IRREDUCIBLE OPERATORS WHOSE SPECTRA ARE SPECTRAL SETS

ROBERT OLIN AND JAMES E. THOMSON
In this note those compact subsets of the plane that are the spectra of irreducible subnormal operators are characterized.

In December 1977 John B. Conway presented a colloquium talk at Virginia Tech and asked, "Which compact subsets of the plane are the spectra of irreducible subnormal operators?" If the adjective irreducible is replaced by pure in this question, then Clancey and Putnam [2] have the following answer: A compact set $K$ is the spectrum of a pure subnormal operator if and only if for every open disc $\Delta$ that has a nonempty intersection with $K$, we have $R(K \cap \Delta^-) \neq C(K \cap \Delta^-)$. Similarly, our answer to Conway's question will be a function algebraic characterization. For the basic facts concerning this area we refer to [3] or [10].

If $\mathcal{H}$ is a separable Hilbert space the algebra of continuous operators on $\mathcal{H}$ will be denoted $\mathcal{B}(\mathcal{H})$. An operator $T \in \mathcal{B}(\mathcal{H})$ is irreducible if $\mathcal{H}$ has no nonzero subspace that is invariant under $T$ and its adjoint $T^*$. For the basic facts concerning subnormal operators we refer to [4]. If $T \in \mathcal{B}(\mathcal{H})$ then $\sigma(T)$ will denote the spectrum of $T$.

If $K$ is a compact subset of the plane, $\mathcal{B}(K)$ will denote the collection of rational functions with poles off $K$; the uniform closure of $\mathcal{B}(K)$ in $C(K)$, the algebra of continuous functions on $K$, is denoted $R(K)$. If $\phi$ belongs to the maximal ideal space of $R(K)$, then there exists a point $z \in K$ such that $\phi(f) = f(z)$ for all $f \in R(K)$. Hence the Gleason parts of $R(K)$ form a partition of $K$.

If $T \in \mathcal{B}(\mathcal{H})$ and $K$ is a compact set containing $\sigma(T)$, then $K$ is called a spectral set for $T$ if

\[ \|f(T)\| \leq \|f\|_K \]

for all $f \in \mathcal{B}(K)$. (Here $\|f\|_K$ denotes the sup norm of $f$ on $K$). If $K$ is a spectral set for $T$, it is easy to define $f(T)(\in \mathcal{B}(\mathcal{H}'))$ for all $f \in R(K)$. A basic fact about a subnormal operator $S$ is that $\sigma(S)$ is a spectral set and equality holds in (i) with $K = \sigma(S)$ for all $f \in R(\sigma(S))$.

**Theorem 1.** A compact set $K$ is the spectrum of an irreducible operator $T$ whose spectrum is a spectral set if and only if $R(K)$ has one nontrivial Gleason part $G$ and $G^- = K$. 

431
REMARK. In the sufficiency part of the proof the operator we construct is subnormal. Hence, the theorem answers the question of Conway. For the necessity part of the proof we need two (nontrivial) results and an elementary fact.

Fact. Suppose \( K_i \) is a spectral set for \( T_i \in \mathcal{B}(H) \) and \( K = (\cup K_i)^- \) is compact. Then \( K \) is a spectral set for \( T = \bigoplus T_i \).

We leave the proof to the reader.

**Theorem 2.** (Mlak, Lautzenheiser, Seever). Let \( K \) be a spectral set for \( T \in \mathcal{B}(H) \) and let \( G_1, G_2, \cdots \) be the nontrivial Gleason parts of \( R(K) \). Then \( T = N \oplus (\bigoplus T_i) \), where \( N \) is a normal operator with spectrum contained in the boundary of \( K \) and \( G_i^- \) is a spectral set for \( T_i \). The proof of this and related results can be found in [5, 7, 8, 9].

The following theorem (combined with the fact and Theorem 2) guarantees that if \( K \) is a spectral set for \( T \) with at least two nontrivial Gleason parts \( G_1, G_2 \) for \( R(K) \) such that \( \sigma(T) \cap G_i \neq \emptyset \) \( i = 1, 2 \), then \( T \) has a nontrivial reducing subspace.

**Theorem 3.** (Melnikov). Let \( G_1 \) be a nontrivial Gleason part for \( R(K) \). If \( a \in G_i \backslash G_1 \) then \( a \) is a peak point. In particular, if \( G_2 \) is another Gleason part then \( G_2 \cap G_i^- = \emptyset \).

The proof of this result can be found in [6].

**Proof of Theorem 1.** The only thing left to establish is if \( K \) is a compact set with one nontrivial Gleason part \( G \) and \( G^- = K \), then \( K \) is the spectrum of an irreducible subnormal operator. Choose a sequence \( \{z_n\} \) of points belonging to \( G \) such that \( \{z_n\}^- = K \). Let \( \delta_n \) denote point mass measure at \( z_n \). Fix \( z_0 \in G \).

For each \( z_n \) choose a representing measure \( \lambda_n \) for \( R(K) \) at \( z_0 \) such that \( \delta_n \) is absolutely continuous with respect to \( \lambda_n \) (such a measure can be found by [10, p. 165]). Then

\[
\lambda = \sum_n \frac{\lambda_n}{2^n}
\]

is a representing measure for \( R(K) \) at \( z_0 \) such that the support of \( \lambda \) is \( K \). Let \( H = L^2(\lambda) \), the \( L^2(\lambda) \) closure of \( R(K) \), and let \( S \) be multiplication by \( z \). Clearly \( \sigma(S) = K \) so we need to show \( S \) is irreducible.

Observe first that if \( f \in R(K) \) then
\[ |f(z_0)| = \left| \int f d\lambda \right| = |\langle f, 1 \rangle|. \]

(Here \( \langle , \rangle \) denotes the inner product in \( R^k(\lambda) \).) It is now routine to show that

\[ \langle h_1 h_2, 1 \rangle = \langle h_1, 1 \rangle \langle h_2, 1 \rangle \]

for all \( h_i \in R^k(\lambda) \cap L^\infty(\lambda) \) for \( i = 1, 2 \).

Using the techniques of [12], one can show that the commutant of \( S \) is the set \( \{ M_\psi : \psi \in R^k(\lambda) \cap L^\infty(\lambda) \} \), where \( M_\psi \) denotes multiplication by \( \psi \). Hence, if \( P \) is a projection commuting with \( S \), then \( P = M_\psi \), where \( \psi \) is the characteristic function of a Borel set \( F \).

By (ii) we see that \( \langle f, 1 \rangle \) equals zero or one. We assume that \( \langle f, 1 \rangle = 1 \) (otherwise we work with the projection \( 1 - P = M_{1-f} \)). Hence

\[ 1 = \langle f, 1 \rangle = \int_F d\lambda = \lambda(F). \]

Since \( \lambda \) is a probability measure, \( f = 1 \) almost everywhere; hence \( P = 1 \).

Unfortunately there are no known topological criteria that characterize the sets which are nontrivial Gleason parts of \( R(K) \). (Many necessary topological and measure theoretic facts are known: (1) \( G \) is connected. (2) \( G \) is \( \sigma \)-compact. (3) \( G \) has \( \text{(area)} \) density one at each of its points. (4) \( G \) is \( \text{area connected} \) (consult [6]), etc.) However, the literature contains many interesting examples discussing various properties of these parts. Combining these examples with Theorem 1, one comes up with interesting operator theoretic consequences.

Fix an operator \( T \) whose spectrum is a spectral set. If \( \sigma(T) \) has two components of its interior, say \( U_1 \) and \( U_2 \) such that \( \sigma(T) = (U_1 \cup U_2)^c \) one may ask if \( T = T_1 \square T_2 \) with \( \sigma(T_i) \subset U_i^c \) for \( i = 1, 2 \). However, since there exists a disconnected nontrivial part [10, Examples 26.24 and 26.25] the answer, in general, is no. (The first person to observe this phenomenon was Lautzenheiser in his thesis [5]. In this interesting work he also discusses how Theorem 2 subsumes many other known results.) One may also wonder if it is possible to write \( T = T_1 \square T_2 \) with \( \sigma(T_1) \subset (\text{int } \sigma(T))^c \) and \( \sigma(T_2) \subset (\sigma(T) \setminus \text{int } \sigma(T)) \). Again the answer is no. Let \( D = \{ z : |z| < 1 \} \), \( D_+ = \{ z \in D : \text{Re } z > 0 \} \) and \( D_- = \{ z \in D : \text{Re } z < 0 \} \). Construct a compact set \( F \) from the closed unit disc \( D^- \) by removing pairwise disjoint
open discs $D_t$ from $D_+$ such that $\text{int} (D_+ \cup D_t) = \emptyset$ and $\sum r_t < \infty$ ($r_t$ is the radius of $D_t$). Using Theorem 2 in [11] and Theorem 3 in [1], we can construct $F$ such that zero is not a peak point of $R(F)$. Let $K = G^-$ where $G$ is the nontrivial part of $R(F)$ containing zero. (Note: $G \cap D_+ \neq \emptyset$ and $G \supset D_-$.)

The Supporting Institutions listed above contribute to the cost of publication of this Journal, but they are not owners or publishers and have no responsibility for its content or policies.

Mathematical papers intended for publication in the Pacific Journal of Mathematics should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Please do not use built up fractions in the text of the manuscript. However, you may use them in the displayed equations. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Please propose a heading for the odd numbered pages of less than 35 characters. Manuscripts, in triplicate, may be sent to any one of the editors. Please classify according to the scheme of Math. Reviews, Index to Vol. 39. Supply name and address of author to whom proofs should be sent. All other communications should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints to each author are provided free for each article, only if page charges have been substantially paid. Additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966. Regular subscription rate: $84.00 a year (6 Vols., 12 issues). Special rate: $42.00 a year to individual members of supporting institutions.

Subscriptions, orders for numbers issued in the last three calendar years, and changes of address should be sent to Pacific Journal of Mathematics, P.O. Box 969, Carmel Valley, CA 93924, U.S.A. Old back numbers obtainable from Kraus Periodicals Co., Route 100, Millwood, NY 10546.
