (f_{(n, \delta)} \in E(T_{(n, \delta)}); f_{(m, \lambda)} \in E(T_{(m, \lambda)})) \) if and only if \( \delta = \lambda \), we term \( S \) a standard regular semigroup of type \( \omega Y \).

In §4, we specialize Theorem 3.14 to obtain the structure of standard regular semigroups of type \( \omega Y \) (Theorem 4.2). In Theorem 4.2, the factor terms “\( g(c, d) \)” are omitted and \( V \) is an \( \omega Y \)-inverse semigroup with each subgroup a single element. Hence, an explicit multiplication for \( V \) is given by [15, Theorem 2.3]. Further specialization yields the structure of simple and bisimple standard regular semigroups of type \( \omega \) (\( T \) is an \( \omega \)-chain of completely simple semigroups—no condition of the \( \mathcal{D} \)-classes).

In §5, we describe the structure of standard orthodox, standard \( \mathcal{L} \)-unipotent, and standard inverse semigroups (Theorems 5.1, 5.3, and 5.5 respectively). A standard regular semigroup is termed standard orthodox (\( \mathcal{L} \)-unipotent)(inverse) if \( T \) is a semilattice of rectangular groups (right groups)(groups). The structure theorems are obtained by specializing Theorem 3.14. In each of the theorems the term “\( B \)”, is omitted. In Theorem 5.3 and 5.5, \( I_y = \{e_y\} \) for each \( y \in Y \). In Theorem 5.5, \( J_y = H_y \) for each \( y \in Y \).

Warne [9, page 206, paragraph 3] and Munn [5, page 66, paragraph 3] have exhibited inverse semigroups with identity on which \( \mathcal{H} \), Green’s relation, is not a congruence. Using Lemma 2.13, these semigroups are not standard.

Let \( S \) be a standard regular semigroup. If \( a \in S \), let \( \mathcal{I}(a) \) denote the collection of inverses of \( a \). Let \( t = \{(a, b) \in S^2; a a', b b' \in E(T_a) \text{ and } a' a, b' b \in E(T_b) \text{ for some } a', b' \in \mathcal{I}(a), b' \in \mathcal{I}(b), \text{ and } y, z \in Y\} \).

In §5, we show \( t \) is a congruence on \( S, S / t \cong V, \ker t = T, \) and \( S \) is a regular extension of \( T \) by \( S / t \) in the sense of Yamada [19].

We use the definitions of Clifford and Preston [1] unless otherwise specified. In particular, \( \mathcal{R}, \mathcal{L}, \mathcal{H}, \) and \( \mathcal{D} \) will denote Green’s relations on a semigroup \( S \), i.e., \( (a, b) \in \mathcal{R} \) if \( a \cup a S = b \cup b S \); \( (a, b) \in \mathcal{L} \) if \( a \cup S a = b \cup S b \); \( \mathcal{H} = \mathcal{R} \cap \mathcal{L} \); \( \mathcal{D} = \mathcal{R} \circ \mathcal{L} \) if there
exists \( x \in S \) such that \((a, x) \in R \) and \((x, b) \in S \)). \( R \) will denote the \( R \)-class containing \( a \in S \). A semigroup consisting of a single \( R \)-class is termed a bisimple semigroup. A semigroup \( S \) which is a union of a collection of pairwise disjoint subsemigroups \((S_y : y \in Y)\) where \( Y \) is a semilattice and \( S_y \subseteq S_z \) for all \( y, z \in Y \) is termed a semilattice \( Y \) of the semigroups \((S_y : y \in Y)\). If \( Y = N \) with \( n \wedge m = \max (n, m) \), \( S \) is termed an \( \omega \)-chain of the semigroups \((S_n : n \in N)\). A semigroup \( S \) is termed regular if \( a \in aSa \) for all \( a \in S \). If \( S \) is a regular semigroup, for each \( a \in S \), there exists \( \alpha \in S \) such that \( \alpha \alpha = a \) and \( \alpha \alpha^\prime = \alpha \) (for example, if \( a = \alpha \alpha \), let \( y = \alpha \alpha \) [1, Lemma 1.14]). The element \( y \) is termed an inverse of \( a \). A regular semigroup \( S \) is termed an inverse semigroup if each \( a \in S \) has precisely one inverse. A rectangular band is the algebraic direct product of a left zero semigroup \( U \) (\( x, y \in U \) implies \( xy = x \)) and a right zero semigroup. A rectangular group is the algebraic direct product of a group and a rectangular band. A right group is a semigroup \( X \) such that \( a, b \in X \) implies there exists a unique \( x \in X \) such that \( ax = b \). If \( S \) is a semigroup we may define a partial order \( \prec \) on \( E(S) \) by the rule: \( e \prec f \) means \( ef = fe = e \). A band is a semigroup \( S \) such that \( x^2 = x \) for each \( x \in S \). If \( S \) is a commutative band, \((S, \prec)\) is a semilattice with \( a \wedge b = a \wedge b \) and, conversely, every semilattice is a commutative band with \( ab = a \wedge b \) [1, Theorem 1.12]. A semigroup \( S \) is termed simple if \( S \) is its only ideal. If, furthermore, \( e, f \in E(S) \) and \( e \prec f \) imply \( e = f \), \( S \) is termed completely simple. The structure of such \( S \) is known modulo groups by theorem of Rees [1, Theorem 3.5].

1. Locally inverse Cliffordian semigroups. In this section, we give a characterization of locally inverse Cliffordian semigroups (Theorem 1.6) and related results to be used in the sequel.

In the remainder of this section, \( S \) will denote a locally inverse Cliffordian semigroup, i.e. \( S \) is a locally inverse semilattice \( Y \) of completely simple semigroups \((S_y : y \in Y)\).

**Lemma 1.1.** If \( E \in E(S_y) \) and \( y \geq z \), there exists precisely one \( e \in E(S_z) \) such that \( E \geq e \). Furthermore, \( S_z E \subseteq E \) and \( R_z E S_z \subseteq R_z \).

**Proof.** If \( y = z \), take \( e = E \). Suppose \( y > z \). Using the proof of [7, Theorem], there exists \( e \in E(S_z) \) such that \( E \geq e \). Let \( g, h \in E(S_y) \) with \( g \leq E \) and \( h \leq E \). Hence, since \( S \) is locally inverse, \( gh = hg \). Thus, \( (hg)(hg) = hhgg = hg \) and, hence, \( hg \in E(S_x) \). Furthermore, \( g(hg) = hg = (hg)g \). Thus, \( hg \leq g \). Thus, since \( S_z \) is completely simple, \( hg : g \). Similarly, \( hg = h \) and, thus, \( g = h \). The proof of the second sentence of the lemma is contained in the proof of [7, Theorem] for \( y > z \). If \( y = z \), apply the Rees theorem [1,
Theorem 3.5].

Let $A \in S_y$ and suppose that $A \in R_E \cap L_F$ where $E, F \in E(S_y)$. Let $e$ and $f$ denote the unique idempotents of $S_z(y \geq z)$ under $E$ and $F$ respectively. We define $A \zeta_{y,z} = eAf$. It is shown in the proof of [7, Theorem] that $\zeta_{y,z}$ is well defined (i.e. $\zeta_{y,z}$ does not depend on the selection of $E$ and $F$).

**Lemma 1.2.** For $y > z$, $\zeta_{y,z}$ is a homomorphism of $S_y$ into $S_z$. Let $A \in S_y$ and $B \in S_z$. If $y > z$, $AB = A \zeta_{y,z}B$. If $z > y$, $AB = A(B \zeta_{z,y})$.

**Proof.** The proof of Lemma 1.2 is contained in the proof of [7, Theorem].

**Lemma 1.3.** If $y \in Y$, $\zeta_{y,y}$ is the identity mapping of $S_y$.

**Proof.** Let $A \in S_y$. Hence, $A \in R_E \cap L_F$ for some $E, F \in E(S_y)$. Let $e$ and $f$ denote the unique idempotents of $S_y$ under $E$ and $F$ respectively. Hence, since $S_y$ is completely simple, $e = E$ and $f = F$, Thus, $A \zeta_{y,y} = eAf = EAF = A$.

Let $yz = y \Lambda z$ in the semilattice $Y$.

**Lemma 1.4.** If $A \in S_y$ and $B \in S_z$, $AB = A \zeta_{y,z}B \zeta_{z,y}$.

**Proof.** Let $A \in L_F$ and $F \in E(S_y)$. Thus, utilizing Lemma 1.2 or 1.3, $AB = A(FB) = A \zeta_{y,y}(FB) = A \zeta_{y,y}F \zeta_{z,y}B = (AF) \zeta_{y,y}B = A \zeta_{y,y}B \zeta_{z,y}$.

**Lemma 1.5.** For $x \geq y \geq z$, $\zeta_{x,y} \zeta_{y,z} = \zeta_{x,z}$.

**Proof.** Let $A \in S_x$ and suppose that $A \in R_E \cap L_F$ for some $E, F \in E(S_z)$. Let $e$ and $f$ denote the idempotents of $S_y$ under $E$ and $F$ respectively. Hence, $A \zeta_{x,y} = eAf$. By Lemma 1.1, $eA \in S_yL_F \subseteq L_f$ and $Af \in R_ES_y \subseteq R_z$. Let $e'$ and $f'$ denote the unique idempotents of $S_z$ under $e$ and $f$ respectively. Hence, $A \zeta_{x,y} \zeta_{y,z} = e' eAf f' = e' A f'$. However, $E \geq e \geq e'$ and $F \geq f \geq f'$. Hence, by Lemma 1.1, $A \zeta_{x,z} = e' A f' = A \zeta_{x,y} \zeta_{y,z}$.

**Theorem 1.6.** Let $\{S_y : y \in Y\}$ be a collection of pairwise disjoint completely simple semigroups indexed by the semilattice $Y$. For each $y, z \in Y$ with $y \geq z$, let $\zeta_{y,z}$ be a homomorphism of $S_y$ into $S_z$ such that

1. $\zeta_{y,y}$ is the identity automorphism of $S_y$. 

STANDARD REGULAR SEMIGROUPS 543
(2) \( \zeta_{x,y,z} \zeta_{y,z} = \zeta_{x,z} \) for \( x \geq y \geq z \) in \( Y \).
Let \( S = \bigcup (S_y: y \in Y) \) and define a product on \( S \) by the rule
(3) \( A \circ B = A_{\zeta_{y,z}} B_{\zeta_{y,z}} \)
where the right hand product is taken in \( S_{yz} \). Then, \( (S, \circ) \) is a locally inverse Cliffordian semigroup.

Conversely, let \( (S, \circ) \) be a locally inverse Cliffordian semigroup. Then, \( S \) is the union of a collection of pairwise disjoint completely simple semigroups \( (S_y: y \in Y) \) indexed by a semilattice \( Y \). For each \( y, z \in Y \) with \( y \geq z \), there exists a homomorphism \( \zeta_{y,z} \) of \( S_y \) into \( S_z \) such that (1) and (2) are valid and the multiplication is given by (3).

Proof. The converse is a consequence of [1, Theorem 4.6] and Lemmas 1.2-1.5. Let us now establish the direct part. Let \( xy = xAy \). Let \( A \in S_x, B \in S_y, \) and \( C \in S_z \). Hence, using (3), the fact \( \zeta_{y,z} \) is a homomorphism, and (2),

\[
A \circ (B \circ C) = A \circ (B_{\zeta_{y,z}} C_{\zeta_{y,z}}) = A_{\zeta_{x,y,z}} ((B_{\zeta_{y,z}} C_{\zeta_{y,z}})_{\zeta_{y,z}})
\]

Similarly, \( (A \circ B) \circ C = (A_{\zeta_{x,y,z}} B_{\zeta_{y,z}}) C_{\zeta_{y,z}} \). Hence \( (A \circ B) \circ C = A \circ (B \circ C) \) by associativity in \( S_{yz} \). By (1) and (3), \( S_y \) is a completely simple subsemigroup of \( S \) for all \( y \in Y \). Thus, \( S_y \) is a Cliffordian semigroup for each \( y \in Y \) by [1, Theorem 2.52]. Hence, \( S \) is Cliffordian. Clearly, \( S \) is a regular semigroup. Finally, let \( E \in E(S_x), f \in E(S_y), \) and \( g \in E(S_z) \) and suppose that \( E \geq f \) and \( E \geq g \). Hence, \( x \geq y \) and \( x \geq z \). Thus, using (3) and (1), \( f = E \circ f = E_{\zeta_{x,y}} f = f \circ E = f(E_{\zeta_{x,y}}) \). Hence, \( E_{\zeta_{x,y}} \geq f(E_{\zeta_{x,y}}, f \in E(S_y)) \). Thus, \( f = E_{\zeta_{x,y}} \) since \( S_y \) is a completely simple semigroup. Similarly, \( g = E_{\zeta_{y,z}} \). Hence, \( f \circ g = f_{\zeta_{y,z}} = E_{\zeta_{z,y}} f \circ g = E_{\zeta_{x,z}} f \circ g = E_{\zeta_{x,y}} E_{\zeta_{z,y}} = E_{\zeta_{x,z}} \). Similarly, \( g \circ f = E_{\zeta_{x,y}} \). Thus, \( g \circ f = f \circ g \), and hence, \( S \) is locally inverse.

Remark. In Theorem 1.6, we term \( \{\zeta_{y,z}: y, z \in Y\} \) the collection of structure homomorphisms of \( S \).

Remark 1.7. In the statement of Theorem 1.6, we may replace “completely simple semigroup” by “left zero semigroup” and “Cliffordian semigroup” by “semilattice of left zero semigroups”. Using Theorem 1.6, a band \( E \) is left normal [17] if and only if \( E \) is a locally inverse semilattice of left zero semigroups. Hence, we have obtained the Yamada-Kimura characterization of left normal bands [17, Theorem 1].

Remark 1.8. In the statement of Theorem 1.6, we may replace “completely simple semigroup” by “right group” and “Cliffordian
The following result will be used in the sequel.

**Proposition 1.9.** Let $S$ be a locally inverse Cliffordian semigroup. Then, $\mathcal{L}$, $\mathcal{R}$, and $\mathcal{H}$ are congruence relations on $S$.

**Proof.** Let $S$ be a locally inverse Cliffordian semigroup. We first show that $\mathcal{L}$ is a congruence relation on $S$. We will apply Theorem 1.6 and its notation. Let $(x, y) \in \mathcal{L}$ in $S$. Hence, $(x, y) \in \mathcal{L} \subset S_u$ for some $u \in Y$. Let $z \in S_u$. Since $\zeta_{u,v}$ is a homomorphism of $S_u$ into $S_{uv}$, $x \zeta_{u,v} \mathcal{L} y \zeta_{u,v}$ in $S_{uv}$. Using the Rees theorem [1, Theorem 3.5], $\mathcal{L}$ is a congruence relation on $S_{uv}$. Hence,

$$z \circ x = \zeta^v_{y,v,v} \zeta^u_{u,v,v} \zeta^u_{y,v,v} = z \circ y.$$ 

Thus, since $\mathcal{L}$ is a right congruence on any semigroup, $\mathcal{L}$ is a congruence on $S$. Similarly, $\mathcal{R}$ is a congruence relation on $S$.

2. Structure theorem for standard regular semigroups (proof of converse) In this section, we will use a sequence of twenty-one lemmas to establish the converse of our structure theorem for standard regular semigroups (Theorem 2.22).

Let $S$ be a standard regular semigroup and let $T$ denote the union of the maximal subgroups of $S$. Hence, $T$ is a semilattice $Y$ of completely simple semigroups $(T_y: y \in Y)$ where $Y$ has a greatest element $y_0$. Let $\{\zeta_{y,z}: y, z \in Y\}$ denote the set of structure homomorphisms of $T$. Let $E_y = E(T_y)$. Select and fix $e_{y_0} \in E_{y_0}$. For each $y \in Y$, define $e_y = e_{y_0} \zeta_{y_0,y}$. Let $S_0 = e_{y_0} S e_{y_0}$.

**Lemma 2.1.** $E(S_0) = \{e_y: y \in Y\}$.

**Proof.** Since $e_y e_y = e_y \zeta_{y_0,y} e_y = e_y$, and, similarly, $e_y e_{y_0} = e_y$, $e_y \in E(S_0)$ for all $y \in Y$. Suppose $f \in E(S_0)$ and $f \in E_y$, say. Hence, $f \leq e_{y_0}$ and $e_y \leq e_{y_0}$ implies $f e_y = e_y f$. Thus, since $T_y$ is completely simple, $f = e_y$.

**Lemma 2.2.** $y \rightarrow e_y$ defines an isomorphism of $Y$ onto $E(S_0)$.

**Proof.** Let $y, z \in Y$. Hence,

$$e_y e_z = e_y \zeta_{y,z} e_z \zeta_{y,z} = (e_{y_0} \zeta_{y_0,y,z} \zeta_{y_0,z}) (e_{y_0} \zeta_{y_0,y,z} \zeta_{y_0,z}) = e_y e_z.$$ 

**Lemma 2.3.** $S_0 = \bigcup (R_y \cap L_z: y, z \in Y)$.

**Proof.** Let $x \in R_y \cap L_z$ where $y, z \in Y$. Using Lemma 2.2, $e_{y_0} x = e_y x$.
$e_v e_x = e_v x = x$ and, similarly, $x e_v = x$. Conversely, if $x \in S$, let $x^{-1}$ denote the unique inverse of $x$ in $S$. Thus, using Lemma 2.1, $x x^{-1} = e$ and $x^{-1} x = e$ for some $y, z \in Y$. Hence, $x \in R_s \cap L_z$.

By the Rees theorem [1, Theorem 3.5], for $y \in Y$, $T_y = G_y \times M_y \times N_y$ where $G_y$ is a group and $M_y$ and $N_y$ are sets under the multiplication $(g, i, j)(h, p, q) = (gf_y(j, p)h, i, q)$ where $(j, p) \to f_y(j, p)$ is a mapping of $N_y \times M_y$ into $G_y$. We note $e_y = (f_y(j_y, i_y)^{-1}, i_y, j_y)$, say, where $f_y(j_y, i_y)^{-1}$ is the inverse of $f_y(j_y, i_y)$ in the group $G_y$. Let $I_y$ denote the set of idempotents of the $S$-class of $T_y$ containing $e_y$ and let $J_y$ denote the $R$-class of $T_y$ containing $e_y$. Hence, $I_y = \{(f_y(j_y, i_y)^{-1}, i_y, j_y); i_y \in M_y\}$ and $J_y = \{(g, i_y, j_y); g \in G$ and $j_y \in N_y\}$. Let $I = \bigcup (I_y; y \in Y)$ and $J = \bigcup (J_y; y \in Y)$.

**Lemma 2.4.** $I$ is a standard regular semilattice $Y$ of left zero semigroups ($I_y; y \in Y$).

**Proof.** Let $a \in I_y$ and $b \in I_z$. Thus, $a \leq e_y$ and $b \leq e_z$. Using Proposition 1.9 and Lemma 2.2, $ab \leq e_{yz}$. Furthermore, $abab = abe_y ab = abe_y b = abb = ab$. Thus, $ab \in I_{yz}$.

**Lemma 2.5.** $J$ is a standard regular semilattice $Y$ of right groups ($J_y; y \in Y$).

**Proof.** Apply Proposition 1.9 and Lemma 2.2.

The next two lemmas are special cases of left-right duals of [14, Lemmas 1.3 and 1.4]. Note our arbitrary representations of the "$e_y$" requires a slight modification in the proof of [14, Lemma 1.3].

**Lemma 2.6.** Every element of $T$ may be uniquely expressed in the form $x = ij$ where $i \in I_y$ and $j \in J_y$ for some $y \in Y$.

If $X$ is a set, $T_X$ will denote the semigroup (iteration) of mappings of $X$ into $X$.

**Lemma 2.7.** There exists a mapping $j \to A_j$ of $J$ into $T_I$ and a mapping $p \to B_p$ of $I$ into $T_J$ such that $I_y A_j \subseteq I_{yz}$ for $j \in J_y$ and $J_y B_p \subseteq J_{yz}$ for $p \in I_y$. If $j \in J$ and $p \in I$, $jp = pA_j jB_p$. Furthermore, $jp R pA_j (eT)$ and $jp \leq jB_p (eT)$.

**Lemma 2.8.** $iA_j = e_{zs}$ for $i \in I_y$ and $j \in J_y$.

**Proof.** First, we show that $A_j = A_z$ for $j \in J_y$. Since $R$ is a congruence relation on $T$, $(j, e_y) \in R$ implies $(jz, e_z) \in R$ for all
i ∈ I. Hence, using Lemma 2.7, (iAj, iAs) ∈ R, for all i ∈ I. Thus, iAj = iAs for i ∈ I. Let i ∈ I, say. Thus, since a_i ∈ I_{rs}, we utilize Lemma 2.7 to obtain (e_i)e_{sr} = e_i = iA_se_{sr}. Thus, by Lemmas 2.7 and 2.6, iA_s = e_s. Since i ≤ e_{rr} and e_{rr} ∈ I, Hence, using Theorem 1.6, e_i = e_i(e_{sr}) = e_{sr}. Thus, iAj = iA_s = e_{sr}.

**DEFINITION** [1, p. 10]. A transformation ρ of a semigroup S is a right translation of S if (ab)ρ = a(bρ) for all a, b ∈ S.

**LEMMA 2.9.** For each i ∈ I, Bi is a right translation of J.

**Proof.** Let r ∈ J, s ∈ J and x ∈ I, say. Hence, utilizing Lemmas 2.5 and 2.7, (rs)x = xA_{rs} (rs)B_x while r(sx) = r(xA_{s}B_x) = xA_{sr} (rB_{s}x)B_x. However, using Lemma 2.8, rB_{x} = rB_{y}. Using Lemma 2.5, re_{yp} ∈ J_{y}. Hence, e_{ycop}(re_{yp}) = re_{yp} = e_{yp}B_rB_{yp}. Hence, using Lemmas 2.7 and 2.6, rB_{yp} = re_{yp}. Thus, using Lemmas 2.7 and 2.6, (rs)B_x = re_{yp}B_x = r(sB_x).

**LEMMA 2.10.** i → Bi is a homomorphism of I into P(J), the semigroup of right translations of J.

**Proof.** Let r, s ∈ I and x ∈ J. Thus, proceeding as in the proof of Lemma 2.9, x(rs) = (rs)A_x B_{rs} and

\[(xr)s = rA_x (xB_s) = (rA_x B_{x})(xB_s).
\]

Thus xB_{rs} = xB_rB_s.

For each y ∈ Y, let H_y denote the maximal subgroup of S containing e_y.

**LEMMA 2.11.** If i ∈ I, and j ∈ J, jB_i ∈ H_y. If j ∈ H_y, jB_i = j.

**Proof.** Let i ∈ I, and j ∈ J. Since jB_i ∈ J, jB_i ∈ H_y. Hence, since jB_i ∈ H_y, jB_i = j. Thus, e_yj = e_yjB_i = e_yB_jB_i = e_yB_j. Hence, since jB_i ∈ H_y, jB_i = j.

**LEMMA 2.12.** If j ∈ J, jB_{e_n} = je_n.

**Proof.** Utilize the proof of Lemma 2.11.

**LEMMA 2.13.** Let X be an inverse semigroup such that the union
of the maximal subgroups of $X$ is a subsemigroup. Then, $\mathcal{H}$ is a congruence relation on $X$.

Proof. Let $H = \bigcup (H_e : e \in E(X))$. Using [1, Theorem 1.7], $H$ is an inverse semigroup which is a union of groups. Hence, $E(H)$ is contained in the center of $H$ by [1, Lemma 4.8]. Let $(a, b) \in \mathcal{H}$. Hence, $aa^{-1} = bb^{-1}$ and $a^{-1}a = b^{-1}b$. Let $c \in S$. Thus,

$$(bc)(bc)^{-1} = bcc^{-1}b^{-1} = ba^{-1}acc^{-1}a^{-1}ab^{-1} = ba^{-1}(ace^{-1}a^{-1})ab^{-1} = ba^{-1}ab^{-1}acc^{-1}a^{-1} = aa^{-1}acc^{-1}a^{-1} = (ac)(ac)^{-1}$$

while $(bc)^{-1}bc = c^{-1}b^{-1}bc = c^{-1}a^{-1}ac = (ac)^{-1}ac$. Hence, $(ac, bc) \in \mathcal{H}$. Similarly, $(ca, cb) \in \mathcal{H}$.

**Lemma 2.14.** $\mathcal{H}$ is a congruence relation on $S_o$.

Proof. Using Lemma 2.3, $\{H_y : y \in Y\}$ is the collection of maximal subgroups of $S_o$. Let $a \in H_y$ and $b \in H_z$, say. Since $a \mathcal{H} e_v, a \xi_{v,y} \mathcal{H} e_y$ and, thus, $a \xi_{y,z} \in H_y$. Similarly, $b \xi_{y,z} \in H_y$. Thus, $ab = a \xi_{y,z} b \xi_{v,y} \in H_{y,z}$. Hence, using Lemma 2.13, $\mathcal{H}$ is a congruence relation on $S_o$.

**Lemma 2.15.** There exists a homomorphism $\phi$ of $S_o$ onto an inverse semigroup $V$ where $E(V) = Y$ and each $\mathcal{H}$-class of $V$ consists of a single element. Furthermore, $(a, b) \in \mathcal{H}(S_o)$ if and only if $a\phi = b\phi$. Thus, if $h_c = c\phi^{-1}, \{h_c : c \in V\}$ is the collection of $\mathcal{H}$-classes of $S_o$.

Proof. Using Theorem 2.14 and [1, Theorem 7.36], $S_{o/\mathcal{H}}$ is an inverse semigroup. Let $a \rightarrow \overline{a}$ denote the natural homomorphism of $S_o$ onto $S_{o/\mathcal{H}}$. Suppose $(\overline{a}, \overline{b}) \in \mathcal{H}(S_{o/\mathcal{H}})$. Hence, $\overline{aa} = \overline{bb}$ and $\overline{a^{-1}a} = \overline{b^{-1}b}$. Thus, $\overline{aa^{-1}} = \overline{bb^{-1}}$ and $\overline{a^{-1}a} = \overline{b^{-1}b}$. Hence, $(aa^{-1}, bb^{-1}) \in \mathcal{H}(eS_o)$ and $(a^{-1}a, b^{-1}b) \in \mathcal{H}(eS_o)$. Thus, $aa^{-1} = bb^{-1}$ and $a^{-1}a = b^{-1}b$. Hence, $(a, b) \in \mathcal{H}$, and, thus, $\overline{a} = \overline{b}$. Thus, each $\mathcal{H}$-class of $S_{o/\mathcal{H}}$ consists of a single element. Using Lemma 2.2 and [1, Lemma 7.34], $\overline{e} \rightarrow y$ defines an isomorphism of $E(S_{o/\mathcal{H}})$ onto the semilattice $Y$. Hence, we may extend this isomorphism to an isomorphism $\lambda$ of $S_{o/\mathcal{H}}$ onto a semigroup $V$ with $E(V) = Y$. For $a \in S_o$, define $a\phi = \overline{a}\lambda$.

For each $c \in V$, select a representative element $v_c \in h_c$. For $y \in Y$, let $v_y = e_v$. Hence, using Lemma 2.15 and its proof, $v_cv_c^{-1} = e_{c^{-1}}$ and $v_c^{-1}v_c = e_{c^{-1}}$ for $c \in V$.

**Lemma 2.16.** Every element of $S$ may be uniquely expressed in the form $iv_j$ where $i \in I_{c^{-1}}$ and $j \in J_{c^{-1}}$. 

Proof. Let \( x \in S \). Hence, \( x \in R_x \cap L_x \) where \( e \in E_x \) and \( f \in E_x \) for some \( y, z \in Y \). Thus, \( (e, i) \in R \) for some \( i \in I_y \) and hence \( (x, i) \in R \). We note that \( e_y D e_x D f \neq \emptyset \). Hence, \( R_x \cap L_x \neq \emptyset \). Thus, using Lemmas 2.3 and 2.15, \( R_x \cap L_x = c_x \) for some \( c \in V \). Thus, \( v_x v^{-1} = e_y \) and \( v^{-1} v_x = e_z \). Hence, \( x = i x = i e_y x = i v_y (v_y^{-1} x) \). We will show that \( v^{-1} x \in T_{c-x} \). Using the proof of [1, Theorem 2.18], there exists an inverse \( x' \) of \( x \) such that \( x' \in R_x \cap L_x \), \( x' = e \), and \( x' x = f \). Let \( x x' = (f_y(s, r)^{-1}, r, s) \) for some \( r \in M_y \) and \( s \in N_y \) and let \( z = (f_x(j_y, r)^{-1}, r, j_y) \). Using the Rees theorem, \( e_x x z = e_y \). Hence, \( e_x = v_x v^{-1} = v_x^{-1} e_x v_x = v_x^{-1} e_x x^z v_x = v_x^{-1} x^z v_x e_x \in v_x^{-1} x S \). However, \( v_x^{-1} x = e_x v_x^{-1} x \in e_x S \). Again, using the Rees theorem, \( x = x x' = x v_x^{-1} x \in x v_x^{-1} x S \). However, \( v_x^{-1} x \in S = S f \). Hence, \( v_x^{-1} x \in R_x \cap L_x \subseteq T \). Since \( e_x v_x^{-1} x = v_x^{-1} x, v_x^{-1} x \in J_x \). Since \( e_x = v_x^{-1} x, z = e_y = (v_y^{-1})^{-1} v_y = c^{-1} v \). Thus, \( v_x^{-1} x \in J_x \). Hence, \( x = i v_x j \) where \( i \in I_{c_x} \) and \( j \in J_{c_x} \). Suppose \( i v_x j = r v_s \) where \( r \in I_{d_x} \) and \( s \in J_{d_x} \). Since \( j R e_{c_x} = e_{c_x} \), \( v_x j R e_{c_x} e_{c_x} = e_{c_x} R e_{c_x} \). Hence, \( i v_x j = i v_s \). Similarly, \( i v_x j = i v_s \). Hence, \( i v_x j = R e_{c_x} \). Thus, \( i R e_{c_x} \). Similarly, \( j R e_{c_x} \). Hence, \( c = d \). Thus, \( i v_x j = i v_s \). Therefore, \( e_{c_x} = i v_x j = e_{c_x} = i v_s \). Hence, \( v_x j = v_s \). Thus, \( j = e_{c_x} j = v_x^{-1} v_x j = v_x^{-1} v_x s = e_{c_x} v_x s = s \).

Lemma 2.17. If \( c, d \in V, v v_d = v c d g(c, d) \) where \( g \) is a function of \( V \times V \) into \( H = \bigcup (H_y : y \in Y) \) such that \( g(c, d) \in H_{(cd)^{-1} cd} \). If \( y, z \in Y, g(y, z) = e_y \).

Proof. Using Lemma 2.16, \( v v_d = v c d j \) where \( i \in I_{c_x} \) and \( j \in J_{c_x} \). We first show \( x = c d \). By the proof of Lemma 2.16, \( i v_x j \in R_x \cap L_x \). However, \( (v_x v_d) (v_x v_d)^{-1} = (e_x v_x v_d)^{-1} \). Hence, using Lemma 2.15, \( (v_x v_d) (v_x v_d)^{-1} \). Similarly, \( (v_x v_d) (v_x v_d) = (e_x v_x v_d) \). Thus, \( x x = (e_x v_x v_d)^{-1} \). Similarly, \( x x = (e_x v_x v_d)^{-1} \). Thus, \( (x, c d) \in \mathcal{H}(V) \). Hence, using Lemma 2.15, \( x = c d \). Thus, \( v v_d = i v c d j \). Let \( j = g(c, d) \). Hence, using Lemma 2.16, \( g \) is a function of \( V \times V \) into \( J \) and \( g(c, d) \in J_{(cd)^{-1} cd} \). Furthermore, \( v v_d = e_{(cd)^{-1} cd} v v_d = e_{(cd)^{-1} cd} i v c d g(c, d) = v c d g(c, d) \). We note that \( g(c, d) = e_{(cd)^{-1} cd} g(c, d) = v c d g(c, d) = v c d v v_d = S_y \). Thus, using Lemma 2.3, \( g(c, d) \in H_{(cd)^{-1} cd} \). To obtain the last statement of the theorem, utilize Lemma 2.2.

If \( u \in J \) and \( s \in V \), define \( u \beta_s = v_s^{-1} v u \).

Lemma 2.18. For \( s \in V, \beta_s \in \text{End} J \) and \( J \beta_s \subseteq H_{s^{-1} s} \). Furthermore, if \( j \in J \) and \( s \in Y, j \beta_s = j e \).

Proof. Let \( j, j_s \in J \). Suppose \( j \in J \) and \( j_2 \in J \). Hence, using Lemma 2.5, \( j \beta_j j_s \beta_s = (v_s^{-1} j v_j) (v_s^{-1} j v_s) = v_s^{-1} j e_s^{-1} (j_z e_s^{-1}) v_s = v_s^{-1} j_2 v_s = (j, j_2) \beta_s \). Hence, \( \beta_s \) is a homomorphism of \( J \) into \( S \). Since is a \( J \)
union of groups, $\beta_\ast$ is a homomorphism of $J$ into $T$. Since $e_\ast \beta_\ast = v_\ast^{-1} e_\ast v_\ast = e_{\ast^{-1} r_{\ast}}$, $j \mathcal{R} e_\ast$ implies $j \beta_\ast e_{\ast^{-1} r_{\ast}}$. Hence, $J_r \beta_\ast \subseteq J_{\ast^{-1} r_{\ast}}$. Thus, $\beta_\ast \in \text{End } J$. Let $j \in J_r$. Thus, $v_\ast^{-1} j v_\ast = v_\ast^{-1} j v_\ast e_{\ast^{-1} r_{\ast}} = v_\ast^{-1} j v_\ast e_{\ast^{-1} r_{\ast}}$. Thus $J_r \beta_\ast \subseteq H_{\ast^{-1} r_{\ast}}$. If $s \in Y$ and $j \in J_r$, $j \beta_\ast e_s = e_s j e_s = j e_s$.

If $j \in H$ and $z \in H$, define $j C_z = z^{-1} j z$. (Using Proposition 1.9 and Lemma 2.2, $H$ is a semilattice $Y$ of the groups $(H_y : y \in Y)$.)

***Lemma 2.19.*** $\beta_c \beta_d = \beta_c \beta_d C_{g(c,d)}$.

**Proof.** Utilizing Lemma 2.17, $j \beta_c \beta_d = v_\ast^{-1} v_\ast^{-1} j v_\ast v_\ast = (v_\ast v_\ast)^{-1} j v_\ast v_\ast = (v_\ast g(c, d))^{-1} j v_\ast g(c, d) = j \beta_c \beta_d C_{g(c,d)}$.

***Lemma 2.20.*** $g(a, bc)g(b, c) = g(ab, c)(g(a, b)\beta_c)$.

**Proof.** Using Lemmas 2.17 and 2.5,

\[ (v_\ast v_\ast) v_\ast = v_\ast ab g(a, b) v_\ast = v_\ast ab g(a, b) e_{cc^{-1}} v_\ast \]

\[ = v_\ast ab e_{cc^{-1}} g(a, b) e_{cc^{-1}} v_\ast = v_\ast ab v_\ast (v_\ast^{-1} g(a, b) v_\ast) \]

\[ = v_\ast ab g(ab, c)(g(a, b)\beta_c) = e_{(ab)\beta_c} e_{cc^{-1}} v_\ast ab g(ab, c)(g(a, b)\beta_c). \]

Using Lemmas 2.17 and 2.18, $g(ab, c)(g(a, b)\beta_c) \in J_{(ab)\beta_c}$. However, if $a, b \in J$, define $a \circ b = ab$. If $a, b \in I$, define $a \circ b = ab$.

***Lemma 2.21.*** $S \cong \{(i, a, j) : a \in V, i \in I_{a^{-1}}$, and $j \in J_{a^{-1}}\}$ under the multiplication $(i, a, j)(u, b, z) = (i \circ e_{(ab)}(ab)^{-1}, ab, g(a, b)^* j B_{ab} \beta^* z)$.

**Proof.** Let $i \in I_{a^{-1}}, j \in J_{a^{-1}}, u \in I_{b^{-1}}$, and $z \in J_{b^{-1}}$. Using Lemmas 2.7, 2.8, and 2.2,

\[ (iv_\ast j)(uv_\ast z) = iv_\ast u A_j j B_u v_\ast z \]

\[ = iv_\ast e_{bb^{-1} a^{-1} a} j B_u v_\ast z \]

\[ = iv_\ast e_{a^{-1} a} b e_{bb^{-1} a} j B_u v_\ast z \]

\[ = iv_\ast e_{bb^{-1} a} v_\ast^{-1} j B_u v_\ast z \]

\[ = iv_\ast e_{bb^{-1} a} j B_u \beta_z \]

\[ = (i \circ e_{(ab)(ab)^{-1}}) v_\ast (g(a, b)^* j B_{ab} \beta^* z). \]

Using Lemmas 2.4, 2.5, 2.7, 2.17 and 2.18, $i \circ e_{(ab)(ab)^{-1}} \in I_{(ab)(ab)^{-1}}$ and $g(a, b)^* j B_{ab} \beta^* z \in J_{(ab)^{-1}ab}$. Hence, using Lemma 2.16, $(iv_\ast j)^\delta = (i, a, j)$ defines an isomorphism of $S$ onto the groupoid given in the statement.
of the lemma.

**Theorem 2.22.** Let $S$ be a standard regular semigroup. Then, $S$ is isomorphic to $(Y, I, J, V, B, \beta, g)$ for some $Y, I, J, V, B, \beta, g$.

**Proof.** Utilize the remark before the proof of Lemma 2.21 and Lemmas 2.2, 2.4, 2.5, 2.10–2.12, 2.15, and 2.17–2.21.

**Remark 2.23.** A semilattice $Y$ is said to be directed from above if $y, z \in Y$ implies there exists $w \in Y$ such that $w \geq y$ and $w \geq z$. Theorem 2.22 is valid if we replace the condition "$Y$" has a greatest element by "$Y$ is directed from above" and "for each $y \in Y$, there exists $e_y \in E_y$ such that $e_y e_z = e_y$ for all $y, z \in Y". Just replace $S$ by the inverse semigroup $\bigcup (e_y S e_y; y \in Y) = \bigcup (R_{ey} \cap L_{ez}; y, z \in Y)$ and note that for $z \leq y$, $e_y e_z = e_z$.

3. Structure theorem for standard regular semigroups (proof of direct half). In this section, we show that $(Y, I, J, V, B, \beta, g)$ is a standard regular semigroup and establish other results to be used later in the sequel.

For brevity, let $S = (Y, I, J, V, B, \beta, g)$.

**Lemma 3.1.** $S$ is a semigroup.

**Proof.** Utilizing (4) and (1), closure is easily established. Let $(i, a, j) = i$ and $(i, a, j) = j$. Let $x = (i, a, j), y = (u, b, z), \text{ and } w = (p, c, q)$. Using the fact $e_r e_s = e_{rs}$ for all $r, s \in Y$ and (4), $((xy)w)_z = (x(yw))$. Utilizing (4), the facts $\beta \in \text{End}(J, *)$ and $i \rightarrow B_i$ is a homomorphism of $(I, \circ)$ into $P(J)$, (3(b), 3(a), 1(c), the fact $e_r e_s = e_{rs}$, 1(b), and 2(a),

$$((xy)w)_z = g(ab, c)^{(g(a, b)^* jB_u \beta \beta^* z)B_v \beta^* q}$$

$$= g(ab, c)^* (g(a, b) \beta \ast (jB_u \beta \beta^* zB_v \beta^* q)$$

$$= g(a, bc)^* g(b, c)^* jB_u \beta \beta^* zB_v \beta^* q$$

$$= g(a, bc)^* g(b, c)^* (g(b, c))^{-1} * (jB_u \beta_b)^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* e_{(bc)}^{-1} jB_u \beta_b^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* jB_u \beta_b^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* jB_u \beta_b^* e_{(bc)^{-1} b} \beta b^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* (jB_u e_{(bc)^{-1} b} \beta b^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* jB_u e_{(bc)^{-1} b} \beta b^* g(b, c)^* zB_v \beta^* q$$

$$= g(a, bc)^* jB_u e_{(bc)^{-1} b} \beta b^* g(b, c)^* zB_v \beta^* q$$

$$= (x(yw))_z.$$
Hence, \((xy)w = x(yw)\).

**Lemma 3.2.** \(E(S) = \{(i, a, j): a \in Y \text{ and } jB_i = e_a\}\).

**Proof.** Let \((i, a, j) \in E(S)\). Using 4, 2(a), 1(a), and 2(c), \(a \in Y\) and \(jB_i \cdot j = j\). Since \(J_a\) is a right group, there exists \(y \in J_a\) such that \(j^*y = e_a\). Hence, using 1(a), \(e_a = j^*y = jB_i^*j^*y = jB_i^*e_a = jB_i\). Conversely, if \(a \in Y\) and \(jB_i = e_a\), using (4), 2(c), and 2(a), \((i, a, j) \in E(S)\).

**Lemma 3.3.** Let \((i, a, j), (u, b, v) \in S\). Then, \((i, a, j)\mathcal{R}(u, b, v)\) if and only if \(i = u\).

**Proof.** First suppose that \(i = u\). Hence, \(a^{-1}a = b^{-1}b\). Let \(x \in I_{(a^{-1}a^{-1}b^{-1}a^{-1}b^{-1})^{-1}}\). Thus, using (1) and the fact \(J_{b^{-1}b}\) is a right group, there exists \(y \in J_{a^{-1}a}\) such that \((g(a, a^{-1}b)b_j^*g(a^{-1}a, b)^*y = v\). Thus, using (4), \((i, a, j)(x, a^{-1}b, y) = (i, b, v)\). Similarly, there exists \(p \in I_{(a^{-1}a^{-1}b^{-1}b^{-1}a^{-1}a^{-1}b^{-1}a^{-1}b^{-1})^{-1}}\) and \(q \in J_{a^{-1}a}\) such that \((i, b, v)(p, b^{-1}a, q) = (i, a, j)\). Thus, \((i, a, j)\mathcal{R}(i, b, v)\). Conversely, suppose that \((i, a, j)\mathcal{R}(u, b, v)\). Using (4), \(i \circ u = u\) and \(u \circ i = i\). Hence, \(i = u\).

**Lemma 3.4.** \(S\) is a regular semigroup.

**Proof.** Let \((i, a, j) \in S\). Using Lemma 3.3, \((i, aa^{-1}, e_{a^{-1}})\mathcal{R}(i, a, j)\). By 2(b), \(e_{a^{-1}}B_i = e_{a^{-1}}\). Hence, using Lemma 3.2, \((i, aa^{-1}, e_{a^{-1}}) \in E(S)\). Thus each \(\mathcal{R}\)-class of \(S\) contains an idempotent.

**Lemma 3.5.** Let \((i, a, j), (w, b, z) \in S\). Then, \((i, a, j)\mathcal{L}(w, b, z)\) if and only if \(a^{-1}a = b^{-1}b\) and \((j, z) \in \mathcal{H}(\varepsilon J_{b^{-1}b})\).

**Proof.** We first show that \((i, a, j)\mathcal{L}(w, b, z)\) if \(a^{-1}a = b^{-1}b\) and \((j, z) \in \mathcal{H}(\varepsilon J_{b^{-1}b})\). Since \((j, z) \in \mathcal{H}(\varepsilon J_{b^{-1}b})\), there exists \(y \in H_{a^{-1}a}\) such that \(y^{-1}j = z\). Since \(g(a, a^{-1}a) \in H_{a^{-1}a}\) by 1(c), there exists \(x \in H_{a^{-1}a}\) such that \(x \cdot g(a^{-1}a, a)^{-1} = z\). Using 1(b), 2(b), 3(a), 2(a), and 1(c), \(g(a^{-1}a, a)^{-1} \cdot x \cdot \beta_{a^{-1}a} \cdot B_i^{-1} \cdot B_i^{-1} \cdot j \cdot y = x \cdot g(a^{-1}a, a)^{-1} \cdot j \cdot y = x \cdot g(a^{-1}a, a)^{-1} \cdot j = z\). Thus, \((e_{a^{-1}a}, a^{-1}a, x \cdot \beta_{a^{-1}a}, \beta_{a^{-1}a})^{-1})(i, a, j) = (e_{a^{-1}a}, a^{-1}a, x \cdot \beta_{a^{-1}a}, \beta_{a^{-1}a})^{-1})(i, a, j) = (w, b, z)\). Hence, \((w, b, (g(b, b^{-1}b)^{-1}) \cdot e_{a^{-1}a}, a^{-1}a, x \cdot \beta_{a^{-1}a}, \beta_{a^{-1}a})^{-1})(i, a, j) = (w, b, z)\). Similarly, there exists \(p \in H_{b^{-1}b}\) such that \((i, a, (g(a, a^{-1}a)^{-1}) \cdot e_{b^{-1}b}, b^{-1}, p \cdot \beta_{b^{-1}b})^{-1})(w, b, z) = (i, a, j)\). Hence, \((i, a, j)\mathcal{L}(w, b, z)\). Conversely, suppose that \((i, a, j)\mathcal{L}(w, b, z)\). Using (4) and (1), \(a^{-1}a = b^{-1}b\) and \((j, z) \in \mathcal{H}(\varepsilon J_{b^{-1}b})\).

**Lemma 3.6.** Let \((i, a, j), (w, b, z) \in S\). Then, \((i, a, j)\mathcal{H}(w, b, z)\) if and only if \(i = w, a = b, \text{ and } (j, z) \in \mathcal{H}(\varepsilon J_{b^{-1}b})\).
Proof. Just note that each \( \mathcal{H} \)-class of \( V \) consists of a single element, and combine Lemmas 3.3 and 3.5.

Remark. Lemmas 3.3 and 3.5 and their proofs were suggested by [16, Lemma 3.2] and its proof.

**Lemma 3.7.** Let \((i, a, j), (w, b, z) \in S\). Then, \((i, a, j) \mathcal{D}(w, b, z) \) if and only if \( a \mathcal{D} b(\varepsilon V) \).

**Proof.** Suppose that \( a \mathcal{D} b(\varepsilon V) \). Hence, there exists \( x \in V \) such that \( aRx \) and \( x \mathcal{L} b \). Hence, \( aa^{-1} = xx^{-1} \) and \( b^{-1}b = x^{-1}x \). Thus, using Lemmas 3.3 and 3.5, \((i, a, j) \mathcal{R}(i, x, z) \mathcal{L}(w, b, z) \). Conversely, if \((i, a, j) \mathcal{D}(w, b, z) \), using (4), \( a \mathcal{D} b(\varepsilon V) \).

**Lemma 3.8.** \( S \) is a bisimple semigroup if and only if \( V \) is a bisimple semigroup.

**Proof.** Apply Lemma 3.7.

**Lemma 3.9** For each \( y \in Y \), let \( T_y = \{(i, y, j) : i \in I_y \text{ and } j \in J_y \} \). Then, \( T_y \) is a completely simple semigroup.

**Proof.** First, we show that \( T_y \) is a simple semigroup. Let \((i, y, j), (u, y, v) \in T_y \). Hence, using (1)(a), (2)(a), and (2)(c), \((i, y, j)(u, y, v) = (i, y, jB^*_y v) \in T_y \). Since \( J_y \) is a right group, there exists \( x \in J_y \) such that \( j^*x = v \). Hence, using (2)(b) and (2)(a),

\[
(u, y, e_y)(i, y, j)(e_y, y, x) = (u, y, v)
\]

Next, we show \( T_y \) is completely simple. Let \( e, f \in E(T_y) \) and suppose that \( e \leq f \). Hence, using Lemma 3.2, \( e = (i, y, j) \) and \( f = (w, y, z) \), say, where \( jB_i = zB^*_w = e_y \). Thus, \((w, y, z)(i, y, j) = (i, y, j) \) implies \( w = i \). Hence, \((i, y, j)(i, y, z) = (i, y, j) \). Thus, \( z = j \) and, hence, \((w, y, z) = (i, y, j) \).

**Lemma 3.10.** Let \( T = \bigcup (T_y : y \in Y) \). Then, \( T \) is a semilattice \( Y \) of the completely simple semigroup \( (T_y : y \in Y) \).

**Proof.** Apply (4), (2)(c), (1)(a), and (2)(a).

**Lemma 3.11.** \( T \) is the union of the maximal subgroups of \( S \).

**Proof.** If \( x \in T_y \), \( x \) is contained in some subgroup of \( S \) (each completely simple semigroup is a union of its subgroups by [1, Theorem 2.52]). Thus, \( x \in H_e \) for some \( e \in E(S) \). Hence, \( T \subseteq X \), the
union of the maximal subgroups of $S$. If $c \in X$, $c \leq e$ for some $e \in E(S)$. Hence, $e = (i, y, j)$ for some $y \in Y$ by Lemma 3.2. Thus, using Lemma 3.6, $c \in T_y$.

**Lemma 3.12.** $T$ is a locally inverse semigroup.

**Proof.** Let $(i, a, j), (u, b, v)$, and $(w, c, z) \in E(S)$ such that $(i, a, j) \geq (u, b, v)$ and $(i, a, j) \geq (w, c, z)$. Hence, $(i, a, j)(u, b, v) = (u, b, v)(i, a, j) = (u, b, v)$. Using Lemma 3.2, $a, b \in Y$, and, hence, $a \geq b$. Since $i \circ e_b = u$, $i \circ u = i \circ (i \circ e_b) = i \circ e_b = u$ while $u \circ i = u \circ (u \circ i) = u$. Hence, $i \geq u$. Using (4), 2(c), 2(a) and 1(a), $jB^*_u v = vB^*_j v = v$. Hence, using the fact $jB_u \in H_b$ and $v \in J_b$, a right group, $jB_u = e_b$. Hence, using Lemma 3.2, $e_b = vB_u = (vB^*_j u)B_u = vB^*_j e_b = vB_i$. Thus, $e_b^* j = v$. Let $\{\varphi_p, q : p, q \in Y\}$ denote the set of structure homomorphisms of $(J, \circ)$. Thus, $e_b^* j \varphi_{a,b} = v$. Hence, $j \varphi_{a,b} = v$. We have shown that $(i, a, j) \geq (u, b, v)$ implies $i \geq u$, $a \geq b$, and $v = j \varphi_{a,b}$. Similarly, $(i, a, j) \geq (w, c, z)$ implies $i \geq w$, $a \geq c$, and $z = j \varphi_{a,c}$. Since $(I, \circ)$ is a locally inverse semigroup, $u \circ w = w \circ u$. Using 2(c), 2(a), and 1(a), $(u, b, v)(w, c, z) = (w \circ e_b, bc, vB^*_u z)$ while $(w, c, z)(u, b, v) = (w \circ e_b, bc, zB^*_u v)$. Let $\{\varphi_p, q : p, q \in Y\}$ denote the set of structure homomorphisms of $(I, \circ)$. Hence, $u \circ w = u \circ e_b \circ w \varphi_{a,b} = w \varphi_{a,b} \circ e_b \circ u \varphi_{a,b} = w \circ e_b$. Similarly, $u \circ w = u \circ e_b$. Hence, $u \circ e_b = w \circ e_b$. Furthermore,

$$vB^*_w z = vB^*_w e_b^* z = vB^*_w B^*_b z = vB^*_w e_b^* z = vB^*_w e_b^* z = e_b^* z = z \varphi_{a,b} .$$

Similarly, $zB^*_u v = \varphi_{a,b}$. Hence, $vB^*_w z = j \varphi_{a,c} \varphi_{a,b} = j \varphi_{a,b} = j \varphi_{a,b} = zB^*_v$. Thus, $(u, b, v)(w, c, z) = (w, c, z)(u, b, v)$.

**Theorem 3.13.** $(Y, I, J, V, B, \beta, g)$ is a standard regular semigroup.

**Proof.** Utilize Lemmas 3.1, 3.4, and 3.10-3.12.

**Theorem 3.14.** $(Y, I, J, V, B, \beta, g)$ is a standard regular semigroup and, conversely, every standard regular semigroup is isomorphic to some $(Y, I, J, V, B, \beta, g)$.

**Proof.** Combine Theorems 2.22 and 3.13.

**Remark 3.15.** Let $J$ and $H$ be as in the statement of Theorem 3.14. Using the proof of [1, Theorem 1.27], Theorem 1.6, and Pro-
position 1.9, $J \cong \bigcup (H_y \times E(J_y); y \in Y)$ where, if $a \in H_y$, $c \in H_z$, $b \in E(J_y)$, and $d \in E(J_z)$, $(a, b)(c, d) = (ac, bd) \in H_y \times E(J_y)$. The multiplications in $H$ and $E(J)$ are given by the corresponding specializations of Theorem 1.6. These specializations yield theorems of Clifford [1, Theorem 4.11] and Yamada and Kimura [17, Theorem 1] respectively.

REMARK 3.16. Let $e_y = (e_y, y, e_y)$. Hence, using (4), 2(c), 2(a), $e_y e_z = e_{yz}$. Thus, if we replace “$Y$ has a greatest element” by “$Y$ is directed from above” in the definition of $(Y, I, J, V, B, \beta, g)$, we obtain the semigroup of Remark 2.23. Hence, Theorem 3.14 with appropriate modifications characterizes these semigroups.

4. Standard regular semigroups of type $\omega Y$. Let $S$ be a regular semigroup such that $T$ is a locally inverse $\omega Y$-semilattice $A$ of completely simple semigroups $(T_{(n, \delta)}: (n, \delta) \in A)$. If $f_{(n, \delta)}^* f_{(m, \lambda)}^* (f_{(n, \delta)}^* f_{(m, \lambda)}^* \in E_{(m, \lambda)} \times E_{(m, \lambda)})$ if and only if $\delta = \lambda$, we term $S$ a standard regular semigroup of type $\omega Y$. If $\delta_0$ is the greatest element of $Y$, $(\epsilon, \delta_0)$ is the greatest element of $A$. We give a characterization of standard regular semigroups of type $\omega Y$(Theorem 4.2). A regular semigroup $S$ such that $T$ is a locally inverse $\omega$-chain of completely simple semigroups $(T_n: n \in N)$ (no further condition) is termed a standard regular semigroup of type $\omega$. We show that $S$ is a simple (bisimple) standard regular semigroup of type $\omega$ if and only if $S$ is a standard regular semigroup of type $\omega Y$ with $Y$ a finite chain (a single element) (Theorem 4.3) (Theorem 4.4). Hence, the structure of these semigroups is given by specializing Theorem 4.2.

To establish Theorem 4.2, we use a more general result on “split” extensions (Theorem 4.1).

Let $S$ be a standard regular semigroup. In the notation of §2, let $\{h_c: c \in V\}$ denote the collection of $\mathbb{H}$-classes of $S_v$. For each $c \in V$, select $v_c \in h_c$. If $v_c v_d = v_{cd}$ for all $c, d \in V$, we term $S$ a split extension of $T$ by $V$.

Let $Y, V, I, J, H,$ and $\{e_i\}$ be as in the definition of $(I, J, V, B, \beta, g)$. Let $i \rightarrow B_i$ be a homomorphism of $(I, \cdot)$ into $P(J)$, and let $v \rightarrow \beta_v$ be a homomorphism of $V$ into $\text{End} (J, *)$ such that (1)(a) $j B_i \in H_{g_{ix}}$ for $j \in J_z$ and $i \in I_y(b)J_z \beta_y \subseteq H_{g_{ix}}$ for $g \in J$ (b) $jB_i = j$ for $j \in H_z$ and $i \in I_z$. Let $(Y, I, J, V, B, \beta)$ denote $\{(i, a, j): a \in V, i \in I_{a^{-1}},$ and $j \in J_{a^{-1}}\}$ under the multiplication (3) $(i, a, j)(u, b, z) = (i \circ e_{ab}(-1))^{-1}, ab, jB_{u \beta_x^* z})$.

THEOREM 4.1. $(Y, I, J, V, B, \beta)$ is a split extension of $T$ by $V$. Conversely, every such semigroup is isomorphic to some $(Y, I, J, V, B, \beta)$. 
Proof. Let \( S = (Y, I, J, V, B, \beta) \). If we let \( g(c, d) = \beta(\beta d)^{-i} \beta d \) for all \( c, d \in V \), it is easily verified that (1)-(4) of the definition of \( (Y, I, J, V, B, \beta, g) \) are valid. Hence, \( S \) is a standard regular semigroup by Theorem 3.14. Let \( y_0 \) denote the greatest element of \( Y \).

Using (2(a) and Lemmas 3.9 and 3.2, \( (e_{y_0}, y_0, e_{y_0}) \in E(T_{y_0}) \). Using (4), (2(a) and the fact \((J, *)\) is locally inverse, \( (e_{y_0}, y_0, e_{y_0})S(e_{y_0}, y_0, e_{y_0}) = \{(e_{a_0}, a, j); a \in V, j \in H_{a_0-1_a} \} \). Thus, using Lemmas 3.6,

\[
h_a = ((e_{a_0}, a, j); j \in H_{a_0-1_a}) .
\]

Let \( v_a = (e_{a_0}, a, e_{a_0}) \). Hence, \( v_av_b = v_{ab} \). Thus, \( S \) is a split extension of \( T \) by \( B \). Conversely, let \( S \) be a standard regular semigroup which is a split extension of \( T \) by \( B \). Hence, using Lemma 2.17, \( g(c, d) = e_{(cd)^{-1}cd} \) for all \( c, d \in V \). Thus, using Theorem 3.14, \( S = (Y, I, J, V, B, \beta, g) \) with \( g(c, d) = e_{(cd)^{-1}cd} \). For brevity, let \( (Y, I, J, V, B, \beta) = U \). Using 3(a), 1(a) and 1(b) of the definition of \( S \), \( c \rightarrow \beta_c \) defines a homomorphism of \( V \) into \( \text{End}(J, *) \), and (4) of the definition of \( S \) reduces to (3) of the definition of \( U \). Hence, \( S \cong U \).

Let \( A \) be an \( \omega Y \)-semilattice. Let \( V = \{(n, k); n, k \in N, \delta \in Y\} \) under the multiplication

\[
(n, k)\delta(r, s) = (n + r - \min(k, r), k + s - \min(k, r))_{f([k, r])}
\]

where \( f([k, r]) = \delta, \eta, \) or \( \delta \eta \) according to whether \( k > r, r > k, \) or \( r = k \). Let \( Y = (A), I, J, H, \) and \( \{e_{[k, \delta]}\} \) be as in the definition of \( (Y, I, J, V, B, \beta) \). Let \( (n, k)_{\delta} \rightarrow \beta_{(n, k)_{\delta}} \) be a homomorphism of \( V \) into \( \text{End}(J, *) \) and let \( \iota \rightarrow \beta_{\iota} \) be a homomorphism of \( (I, \circ) \) into \( P(J) \) such that 1(a) \( jB_i \in H_{(n, k)_{\delta}} \) for \( j \in I_{(n, 2)} \) and \( i \in I_{(n, 3)} \). 1(b) \( J_{(r, \eta)} \beta_{(n, k)_{\delta}} \equiv H_{(r + n - \min(n, r), f([r, n]))} \)\( \beta_{(n, k)_{\delta}} \)\( \equiv H_{(r + n - \min(n, r), f([r, n]))} \)

\[
2(a) hB_{(n, k)_{\delta}}(hB_{(n, k)_{\delta}} = h\beta_{(n, k)_{\delta}} = h^*e_{(n, \delta)} \text{ for } h \in J(b) \text{ } jB_i = j \text{ if } j \in H_{(n, \delta)} \text{ and } i \in I_{(n, \delta)} \). \]

Let \( I_\delta = \bigcup \{I_{(n, \delta)}; n \in N\} \) and let \( J_\delta = \bigcup \{J_{(n, \delta)}; n \in N\} \). Let \( (\omega Y, I, J, B, \beta) \) denote \( \bigcup \{I_\delta \times J_\delta; \delta \in Y\} \) under the multiplication (3): if \( \iota \in I_{(n, \delta)}, j \in J_{(k, \delta)}, u \in I_{(r, \eta)} \) and \( z \in J_{(s, \gamma)} \), \( (i, j)(u, z) = (i \circ e_{[n + r - \min(k, r), f([k, r])]}jB_{[r, s]}^*z) \).

**Theorem 4.2.** \((\omega Y, I, J, B, \beta)\) is a standard regular semigroup of type \( \omega Y \), and conversely every such semigroup is isomorphic to some \((\omega Y, I, J, B, \beta)\).

**Proof.** Let \( S \) be a standard regular semigroup of type \( \omega Y \). Using Lemmas 2.1 and 2.2, \( E(S_\delta) = \{e_{(n, \delta)}; n \in N, \delta \in Y\} \cong A \). Furthermore, \( e_{(n, \delta)} D(e_{(m, 2)} e_{S_0}) \) if and only if \( \delta = \lambda \). Hence, use [15, Lemma 2.1, Theorem 2.3, and Corollaries 2.2 and 2.4] to show \( S \) is a split extension of \( T \) by \( V \) (given in the definition of \((\omega Y, I, J, B, \beta)\)). Hence, \( S \cong (A, I, J, V, B, \beta) \) by Theorem 4.1. Using [15, Corollary
2.4], \( J_{(r, v)} \beta_{(n, k)} \subseteq H_{(r+k - \min (r, n), (r, n))} \) and \( ((n, k)) \beta_{(r, s)} ((n, k)) \beta_{(r, s)}^{-1} = (n + r - \min (k, r), f(k, r)) \). Hence, using Theorem 4.1 and [15, Corollary 2.4], \( S \equiv \{(i, (n, k)) \beta : (n, k) \in V, i \in I_{(n, \delta)}, J \in J_{(k, \delta)} \} \) under the multiplication \( (i, (n, k)) \beta(u, (r, s)) = (i \circ e_{(n + r - \min (k, r), f(k, r))}, (n, k)) \beta_{(r, s)} \). Hence, \( (i, (n, k)) \beta = (i, j) \) defines an isomorphism of \( (A, I, J, V, B, \beta) \) onto \( (\omega, Y, I, J, B, \beta) \). Conversely, consider \( S = (\omega Y, I, J, B, \beta) \). Using [15, Theorem 2.3 and Corollary 2.4], \( V \) is an inverse semigroup with semilattice of idempotents \( A \) and each \( \eta \)-class of \( V \) consists of a single element. Using [15, Corollary 2.4], 1(b) of the definition of \( (A, I, J, V, B, \beta) \) is valid. Hence, \( \zeta^{-1} \) defines an isomorphism of \( S \) onto \( (A, I, J, V, B, \beta) \). By the proof of Theorem 4.1, \( (A, I, J, V, B, \beta) = (A, I, J, V, B, \beta, g) \) with \( g(c, d) = e_{(c, d)}^{-1} c d \). Hence, using [15, Corollary 2.4] and Lemmas 3.2, 3.7, and 3.9-3.12, \( S \) is a standard regular semigroup of type \( \omega Y \).

**Theorem 4.3.** \( S \) is a simple standard regular semigroup of type \( \omega \) if and only if \( S \) is a standard regular semigroup of type \( \omega Y \) with \( Y \) a finite chain \( 0 > 1 > 2 > \cdots > d - 1 \) where \( d \) is a positive integer.

**Proof.** Let \( S \) be a simple standard regular semigroup of type \( \omega \). Hence, \( S \) is a simple semigroup. Thus, using Lemma 2.15 and [15, Lemma 7.5 and Theorem 2.3], \( V \) is the semigroup described in the definition of \( (\omega Y, I, J, B, \beta) \) with \( Y \) the finite chain \( 0 > 1 > 2 \cdots > d - 1 \) where \( d \) is a positive integer. Hence, using Theorem 3.14 (and its proof), [15, Corollary 2.4], Lemmas 3.2, 3.7, and 3.9-3.12, \( S \) is a standard regular semigroup of type \( \omega Y \) with \( Y \) the finite chain \( 0 > 1 > 2 \cdots > d - 1 \) where \( d \) is a positive integer. Conversely, let \( S \) be a standard regular semigroup of type \( \omega Y \) with \( Y \) a finite chain. It is easily seen that \( S \) is a standard regular semigroup of type \( \omega \). We next show that any standard regular semigroup of type \( \omega Y \) is simple. Let \( S = (\omega Y, I, J, B, \beta) \). Let \( i \in I_{(n, \delta)}, j \in J_{(k, \delta)}, u \in I_{(r, \eta)} \), and \( v \in J_{(s, \eta)} \). Let \( q = e_{(n+1, \eta)} B_i \beta_{(n+1, \eta)} j \beta_{(h+1, \eta)} \). Using (1), \( q \in H_{(s, \eta)} \). Hence, since \( J_{(s, \eta)} \) is a right group, there exists \( b \in J_{(s, \eta)} \) such that \( q^* b = v \). Thus, (3), (2(a)), the fact \( c \rightarrow \beta \) is a homomorphism of \( V \) into \( \text{End}(J, *) \), and (1), \((u, e_{(n+1, \eta)} (i, j) (e_{(k+1, \eta)}, b)) = (u, v) \).

If \( A \) is a finite set, \(|A|\) will denote the number of elements of \( A \).

**Theorem 4.4.** \( S \) is a standard regular bisimple semigroup of type \( \omega \) if and only if \( S \) is a standard regular semigroup of type \( \omega Y \) with \(|Y| = 1|\).

**Proof.** Apply Theorem 4.3, Lemma 3.7, and [15, Corollary 2.4].
5. Some other classes of standard regular semigroups. A regular semigroup $S$ is termed standard orthodox ($\mathcal{L}$-unipotent) if $T$ is a locally inverse semilattice $Y$ of rectangular groups (right groups) $(T_y: y \in Y)((J_y: y \in Y))$ where $Y$ has a greatest element. An inverse semigroup $S$ is termed standard inverse if $T$ is a semilattice $Y$ of groups $(H_y: y \in Y)$ where $Y$ has a greatest element. In this section, we give structure theorems for these classes of semigroups.

Let $Y, V, I, J, \{e_b\}, H, \beta, \text{ and } g$ be as in the definition of $(Y, I, J, V, B, \beta, g)$. Furthermore, assume that 1(b), 1(c), 2(c), 3(a), and 3(b) of that definition are valid and that $2(a)$ $g \beta_y = g*e_y$ for $y \in Y$ and $g \in J$. Let $(Y, I, J, V, \beta, g)$ denote $\{(i, a, j): a \in V, i \in I_{a^{-1}}, j \in J_{a^{-1}}\}$ under the multiplication (4)

$$(i, a, j)(u, b, z) = (i \circ e_{(ab)(ab)^{-1}}, ab, g(a, b)*j^\beta z).$$

**Remark 5.1.** $(Y, I, J, V, \beta, g)$ is a standard orthodox semigroup and conversely every standard orthodox semigroup is isomorphic to some $(Y, I, J, V, \beta, g)$.

**Proof.** Let $S$ be a standard orthodox semigroup. It is easily seen that $S$ is standard regular. We apply Theorem 3.14. Let $j \in J$ and $u \in I$. By the proof of Lemma 2.11, $J_B = J_u$. Let $\{\zeta_{y, z}: yz \in Y\}$ denote the set of structure homomorphisms of $T$. Let $j \in J_y$ and $u \in I_z$. Hence, using the fact that $T_{yz}$ is a rectangular group, $ju = j\zeta_{y, z} e_{\zeta_{y, z}} = j\zeta_{y, z} e_{\zeta_{y, z}} = je_z$. Hence $J_B = j*e_z$. Let $j \in J, u \in I_{bb^{-1}}$, and $z \in J_{bb^{-1}}$. Hence, using the fact $\beta_b \in \text{End}(J, \ast)$ and 1(b), $J_B \beta^*_z z = (j*e_{bb^{-1}})\beta^*_z z = j^\beta_z e_{bb^{-1}} z = j^\beta z$. Thus, (4) of Theorem 3.14 reduces to (4) in the definition of $(Y, I, J, V, \beta, g)$.

Conversely, we show $(Y, I, J, V, \beta, g)$ is a standard orthodox semigroup. First, we apply Theorem 3.14 to show that $(Y, I, J, V, \beta, g)$ is a standard regular semigroup. We define $J_B = j^*e_y$ for $j \in J$ and $i \in I_y$. Let $u \in I_y, v \in I_z$, and $j \in J$. Hence $J_B J_B = j^*e_y e_z = j^*e_{yz} = J_B uu$. Let $j, h \in J$ and $i \in I_y$. Hence, $(j^*h) B_i = (j^*h^*e_y = j^*(h^*e_y) = j^*(hB_i)$. Thus, $i \rightarrow B_i$ is a homomorphism of $(I, \circ)$ into $P(J, \ast)$. Let $j \in J_y$ and $i \in I_z$. Let $\{\gamma_{y, z}: y, z \in Y\}$ denote the set of structure homomorphisms of $(J, \ast)$. Hence, for $i \in I_z$, $j B_i = j^*e_z = j^*\gamma_{y, z} e_z \gamma_{y, z}$. However, $e_z \gamma_{y, z} \leq e_z$, and $e_y \leq e_z$. Hence, using the fact that $(J, \ast)$ is locally inverse and $J_{yz}$ is a right group $e_z \gamma_{z, z} = e_{yz}$. Thus, $j B_i = j^*\gamma_{y, z} e_{yz} \in H_{yz}$. Hence, 1(a) of Theorem 3.14 is valid. By definition, $J_B \beta^*_z = j^*e_y$. If $j \in H_y$ and $i \in I_y, j B_i = j^*e_y = j$. Hence, 2(b) of Theorem 3.14 is valid. Let $j \in J, u \in I_{bb^{-1}}$, and $z \in J_{bb^{-1}}$. As above, $j \beta^*_z z = J_B \beta^*_z z$. Thus, (4) of Theorem 3.14 and (4) of the definition of $(Y, I, J, V, \beta, g)$ are equivalent. Hence, using Theorem 3.14, $(Y, I, J, V, \beta, g)$ is a standard regular semigroup. Let $(i, y, j), (u, y, z) \in T_y$.
(note, Lemma 3.9). Hence, using 2(c) and 2(a), \((i, y, j)(u, y, z) = (i, y, j^* z)\). Thus, using [1, Theorem 1.27], \(T_y\) is a rectangular group. Hence, using Lemmas 3.9-3.11, \((Y, I, J, V, \beta, g)\) is a standard orthodox semigroup.

Remark 5.2. By a result of Preston, Yamada, and Clifford, [2, Proposition 1], if \(T\) is a semilattice of rectangular groups, \(T\) is an orthodox semigroup. Conversely, every Cliffordian semigroup which is orthodox is a semilattice of rectangular groups.

Let \(Y, V, J, \) and \(\beta\) be as in Theorem 5.1. For each \(y \in Y\), select \(e_y \in E(J_y)\) such that \(e^*_y e_z = e_y\) for all \(y, z \in Y\). Let \(H_y\) denote the maximal subgroup of \(J_y\) containing \(e_y\). Let \(g\) be as in Theorem 5.1 and assume 1(b), 1(c), 2(a), 2(c), 3(a), and 3(b) of Theorem 5.1 are valid. Let \((Y, J, V, \beta, g)\) denote \(\{(a, j): a \in V, j \in J_{a-1_a}\}\) under the multiplication (4) \((a, j)(b, z) = (ab, g(a, b)^* j\beta^* z)\).

Theorem 5.3. \((Y, J, V, \beta, g)\) is a standard \(\mathcal{L}\)-unipotent semigroup and, conversely, every standard \(\mathcal{L}\)-unipotent semigroup is isomorphic to some \((Y, J, V, \beta, g)\).

Proof. Let \(S\) be a standard \(\mathcal{L}\)-unipotent semigroup. Hence, using [1, Theorem 1.27], \(S\) is standard orthodox. Using Theorem 5.1, \(S = (Y, I, J, V, \beta, g)\). Let \(i \in I_y\). Using Lemma 3.2 and the proof of Lemma 5.1, \((i, y, e_y), (e_y, y, e_y) \in E(S)\). Hence, using Lemma 3.5 and the fact each \(\mathcal{L}\)-class of \(S\) contains precisely one idempotent, \(i = e_y\). Thus, \(I_y = \{e_y\}\) for each \(y \in Y\). Hence, \((e_{a_{x_{a_{i}}}, a, j})\phi = (a, j)\) defines an isomorphism of \((Y, I, J, V, \beta, g)\) onto \((Y, J, V, \beta, g)\). Conversely, we show that \(S = (Y, J, V, \beta, g)\) is a standard \(\mathcal{L}\)-unipotent semigroup. Let \(I_y = \{e_y\}\). Define \(e_y \circ e_z = e_{yz}\) and let \(I = \bigcup (I_y: y \in Y)\). Hence, \((I, \circ)\) is a standard regular semilattice \(Y\) of left zero semigroups \((I_y: y \in Y)\). Then, \(\phi^{-1}\) is an isomorphism of \(S\) onto \((Y, I, J, V, \beta, g)\). Hence, \(S\) is a standard orthodox semigroup. Using Lemmas 3.2 and 3.5, each \(\mathcal{L}\)-class of \(S\) contains precisely one idempotent. Hence, it easily follows that \(S\) is standard \(\mathcal{L}\)-unipotent.

Remark 5.4. A semigroup \(S\) is termed \(\mathcal{L}\)-unipotent if each \(\mathcal{L}\)-class of \(S\) contains precisely one idempotent [13]. Hence, a standard regular semigroup is \(\mathcal{L}\)-unipotent in the sense of [13] if and only if it is standard \(\mathcal{L}\)-unipotent.

Let \(Y, V,\) and \(\beta\) be as in Theorem 5.3. Let \((H, \ast)\) be a semilattice \(Y\) of groups \((H_y: y \in Y)\) and let \(e_y\) denote the identity of \(H_y\) and let \(g\) be as in Theorem 5.3 and assume 1(b), 1(c), 2(a), 2(c), 3(a) and 3(b) of Theorem 5.3 are valid. Let \((Y, H, V, \beta, g)\) denote \(\{(a, j): a \in V, j \in H_{a-1_a}\}\) under the multiplication (4)
(\alpha, \beta)(b, z) = (ab, g(a, b)*j^{*}b^{*}z) .

**Theorem 5.5.** \((Y, H, V, \beta, g)\) is a standard inverse semigroup, and conversely every standard inverse semigroup is isomorphic to some \((Y, H, V, \beta, g)\).

**Proof.** Let \(S\) be a standard inverse semigroup. Then, \(S\) is standard \(\mathcal{L}\)-unipotent. Hence, using Theorem 5.3, \(S \cong (Y, J, V, \beta, g)\). Using Lemma 3.2, \(E(Y, J, V, \beta, g) = \{(y, j); y \in Y, j \in E(J_{y})\}\) Let \(j \in E(J_{y})\). Hence, using 2(c) and 2(a), \((y, j)(y, e_{y}) = (y, e_{y})\) and \((y, e_{y})(y, j) = (y, j)\). Thus, \(j = e_{y}\). Hence, \(J_{y} = H_{y}\) for all \(y \in Y\). Thus, \(S \cong (Y, H, V, \beta, g)\). Conversely, let \(S = (Y, H, V, \beta, g)\). Since \(e_{y}^{*}e_{y} = e_{y}, S\) is standard \(\mathcal{L}\)-unipotent by Theorem 5.3. Using Lemma 3.2, \(E(S) = \{(y, e_{y}); y \in Y\}\). Hence, \(E(S)\) is a semilattice. Thus, it is easily seen that \(S\) is a standard inverse semigroup.

**Remark 5.6.** A characterization of standard orthodox semigroups may be obtained by combining a theorem of M. Yamada [18, Theorem 2] with Theorem 5.5.

6. The congruence \(t\). Let \(S\) be a standard regular semigroup. Let \(t = \{(a, b) \in S^{2}; aa' \in E(T_{y})\) and \(a'a, b'b \in E(T_{z})\) for some \(a' \in \mathcal{J}(a), b' \in \mathcal{J}(b)\), and \(y, z \in Y\}\). We introduced \(t\) in a special case in [12] and used it in subsequent papers (see [15] and [16] for example). We show \(t\) is a congruence on \(S, S/t \cong \mathcal{V}\), and \(\ker t\) (the collection of \(t\)-classes of \(S\) containing idempotents) = \(T\). We note that \(S\) is a regular extension of \(T\) by \(V\) in the sense of Yamada [19].

**Lemma 6.1.** \(\mathcal{J}((i, a, j)) \cap (I_{a^{-1}a} \times \{a^{-1}\} \times J_{a^{-1}a}) \neq \emptyset\).

**Proof.** Let \(y = aa^{-1}\) and let \(u \in I_{a^{-1}a}\). Hence, using (1), \(g(a, a^{-1})^{*}jB_{u}B_{a^{-1}} \in H_{a^{-1}a}\) for \(j \in J_{a^{-1}a}\). There exists \(v \in H_{a^{-1}a}\) such that \(g(a, a^{-1})^{*}jB_{u}B_{a^{-1}v} = e_{y}\). Hence, using (4), \((i, a, j)(u, a^{-1}, v) = (i, y, e_{y})\). However, using 2(b), Lemmas 3.2, 3.3, and 3.5,

\[(i, a, j) = (i, y, e_{y})(i, a, j) = (i, a, j)(u, a^{-1}, v)(i, a, j)\]

while \((u, a^{-1}, v)(i, a, j)(u, a^{-1}, v) = (u, a^{-1}, v)(i, y, e_{y}) = (u, a^{-1}, v)\).

**Lemma 6.2.** \((i, a, j)t(u, b, v)\) if and only if \(a = b\).

**Proof.** Using Lemmas 6.1 and 3.9, there exists \((i, a, j)' \in \mathcal{J}(i, a, j)\) and \((u, b, v)' \in \mathcal{J}(u, b, v)\) such that \((i, a, j)(i, a, j)' \in T_{a^{-1}a}, (u, b, v)(u, b, v)' \in T_{b^{-1}b}, (i, a, j)'(i, a, j) \in T_{a^{-1}a},\) and \((u, b, v)'(u, b, v) \in T_{b^{-1}b}\). Hence,
\((i, a, j)t(u, \delta, v)\) if and only if \(aa^{-1} = bb^{-1}\) and \(a^{-1}a = b^{-1}b\).

**THEOREM 6.3.** \(t\) is a congruence relation on \(S, S/t \cong V,\) and \(\ker t = T.\)

*Proof.* The first two assertions are easily seen. Using Lemmas 3.2, 3.9, and 3.10, \(\ker t = T.\)

**REMARK 6.4.** Using Lemmas 3.9–3.11 and the fact \((i, a, j)\phi = a\) defines a homomorphism of \(S\) onto \(V, S\) is a regular extension of \(T\) by \(V\) in the sense of Yamada [19, page 4]. Thus, using Theorem 6.3, \(S\) is a regular extension of \(T\) by \(S/t.\)
