ON THE DECOMPOSITION OF REDUCIBLE PRINCIPAL SERIES REPRESENTATIONS OF $p$-ADIC CHEVALLEY GROUPS

CHARLES DAVID KEYS
ON THE DECOMPOSITION OF REDUCIBLE
PRINCIPAL SERIES REPRESENTATIONS
OF $P$-ADIC CHEVALLEY GROUPS

CHARLES DAVID KEYS

In this paper we study the decomposition of principal series representations of $p$-adic Chevalley groups which are induced from a minimal parabolic subgroup, and determine the structure of the commuting algebras of these representations.

Introduction. Let $G$ be a split reductive $p$-adic group, $T$ a maximal split torus of $G$ and $B = TU$ a minimal parabolic subgroup of $G$. A (unitary) character $\lambda$ of $T$ may be extended trivially across $U$ to define a character of $B$. The induced representation Ind$_G^B \lambda$ is called a (unitary) principal series representation of $G$.

Let $W$ be the Weyl group of $G$ and choose $w \in W$. Then the representations Ind$_G^B \lambda$ and Ind$_G^B w\lambda$ are equivalent. The problem of constructing explicit intertwining operators $a(w, \lambda)$ between Ind$_G^B \lambda$ and Ind$_G^B w\lambda$ has been studied for real semi-simple Lie groups by Kunze and Stein [24, 25, 26] Schiffmann [30], Knapp [14, 15, 16] Knapp and Stein [17, 18, 19, 20, 21, 22] Harish-Chandra [10] and others. For groups defined over a $p$-adic field $\mathfrak{F}$, these operators were first studied for $SL(2)$ by Sally [28], and then for $p$-adic Chevalley groups by Winarsky [36, 37], who used them to determine necessary and
sufficient conditions for $\text{Ind}_{\mathfrak{g}}^g \chi$ to be reducible. A more general study of intertwining operators for $p$-adic groups has been carried out by Harish-Chandra, Silberger and others.

Let $W_1 = \{w \in W | w \chi = \chi \}$. By Bruhat theory [32], the length of the composition series of $\text{Ind}_{\mathfrak{g}}^g \chi$ is bounded by $|W_1|$. Thus $\text{Ind}_{\mathfrak{g}}^g \chi$ is irreducible if $\chi$ is a nonsingular character of $T$, i.e., $W_1 = \{1\}$.

Suppose that $\chi$ is a singular character of $T$ and that $w \chi = \chi$, $1 \neq w \in W$. Then $\alpha(w, \chi)$ is an intertwining operator for $\text{Ind}_{\mathfrak{g}}^g \chi$ which may or may not be scalar. By an unpublished theorem of Harish-Chandra, the operators $\{\alpha(w, \chi) | w \in W_1\}$ span the commuting algebra $C(\chi)$ of $\text{Ind}_{\mathfrak{g}}^g \chi$. However, these operators may not be distinct.

We determine a basis for $C(\chi)$ consisting of a subgroup of these operators. Following Knapp and Stein [14, 19], we write $W_1 = R \ltimes W'$ as a semi-direct product, with $W' = \{w \in W_1 | \alpha(w, \chi) \text{ is scalar}\}$. We show that, with appropriate normalizations, a cocycle condition holds and that $\varphi : \alpha(w, \chi)$ is a homomorphism from $W_1$ to the group of invertible intertwining operators for $\text{Ind}_{\mathfrak{g}}^g \chi$. We then give an elementary proof that the operators $\{\alpha(w, \chi) | w \in R\}$ are linearly independent. This is essentially Silberger’s theorem [33] for the case of minimal parabolics. These facts combined with Harish-Chandra’s theorem imply that $\{\alpha(w, \chi) | w \in R\}$ is a basis of the commuting algebra $C(\chi)$, and further, that $C(\chi)$ is isomorphic to the group algebra $C[R]$.

For complex groups, $\text{Ind}_{\mathfrak{g}}^g \chi$ is always irreducible.

Knapp, in collaboration with Stein, [15, 16] has shown that for real groups, $R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$ with the number of factors of $\mathbb{Z}_2$ bounded by the dimension of $T$. Thus $\text{Ind}_{\mathfrak{g}}^g \chi$ decomposes into $|R|$ components, each occurring with multiplicity one.

For $p$-adic groups, $\text{Ind}_{\mathfrak{g}}^g \chi$ does not always decompose simply. We classify the nontrivial $R$-groups which occur.

**Type $A_n$.** $R$ is abelian and $|R|$ divides $n + 1$. If the largest cyclic subgroup of $R$ has order $m$, then $|R|$ divides $[t^*: (t^*)^m]$. Any finite abelian group with these properties occurs as an $R$-group.

**Type $B_n$.** $R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$ and $|R|$ divides both $2n$ and $[t^*: (t^*)^2]$.

**Type $C_n$.** $R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$ with the number of factors of $\mathbb{Z}_2$ bounded by $n$ and $[t^*: (t^*)^2] - 1$.

**Type $D_n$.** $R$ may be nonabelian. (This general fact was first discovered by Knapp and Zuckerman.)

(a) Suppose $n$ even. Then if $R$ is abelian, $R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$ with the number of factors bounded by $n - 1$ and by $[t^*: (t^*)^2] - 1$. 

If $R$ is nonabelian, $R \cong (Z_2 \times \cdots \times Z_2) \times (Z_3 \times Z_3 \times \cdots \times Z_3)$ with the order of the first factor dividing both $2n$ and $\left\lceil \frac{n}{2} \right\rceil$ and the number of factors of $Z_3$ in the normal subgroup an odd number bounded by $n - 1$ and by $\left\lceil \frac{n}{2} \right\rceil - 1$.

(b) Suppose $n$ is odd. Then if $R$ is abelian, $R \cong Z_2 \times \cdots \times Z_2$ with the number of factors bounded by $n - 1$ and $\left\lceil \frac{n}{2} \right\rceil - 1$, or $R = Z_4$. If $R$ is nonabelian, then $R \cong Z_2 \times (Z_2 \times \cdots \times Z_2)$ with the number of factors of $Z_2$ in the normal subgroup an even number bounded by $n - 3$ and $\left\lceil \frac{n}{2} \right\rceil - 2$.

**Type $E_6$.** $R \cong 1$, $Z_2$, $Z_3$, $Z_5 \times Z_3$ or $Z_9$. Further, $Z_2 \times Z_3$ can occur if and only if $p = 3$ or $3$ divides $q - 1$.

**Type $E_7$.** $R$ may be nonabelian. If so, $R \cong$ dihedral group $D$ of order $8$, or $R \cong D \times Z_2$. $D \times Z_2$ can occur if and only if $p = 2$ or $4$ divides $q - 1$.

If $R$ is abelian, then $R \cong Z_5^n$ with $0 \leq n \leq 4$, $Z_3$, $Z_9$, or $Z_4$. $Z_5^n$ will occur if and only if $\left\lceil \frac{k}{2} \right\rceil \geq 2^n$, $0 \leq n \leq 4$. $Z_4$ occurs if and only if $p = 2$. $Z_3$ and $Z_9$ occur if and only if $p = 3$ or $3$ divides $q - 1$.

**Type $E_8$.** $R$ may be nonabelian. All nonabelian $R$ are conjugate. The nonabelian $R$-group will occur if and only if $\left\lceil \frac{k}{2} \right\rceil \geq 16$. It has order 128, has 65 conjugacy classes, and $R \mod \langle w_0 \rangle$ is abelian.

If $R$ is abelian, then $R \cong Z_5^n$ with $0 \leq n \leq 4$, $Z_3$, $Z_4 \times Z_3$, $Z_9$, $Z_5 \times Z_5$, or $Z_5$. $Z_5^n$ occurs if and only if $\left\lceil \frac{k}{2} \right\rceil \geq 2^{n+1}$, $0 \leq n \leq 4$. $Z_5$ occurs if and only if $p = 2$ or $4$ divides $q - 1$. $Z_4 \times Z_3$ occurs if and only if $p = 2$. $Z_3$ occurs if and only if $\left\lceil \frac{k}{2} \right\rceil \geq 3^{n+1}$, $n = 1$ or $2$. $Z_5$ occurs if and only if $\left\lceil \frac{k}{2} \right\rceil \geq 25$.

**Type $F_4$.** $R \cong Z_2$ or $Z_3$. $Z_5$ can occur as $R$-group if and only if $p = 3$ or $3$ divides $q - 1$.

**Type $G_2$.** $R \cong Z_2$.

The order of $R$ depends on $n$ and on the arithmetic of the field $\mathfrak{k}$, i.e., on the existence of enough multiplicative characters of order $2$, or of order dividing $n + 1$ in the case of type $A_n$ and of order $3$ in the case of type $F_4$.

We note that the methods in this paper also apply to Chevalley groups defined over the reals $R$ and the complex numbers $C$. Since $C^*$ has no nontrivial characters of finite order, $R = \{1\}$ and thus $\text{Ind}_G^R \lambda$ is irreducible for Chevalley groups over $C$. Since $R^*$ has only
one nontrivial character of finite order, we can recover the Knapp-Stein result for Chevalley groups over $\mathbb{R}$. Further $R \cong \mathbb{Z}_2$ or $\{1\}$ except in the case of $D_n$, $n$ even, for which $R \cong \mathbb{Z}_2 \times \mathbb{Z}_2$ can occur [19].

The organization of this paper is as follows. We establish notation and definitions in a preliminary section. In §1 of Chapter 1 we study the normalization and analytic continuation of the intertwining operators $A(w, \lambda)$ and $a(w, \lambda)$ for Macdonald's "groups of $p$-adic type." In §2 we show that with appropriate normalizations the operators $a(w, \lambda)$ are well-defined and establish a cocycle relation for these operators with no condition on the lengths of the Weyl group elements. In §3 we follow Knapp [14, 15] to develop the theory of the $R$-group for $p$-adic Chevalley groups, and show that $C(\lambda) = C[R]$.

Chapter 2 is devoted to the classification of $R$-groups. In each section, we explicitly determine all $R$ which occur for one type of root system, by constructing a list of $\lambda$ and $R$ and showing that every nontrivial $R$-group is conjugate to one on the list.

In Chapter 3 we use the intertwining operators to study the problem of decomposing $\text{Ind}_{\mathfrak{B}}\psi \lambda$ into irreducible components in a "Fourier transform realization" on $L^2(V)$, where $V$ is the unipotent radical of the Borel subgroup opposed to $\mathfrak{B}$. A class of functions is found on which $a(w, \lambda)$ acts as multiplication by a function $M(w, \lambda)$ and we show that the operators $\{a(w, \lambda) \mid w \in R\}$ are linearly independent.

Most of these results appeared in the author's thesis. I would like to express my gratitude and thanks to my advisor, Professor Paul J. Sally, Jr., for his help and guidance.

With some restrictions on the residual characteristic of $k$, independent work of Müller gives partial results describing the $R$-groups which occur for the classical Chevalley groups. See "Integrales d'entrelacement pour un groupe de Chevalley sur un corps $p$-adique" in the Springer Lecture Notes 739.

Preliminaries and definitions. Let $\mathfrak{f}$ be a non-Archemedean local field. We will be concerned mainly with Chevalley groups $G$ defined over $\mathfrak{f}$, although some of our results will apply to the $\mathfrak{f}$-rational points of any reductive algebraic group defined over $\mathfrak{f}$.

Let $dx$ be Haar measure on $\mathfrak{f}$ and $| \cdot |$ the absolute value on $\mathfrak{f}$ defined by $d(ax) = |a| dx$.

Let $O = \{x \in \mathfrak{f} \mid |x| \leq 1\}$ be the ring of integers of $\mathfrak{f}$, $\mathfrak{p}$ a prime element of $O$, and $\mathfrak{p} = \{x \in \mathfrak{f} \mid |x| < 1\}$ the unique nonzero prime ideal of $O$. Then $O/\mathfrak{p}$ is a finite field with $q$ elements, where $q$ is a prime power.
Normalize Haar measure on \( \mathfrak{f} \) so that volume \( (\mathcal{O}) = 1 \). Then \( \mathfrak{p}^n = \{ x \in \mathfrak{f} | |x| \leq q^{-n} \} \) has volume \( q^{-n} \). The collection \( \mathfrak{p}^n, n \in \mathbb{Z} \), forms a fundamental system of neighborhoods at 0 for the topology on \( \mathfrak{f} \), which are both open and compact. Thus \( \mathfrak{f} \) is totally disconnected.

Haar measure on \( \mathfrak{f}^* \) is \( d^*x = |x|^{-1}dx \).

Let \( U_0 = U = \mathcal{O}^* = \{ x \in \mathcal{O} | |x| = 1 \} \) be the units in \( \mathcal{O} \). For each positive integer \( n \), set \( U_n = 1 + \mathfrak{p}^n \). Then the collection \( U_n \) forms a fundamental system of neighborhoods at 1 for \( \mathfrak{f}^* \) consisting of compact and open subgroups.

The additive group of \( \mathfrak{f} \) is self-dual. Fix a nontrivial additive character \( \chi \) of \( \mathfrak{f} \). Then any character of \( \mathfrak{f} \) is of the form \( \chi(ax) = \chi(ax) \). Define the conductor \( \text{cond}(\chi) \) of \( \chi \) to be \( n \) if \( \chi \) is trivial on \( \mathfrak{p}^n \) and nontrivial on \( \mathfrak{p}^{n-1} \).

Since any \( x \in \mathfrak{f}^* \) may be written as \( x = \mathfrak{p}^n u, n \in \mathbb{Z}, u \in U \), we see that \( \mathfrak{f}^* \cong \mathbb{Z} \times U \). Thus \( (\mathfrak{f}^*)^* \cong \mathbb{Z}^* \times U^* \) and any character of \( \mathfrak{f}^* \) is given by \( \lambda(\mathfrak{p}^n u) = |\mathfrak{p}^n| \lambda^*(u) \) where \( s \in \mathbb{C} \), \( \text{Re} s = 0 \), and \( \lambda^* \) is the restriction of \( \lambda \) to the compact group \( U \). We obtain quasi-characters of \( \mathfrak{f}^* \) by \( \lambda(\mathfrak{p}^n u) = |\mathfrak{p}^n| \lambda^*(u) \) where \( s \in \mathbb{C} \). Define \( \text{Re} \lambda = \text{Re} (s) \). \( \lambda \) is unramified if \( \lambda^* = 1 \). Otherwise \( \lambda \) is ramified. Define \( \text{deg}(\lambda) = n \) if \( \lambda \) is trivial on \( U_n \) but nontrivial on \( U_{n-1} \).

A gamma function \( \Gamma(\lambda) \) is associated to each nontrivial multiplicative quasi-character \( \lambda \) \([29, 35]\). If \( \lambda = | \cdot |^{\lambda^*} \) is ramified of degree \( h \), then \( \Gamma(\lambda) = P \cdot V \cdot \left( \frac{\ln |x|}{x} \right)^{\lambda^*} |x|^{-1}dx = c_2 q^{(s-1/n)} \), where \( |c_2| = 1 \) and \( c_2 c_{2-1} = \lambda^*(-1) \). If \( \chi = | \cdot |^{\lambda^*} \) is unramified, then \( \Gamma(\lambda) = P \cdot V \cdot \left( \frac{\ln |x|}{x} \right)^{-1}dx = (1 - q^{-1})/(1 - q^{-s}) \) if \( \text{Re} \lambda > 0 \), and is the analytic continuation of this function into the left half-plane for \( \text{Re} \lambda \leq 0 \), \( s \neq 0 \).

Let \( G \) be a Chevalley group over \( \mathfrak{f} \) \([34]\). Let \( L \) be the semi-simple Lie algebra over \( \mathbb{C} \) which determines \( G \) and \( \mathfrak{h} \) a Cartan sub-algebra. Then \( L = \mathfrak{h} \oplus \sum_{\alpha \in \Phi} L_\alpha \) where \( \alpha \) is a root. Denote the set of roots by \( \Phi \).

Let \( w_\alpha \) denote the reflection in the hyperplane orthogonal to \( \alpha \) in the Euclidean space \( \mathbb{Z}[\Phi] \otimes \mathbb{R} \) and let the Weyl group \( W \) be the group generated by the \( w_\alpha, \alpha \in \Phi \).

\( G \) is generated by subgroups \( U_\alpha = \{ x_\alpha(t) | t \in \mathfrak{f} \}, \alpha \in \Phi \). \( U_\alpha \) carries a natural valuation \( U_{\alpha+n} = \{ x_\alpha(t) | t \in \mathfrak{p}^n \} \).

Let \( w_\alpha(t) = x_\alpha(t)x_{-\alpha}(-t^{-1})x_\alpha(t) \) and \( h_\alpha(t) = w_\alpha(t)w_\alpha(1)^{-1} \) for \( t \in \mathfrak{f}^* \). Let \( T \) be the subgroup generated by all \( h_\alpha(t), \alpha \in \Phi \). Then \( W = N(T)/T \) and \( w_\alpha(t) \) is a coset representative in \( N(T) \) for the reflection \( w_\alpha \).

Fix an ordering on the root system \( \Phi \). This determines a set of positive roots and a set of simple roots which forms a base for
Let $U$ be the subgroup generated by all $U_a$, where $a$ is a positive root.

Then $T$ is a maximal torus of $G$ and $B = TU$ is a Borel subgroup of $G$ with unipotent radical $U$.

For each root $\alpha$, there is a canonical homomorphism $\varphi_\alpha$ from $SL(2, \mathbf{i})$ into the subgroup of $G$ generated by $U_a$ and $U_{-a}$ such that

$$\varphi_\alpha\begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix} = x_\alpha(t), \quad \varphi_\alpha\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = w_\alpha(1),$$

$$\varphi_\alpha\begin{pmatrix} 1 & 0 \\ t & 1 \end{pmatrix} = x_{-\alpha}(t), \quad \text{and} \quad \varphi_\alpha\begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix} = h_\alpha(t).$$

The kernel of $\varphi_\alpha$ is either trivial or $\{\pm I\}$.

If $\lambda$ is a character of $T$, we define for each root $\alpha$ a character $\lambda_\alpha$ of $\mathbf{i}^*$ by $\lambda_\alpha(t) = \lambda(h_\alpha(t))$. The Weyl group $W$ acts on $T$ and thus on characters of $T$. We note that $w\lambda_\alpha(t) = \lambda(w^{-1}h_\alpha(t)) = \lambda(h_{\alpha^{-1}}(t)) = \lambda_{\alpha^{-1}}(t)$. The one-parameter subgroups $h_\alpha(t)$ form a root system $\Phi^\vee$ dual to $\Phi$ in $\text{Hom}(\mathbf{i}^*, T) \otimes \mathbf{R}$. $w$ acts on $\lambda_\alpha$ as $w$ acts on $\alpha$, as $w^{-1}$ acts on $\alpha$. We use this observation to simplify notation and calculations in Chapter 2.

Let $K$ be the subgroup of $G$ generated by $\{x_\alpha(t) | \alpha \in \Phi, t \in \mathbf{C}\}$. Then $K$ is a good maximal compact subgroup of $G$ [4. 27], and there is an Iwasawa decomposition $G = KB = KTU$, nonuniquely.

More generally, suppose $G$ is the group of $\mathbf{i}$-rational points of a reductive algebraic group defined over $\mathbf{i}$. A Borel subgroup $B$ is a maximal connected solvable subgroup of $G$. A parabolic subgroup $P$ is a subgroup of $G$ containing a Borel subgroup. Let $N$ be the unipotent radical of $P$, $A$ a maximal $\mathbf{i}$-split torus in the radical of $P$ and $M = Z_G(A)$. Then $P$ has a Levi decomposition $P = MN$.

$B$ has Levi decomposition $TU$ where $T$ is the centralizer in $G$ of a maximal $\mathbf{i}$-split torus $A$ of $G$. $W = N(A)/Z(A)$ acts on $A$ and thus on $\text{Hom}(A, \mathbf{i}^*)$, which is dually paired over $Z$ with $\text{Hom}(\mathbf{i}^*, A)$. If $G$ is semi-simple, the root system $\Phi = \Phi(G, A)$ spans $\text{Hom}(A, \mathbf{i}^*) \otimes \mathbf{R}$, and we have the dual root system $\Phi^*$ in $\text{Hom}(\mathbf{i}^*, A) \otimes \mathbf{R}$ [1].

Bruhat-Tits theory gives a generating set of valued root data and the existence of good maximal compact subgroups of $G$, for which Iwasawa and Cartan decompositions hold [4, 27].

A topological group $G$ is said to be totally disconnected (t.d.) if there exists a neighborhood basis at $1$ for the topology on $G$ consisting of open compact subgroups. A function on a t.d. group is smooth, or $C^\infty$, if it is locally constant.

Let $G$ be a t.d. group and $V$ a vector space over $\mathbf{C}$. A representation $(\Pi, V)$ of $G$ is a mapping $\Pi: G \to \text{End}(V)$ such that $\Pi(1) = 1$ and $\Pi(xy) = \Pi(x)\Pi(y)$ for all $x, y \in G$. A vector $v \in V$ is smooth if
The decomposition of reducible principal series \( x \mapsto \Pi(x)v \) is a smooth function on \( G \). We say that \( \Pi \) is smooth if every \( v \in V \) is smooth.

If \( H \) is a subgroup of \( G \), define \( V^H = \{ v \in V | \Pi(h)v = v \ \text{for all} \ h \in H \} \). A representation \((\Pi, V)\) of \( G \) is admissible if \( \Pi \) is smooth and \( \dim V^H < \infty \) for any open subgroup \( H \) of \( G \).

A subspace \( W \) of \( V \) is invariant if \( \Pi(x)W = W \) for all \( x \in G \). The representation \((\Pi, V)\) is (algebraically) irreducible if \( V \) has no nontrivial invariant subspaces.

\((\Pi, V)\) is a pre-unitary representation if there is a positive-definite hermitian form on \( V \) which is preserved by all \( \Pi(x), x \in G \). We may take the completion of \( V \) with respect to the inner product defined by this form to obtain a unitary representation of \( G \) on a Hilbert space \( \mathcal{H} \), of which \( V \) is the subspace of smooth vectors.

We also require that \( x \mapsto \Pi(x) \) be continuous for unitary representations. \((\Pi, \mathcal{H})\) is irreducible if there are no nontrivial closed invariant subspaces.

Let \((\Pi, V)\) and \((\Pi', V')\) be representations of \( G \). An intertwining operator between \( \Pi \) and \( \Pi' \) is a linear map \( A: V \rightarrow V' \) with the property that \( A \Pi(x) = \Pi'(x)A \) for all \( x \in G \). \( \Pi \) is equivalent to \( \Pi' \) if \( A \) can be chosen to be a bijection.

Define the commuting algebra of \((\Pi, V)\) to be \( \{ A: V \rightarrow V | A \Pi(x) = \Pi(x)A \ \text{for all} \ x \in G \} \).

If \( \pi, \pi' \) are unitary, we require an intertwining operator \( A \) to be a bounded linear operator. \( \pi \) and \( \pi' \) are (unitarily) equivalent if \( A \) can be chosen to be a unitary operator.

We will use the following criterion for reducibility.

**Theorem.** Suppose \((\pi, V)\) is a unitary representation of \( G \). Then \( \pi \) is irreducible if and only if its commuting algebra is one-dimensional [32].

More detailed introductions to the representation theory of t.d. groups may be found in [6, 11, 13, 32].

**Chapter I**

**Intertwining Operators and the Commuting Algebra**

1. The intertwining operators \( A(w, \lambda) \) and \( a(w, \lambda) \). Let \( P = MN \) be a parabolic subgroup of \( G \) and \((\sigma, V)\) an admissible representation of \( M \), extended trivially across \( N \). Define the representation \( \text{Ind}_P^G \sigma \) to be left translation in the space of functions \( \mathcal{H}_\sigma = \{ f: G \rightarrow V | f \text{ is locally constant and} f(gmn) = \delta_P^{-1}\sigma^{-1}(m)f(g) \text{ for all} g \in G, m \in M, \text{and} n \in N \} \). Since \( G = KP \) with \( K \) compact, \( \text{Ind}_P^G \sigma \) is an admissible representation of \( G \). The factor \( \delta_P^{-1/2} \) is used so that unitary
representations induce to unitary representations. One could also take functions which are square integrable mod \( P \).

From Bruhat theory, one knows that \( \text{Ind}_P^G \sigma \) and \( \text{Ind}_P^G \tau \) have no composition factors in common if \( P \) and \( P' \) are not conjugate in \( G \). Further, \( \text{Ind}_P^G \sigma \) and \( \text{Ind}_P^G \tau \) have a composition factor in common only if there exists a \( w \in W \) normalizing \( M \) such that \( w\sigma \) is equivalent to \( \sigma \). In this case, \( \text{Ind}_P^G \sigma \) is equivalent to \( \text{Ind}_P^G w\sigma \).

Jacquet's theorem states that any irreducible representation of a reductive \( p \)-adic group \( G \) is a subrepresentation of \( \text{Ind}_P^G \sigma \) for some parabolic subgroup \( P \), where \( \sigma \) is a supercuspidal representation of \( M \) \([13, 32]\).

Thus to give a complete list of the irreducible representations of \( G \), one needs to decompose all \( \text{Ind}_P^G \sigma \), with equivalent factors arising only in the case of the equivalent representations \( \text{Ind}_P^G \sigma \) and \( \text{Ind}_P^G w\sigma \).

We study the problem of decomposing the representations \( \text{Ind}_P^G \lambda \), where \( G \) is a Chevalley group over \( \mathfrak{f} \), \( B = TU \) is a Borel subgroup, and \( \lambda \) is a (unitary) character of \( T \).

Let \( W_\lambda = \{ w \in W \mid w\lambda = \lambda \} \) for \( \lambda \) a quasi-character of \( T \). By Bruhat theory, the length of the composition series of \( \text{Ind}_P^G \lambda \) is bounded by \( |W_\lambda| \) if \( \lambda \) is unitary.

Suppose \( w \in W \). Intertwining operators \( A(w, \lambda) \) between \( \text{Ind}_P^G \lambda \) and \( \text{Ind}_P^G w\lambda \) are defined initially for certain nonunitary \( \lambda \). These operators are normalized to define operators \( \alpha(w, \lambda) \) which can be extended by analytic continuation to meromorphic functions in \( \lambda \).

Fix a coset representative \( \bar{w} \) in \( N(T) \) for \( w \). Define \([30, 37]\)

\[
[A(\bar{w}, \lambda)f](g) = \int_{U \cap \bar{w}V \bar{w}^{-1}W} f(guw)du \quad \text{for} \quad f \in H_1.
\]

We remark that if we choose a different coset representative \( \bar{w}' \) for \( w \), then \( \bar{w}^{-1} \bar{w}' \in T \) and the operators differ by a scalar \( \lambda^{-1} \delta_{\bar{w}}^{|\lambda|}(\bar{w}^{-1} \bar{w}') \).

N. Winarsky has shown that \( A(\bar{w}, \lambda)f(g) \) converges absolutely for quasi-characters \( \lambda \) in the domain \( D(w) = \{ \lambda \mid \text{Re} \lambda > 0 \text{ for } \alpha \in \mathcal{R}(w) \} \), where \( \mathcal{R}(w) = \{ \alpha \in \Phi \mid \alpha > 0 \text{ and } w\alpha < 0 \} \), and that \( A(\bar{w}, \lambda) : H_1 \rightarrow H_w \) intertwines \( \text{Ind}_P^G \lambda \) and \( \text{Ind}_P^G w\lambda \). Further, if the condition \( l(w'w') = l(w') + l(w'') \) on lengths holds, then the cocycle condition \( A(\bar{w}' \bar{w}'', \lambda) = A(\bar{w}', \bar{w}'') \circ A(\bar{w}'', \lambda) \) holds \([37]\).

These results are true for \( G \) a reductive \( p \)-adic group. The proofs are as in \([30, 37]\) once we have the following.

**Lemma 1.** Let \( G \) be a reductive \( p \)-adic group. Let \( \text{Re} \lambda = |\lambda| \) and let \( \chi_{\text{Re} \lambda} \) be the \( K \)-fixed vector in \( H_{\text{Re} \lambda} \) defined by \( \chi_{\text{Re} \lambda}(ktu) = \text{Re} (\lambda)^{-1} \rho^{-}(t) \). Suppose \( \text{Re} \lambda > 0 \). Then
\[
\int_{U_{\alpha}} \chi_{\text{Re}}(u\bar{w})du < \infty.
\]

**Proof.** By Bruhat-Tits theory, the derived group of \(G\) possesses a system of valuated root data, with properties which Macdonald has taken as axioms for a "group of \(p\)-adic type" [4, 27].

\(B = TU\) is a minimal parabolic, where \(T\) is now the centralizer of a maximal \(f\)-split torus \(A\) in \(G\). There is a homomorphism \(\nu\) with kernel \(T \cap K\) from \(N(A)\) to the affine Weyl group of \(G\), which is the group generated by reflections in the hyperplanes determined by the set of affine roots \(\{\alpha + r | \alpha \in \Phi, r \in \mathbb{Z}\}\). Let \(Y_r = U_{-a-r}/U_{-a-r+1}\). Then

\[
\int_{U_{\alpha}} \chi_{\text{Re}}(u\bar{w})du = \int_{U_{\alpha}} \chi_{\text{Re}}(\bar{w}v)dv = \int_{U_{\alpha}} \chi_{\text{Re}}(v)dv = \int_{U_{\alpha}} dv + \sum_{r=1}^{\infty} \int_{Y_r} \chi_{\text{Re}}(v)dv.
\]

We may write \(v \in U_{-a-r}\) as \(v = u_1 n u_2\), where \(u_1, u_2 \in U_{a+r} \subset U \cap K\) (\(r\) is a positive integer) and \(\nu(n) = w_{a-r}\). If \(n_1 \in K\) with \(\nu(n_1) = w_{a}\), then \(n_1 n \in T\) and \(\nu(n_1 n) = t_a^r\) where \(t_a\) is the translation \(x \mapsto x + \alpha^r\) in the affine Weyl group. Let \(q_a = (U_{a-1}: U_a)\) and \(q_{a/2} = q_a q_{a/2}\).

Thus

\[
\int_{Y_r} \chi_{\text{Re}}(v) = \int_{Y_r} \chi_{\text{Re}}(u_1 n u_2) = \int_{Y_r} \chi_{\text{Re}}(n) = \int_{Y_r} \chi_{\text{Re}}(n_1 n) = \text{Re} \lambda^{-1} \rho^{-1}(t_a^r) \cdot \text{vol}(Y_r) = \text{Re} \lambda^{-1}(t_a^r)q_a^{-r/2}q_a^{-r/2}[q_a^{r/2}q_a^{-r/2} - q_a^{r/2}q_a^{-r/2}] = \text{Re} \lambda^{-1}(t_a^r)q_a^{-r/2}q_a^{-r/2}q_a^{r/2} = \lambda_a^{-r/2}q_a^{-r/2}q_a^{r/2} = \lambda_a^{-r/2}q_a^{-r/2}q_a^{r/2}.
\]

Thus the sum over \(r\) is a geometric series with common ratio \(\text{Re} \lambda(t_a)^{-2}\), which converges if and only if \(s = \text{Re} \lambda_a > 0\).

The value of the sum is then given by Harish-Chandra's \(c\)-function \(c_\phi(\alpha, s) = c(\alpha/2, s)c(\alpha, s)\). The reader is referred to Macdonald [27].

Let \(V\) be the unipotent radical of the Borel opposed to \(B\). Since \(G = VB\) up to a set of Haar measure zero, functions in \(H_a\) are determined by their values on \(V\) and we may realize \(\text{Ind}_B^G \lambda\) on \(L^2(V)\). Assume that \(\text{Re} \lambda_a > 0\). If \(G\) is a Chevalley group, then \(U_{\alpha}\) is one-dimensional, and a calculation realizing the representation on \(L^2(V)\) via the Fourier transform in \(U_{-\alpha}\), as in the \(\lambda\)-realization of Gelfand, Graev and Pyatetskii-Shapiro [7] or Sally [28] for \(SL(2)\), shows that \(A(\bar{w}_a, \lambda)\) acts as multiplication by \(\lambda_a^{-r/2}q_a^{-r/2}\), where \(\bar{w}_a = w_a(1)\). We may then use the analytic continuation of the gamma function to define the intertwining operator \(A(\bar{w}_a, \lambda)\) for any quasi-character \(\lambda\) such that \(\Gamma(\lambda_a)\) is defined, i.e., for \(\lambda_a \neq 1\).
If we normalize $A(w, X)$ by setting $a(w, X) = (1/\Gamma(Xa))A(w, X)$, then by analytic continuation $a(w, \lambda)$ defines an intertwining operator between $\text{Ind}_F\lambda$ and $\text{Ind}_F w_\lambda$ for all $\lambda$.

Suppose $w \in W$ has length $l$ and $w = w_{a_1} \cdots w_{a_l}$ is a reduced product of basic reflections, $\alpha$ simple. The appropriate normalizing factor for $A(w, \lambda) = A(w_{a_1}, w_{a_2} \cdots w_{a_l} \lambda) \cdots \circ A(w_{a_l}, \lambda)$ is

$$\prod_{i=1}^l \Gamma(w_{a_{i+1}} \cdots w_{a_l} \lambda_{a_i}) = \prod_{\alpha \in R(w)} \Gamma(\lambda_{a}).$$

Denote this product by $\Gamma_w(\lambda)$ and define

$$a(w, \lambda) = \frac{1}{\Gamma_w(\lambda)} A(w, \lambda).$$

An argument similar to that in Winarsky [37] gives the analytic continuation of $A(w, \lambda)$ and $a(w, \lambda)$ in the case of a semi-simple $p$-adic algebraic group.

**Theorem 1.** Let $G$ be a connected semi-simple $p$-adic group and suppose $f \in H_1$ is locally constant. The map $\lambda \mapsto (A(w, \lambda)f)(k)$ of $D(w)$ into $C$ is analytic for $k \in K$. It extends to $C^n$ as a meromorphic function. When $\lambda$ is not a pole of the extension, the operators $A(w, \lambda)$ intertwine the representations $\text{Ind}_F \lambda$ and $\text{Ind}_F w\lambda$.

**Proof.** The unramified part of $\lambda$ is determined by $n$ unramified characters $| \cdot |^s_\alpha$, $\alpha$ simple, each of which is identified with the complex number $s_\alpha$. Multiply this by a representation $\lambda^*$ of $\ker \nu$. Considering $\lambda^*$ fixed and letting the unramified part of $\lambda$ vary, we identify $\lambda$ with a point in $C^n$.

It is enough to prove the theorem in the case $w = w_\alpha$ is a simple reflection. Again, we follow Macdonald [27]. Choose a coset representative $n_\alpha \in K$ for $w_\alpha$ with $\nu(n_\alpha) = w_\alpha$. Write $v \in Y_\alpha = U_{-\alpha+r} \setminus U_{-\alpha+r+1}$ as $v = u_1 n_\alpha^{-1} t_{\alpha} u_2$, with $u_1, u_2 \in U_{\alpha+r}$ and $\nu(t_\alpha)$ translation by $\alpha^*$. Suppose that $f$ is constant on cosets of $U_{-\alpha+m}$ in $K$.

Then

$$A(n_\alpha, \lambda)f(k) = \int_{U_{-\alpha}} f(kn_\alpha v) dv$$

$$= \int_{U_{-\alpha+m-1}} f(kn_\alpha v) dv + \sum_{r=0}^\infty \int_{Y_r} f(kn_\alpha u_1 n_\alpha^{-1} t_{\alpha} u_2)$$

$$= \int_{U_{-\alpha+m-1}} f(kn_\alpha v) dv + \sum_{r=0}^\infty \int_{Y_r} f(kn_\alpha u_1 n_\alpha^{-1} \lambda^{-1} \rho^{-1}(t_\alpha)).$$

But $n_\alpha u_1 n_\alpha^{-1} \in U_{-\alpha+m}$ and $f$ is assumed constant on this. The sum over $r$ is thus
THE DECOMPOSITION OF REDUCIBLE PRINCIPAL SERIES

\[ f(k) \sum_{r=m}^{\infty} \lambda^{-1} \rho^{-1}(t^r_a) \]

\[ 0 \quad \text{if } \lambda_a \text{ is ramified} \]

\[ = \begin{cases} 
 0 & \text{if } \lambda_a \text{ is unramified}.
  \end{cases} \]

For \( \lambda_a \) unramified, this is a geometric series with common ratio \( \lambda(t_a)^{-2} \), which converges if and only if \( \text{Re } \lambda_a > 0 \). In this case the sum is given by

\[ f(k) \cdot \frac{(1 - q_{a}^{-1})(1 + \lambda(t_a)^{-1} q_{a}^{-1}) \lambda(t_a)^{-m}}{1 - \lambda(t_a)^{-2}}. \]

We note that if \( G \) is split, then \( q_{a} = q \) and \( q_{a/2} = 1 \) and the above sum agrees with Winarsky's.

Thus \( \lambda \mapsto A(n_a, \lambda) f(k) \) extends to a meromorphic function of \( s_a \) with simple poles at \( \lambda(t_a) = \pm 1 \) for \( q_{a/2} \neq 1 \) and at \( \lambda(t_a) = 1 \) for \( q_{a/2} = 1 \), if \( | \cdot |_{w_a} \) is unramified, and extends to an analytic function if \( \lambda_a \) is ramified. By analytic continuation, the intertwining relation holds if \( \lambda \) is not a pole of the extension.

If we normalize \( A(\tilde{w}, \lambda) \) by Harish-Chandra's c-function \( c_{\alpha}(\alpha, \lambda_a) \) and \( A(\tilde{w}, \lambda) \) by \( c_{w}(\lambda) = \Pi_{\alpha \in R(w)} c_{\alpha}(\alpha, \lambda_a) \) then \( \lambda \mapsto a(\tilde{w}, \lambda) = (1/c_{w}(\lambda)) A(\tilde{w}, \lambda) \) extends to a meromorphic function on \( C^n \) which is holomorphic in a neighborhood of \( \{ (c_1, \ldots, c_n) \in C^n | \text{Re } c_i = 0, i = 1, \ldots, n \} \) and defines an intertwining operator between \( \text{Ind}_{\beta}^{G} \lambda \) and \( \text{Ind}_{\beta}^{G} w \lambda \) if \( \lambda \) is not a pole.

An argument similar to that of [37] shows that \( \text{Ind}_{\beta}^{G} \lambda \) is reducible if there exists a \( w \in W, w \neq 1 \) with \( w \lambda = \lambda \) such that \( \lambda \) is not a pole of \( c_{w}(\lambda) \).

2. The cocycle condition for \( a(w, \lambda) \). We now choose certain coset representatives for each \( w \in W \). Fix any coset representatives \( n_a \) for the basic reflections \( w_a, \alpha \) simple. Suppose \( w \in W \) has length \( l \) and \( w = w_{a_1} w_{a_2} \cdots w_{a_l} \) is a reduced product of basic reflections. We take \( n_{a_1} n_{a_2} \cdots n_{a_l} \) as the coset representative of \( w \) and define

\[ A(w, \lambda) = A(n_{a_1} n_{a_2} \cdots n_{a_l}, \lambda) \]

\[ a(w, \lambda) = a(n_{a_1} n_{a_2} \cdots n_{a_l}, \lambda). \]

This is well-defined by the following.

**Theorem 1.** Fix coset representatives \( n_a \in N(T) \) for the basic reflections \( w_a, \alpha \) simple. Suppose \( w \) is expressed as a reduced product \( w_{a_1} w_{a_2} \cdots w_{a_l} \) of basic reflections, \( l(w) = l \). Then the coset
representative \( n_{a_1} n_{a_2} \cdots n_{a_i} \) of \( w \) is independent of the expression \( w_{a_1} w_{a_2} \cdots w_{a_i} \).

**Proof.** For Chevalley groups, see page 242 of [34]. For connected reductive \( p \)-adic groups, see page 112 of [4].

We now fix a set of coset representatives as above and write \( A(w, \lambda) \) instead of \( A(\bar{w}, \lambda) \). For the calculations in Chapter 3, we have taken \( n_a = w_a(1) \) as the coset representative for the basic reflection \( w_a, \alpha \) simple.

Recall the cocycle condition \( A(w'w'', \lambda) = A(w', w''\lambda) \circ A(w'', \lambda) \) if \( l(w'w'') = l(w') + l(w''). \) In this case we also have \( \Gamma_{w'w''}(\lambda) = \Gamma_w(\lambda) \Gamma_{w''}(\lambda) \) since \( R(w'w'') = R(w') \cup w''^{-1}R(w') \). Thus \( a(w'w'', \lambda) = a(w', w''\lambda) \circ a(w'', \lambda) \) if \( l(w'w'') = l(w') + l(w'') \).

We will show that with the above choice of coset representatives, the cocycle condition holds for the normalized operators \( a(w, \lambda) \) with no condition on the lengths of \( w' \) and \( w'' \).

We have seen that under the \( \lambda \)-realization in \( U_{-a} \), \( A(w_a, \lambda) \) acts as multiplication by \( \lambda^{-1} \Gamma(\lambda) \). Thus \( A(w_a, w_a \lambda) \circ A(w_a, \lambda) = \Gamma(\lambda_a) \Gamma(\lambda_a^{-1}) \) is scalar and \( a(w_a, w_a \lambda) \circ a(w_a, \lambda) = I \) is the identity.

Thus \( a(w_a, w_a \lambda) \) is the inverse of \( a(w_a, \lambda) \), i.e., the cocycle condition holds in this case.

**Theorem 2.** The cocycle condition \( a(w'w'', \lambda) = a(w', w''\lambda) \circ a(w'', \lambda) \) holds with no condition on the lengths of \( w' \) and \( w'' \).

**Proof.** We first recall that with our choice of coset representatives the operators are well-defined. This is in fact equivalent to the cocycle condition.

The proof is by induction on the length of \( w' \). Suppose \( l(w') = 1 \), say \( w' = w_a, \alpha \) simple. If \( l(w_a w'') = l(w'') + 1 \), then we are done. Otherwise \( l(w_a w'') = l(w'') - 1 \). Suppose \( w'' = w_{\beta_1} w_{\beta_2} \cdots w_{\beta_i} \) is a reduced expression for \( w'' \) as a product of simple reflections. Then by Coxeter's exchange condition [2], \( w'w'' = w_a w_{\beta_1} w_{\beta_2} \cdots w_{\beta_i} = w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_i} \), where \( \beta_j \) is omitted.

Since \( w_a \) has order 2, \( w'' = w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} = w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_1} \), and these are both reduced expressions for \( w'' \). Then since \( a(w'', \lambda) \) does not depend on the reduced expression chosen for \( w'' \), we get

\[
a(w_a, w''\lambda) \circ a(w'', \lambda) \\
= a(w_a, w''\lambda) \circ a(w_a w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_1}, \lambda) \\
= a(w_a, w''\lambda) \circ a(w_a, w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_1}, \lambda) \circ a(w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_1}, \lambda) \\
= I \circ a(w_{\tilde{\beta}_1} \cdots w_{\tilde{\beta}_j} \cdots w_{\tilde{\beta}_1}, \lambda) \\
= a(w_a w'', \lambda) ,
\]
since \( l(w_a w_{\beta_1} \cdots w_{\beta_i} w_{\beta_1} w_{\beta_i} \cdots w_{\beta_i}) = 1 + l(w_{\beta_1} \cdots w_{\beta_i}) \) and \( w_{\beta_1} \cdots w_{\beta_i} \) is a reduced expression for \( w_a w'' \).

Thus the theorem is true if \( w' \) has length 1. Suppose \( w' \) has length > 1 and write \( w' = w_a w_\alpha \) with \( \alpha \) simple and \( l(w_\alpha) = l(w') - 1 \). Then

\[
a(w'w'', \lambda) = a(w_a w_\alpha w'' , \lambda) = a(w_a , w_\alpha w'' \lambda) a(w_\alpha w'' , \lambda) = a(w_a , w_\alpha w'' \lambda) a(w_\alpha , w'' \lambda) a(w'' , \lambda)
\]

by the induction hypothesis,

\[
= a(w_a w_\alpha , w'' \lambda) a(w'' , \lambda) \text{ since } l(w_\alpha) = 1,
\]

\[
= a(w' , w'' \lambda) a(w'' , \lambda).
\]

Thus the cocycle condition is true with no condition on the lengths of \( w' \) and \( w'' \). We remark that one could also use the relations \( (w_a w_\beta)^{\pi(\alpha, \beta)} = 1 \) defining \( W \) as a Coxeter group to prove the cocycle condition.

We note that to prove the theorem, we need only normalize the operators so that \( a(w_a , w_\alpha \lambda) \) is the inverse of \( a(w_a , \lambda) \). For Chevalley groups we may do this with either gamma functions or \( \epsilon \)-functions.

For MacDonald's "groups of \( p \)-adic type" we may use the \( \epsilon \)-functions to do this, at least for unramified \( \lambda \). In any case, \( a(w^{-1} , w_\lambda \lambda) a(w , \lambda) \) is scalar. If \( \lambda \) is unramified and \( f_1 \) is the \( K \)-fixed vector in \( H_1 \) with \( f_1(\epsilon) = 1 \), then \( A(w , \lambda)f_1 = c_\varphi(\lambda)f_{w_\lambda} \) and \( A(w^{-1} , w_\lambda)A(w , \lambda)f_1 = c_{w^{-1}}(\lambda) c_\varphi(\lambda)f_{1} \). So if \( a(w , \lambda) = (1/c_\varphi(\lambda)) A(w , \lambda) \), we see that \( a(w^{-1} , w_\lambda) a(w , \lambda) = I \).

Thus the cocycle relation holds with no condition on lengths for "groups of \( p \)-adic type" and unramified characters \( \lambda \).

Finally, we note that the cocycle condition implies that \( w \mapsto a(w , \lambda) \) is a representation of \( \hat{W}_2 = \{ w \in W \mid w_\lambda = \lambda \} \).

3. The Knapp-Stein \( R \)-group.* We define a subgroup \( R \) of \( \hat{W}_2 \) such that the commuting algebra of \( \text{Ind}_G^G \chi \) is given as the group algebra \( C[R] \). The theory of the \( R \)-group was developed by Knapp and Stein for real semi-simple Lie groups. The following \( p \)-adic analogue is another illustration of Harish-Chandra's "Lefschetz principle," which says that whatever is true for real reductive groups is also true for \( p \)-adic groups.

Let \( \Delta' = \{ \alpha > 0 \mid \lambda_\alpha = 1 \} \). Then \( \pm \Delta' \) is a sub-root system of the root system \( \Phi \).

Let

\[
R = \{ w \in \hat{W}_2 \mid \alpha > 0 \text{ and } \lambda_\alpha = 1 \text{ imply that } w\alpha > 0 \} = \{ w \in \hat{W}_2 \mid w(\Delta') = \Delta' \}.
\]

* Suppose that \( G \) is a Chevalley group.
Let \( W' \) be the reflection group associated to \( \pm \Delta' \), i.e., the group generated by the reflections \( \{ w_\alpha | \alpha \in \Delta' \} \).

**Theorem 1.** \( W_1 \) can be written as a semi-direct product \( W_1 = R \times W' \), where \( R \) and \( W' \) are defined above. Further, \( W' \) is the group \( \{ w \in W_1 | \alpha(w, \lambda) \text{ is scalar} \} \).

**Proof.** First we show that \( W' \leq W_1 \). Let \( \alpha \in \Delta' \) and show that \( w_\alpha \lambda_\beta = \lambda_\beta \) for all roots \( \beta \). But since \( \lambda_\alpha = 1 \), \( w_\alpha \lambda_\beta = \lambda_\beta \). Since \( \lambda_\alpha = 1 \), \( w_\alpha \lambda_\beta = \lambda_\beta \).

Now suppose \( w \in W_1 \) has length \( l \) and write \( w = w_{a_1} \cdots w_{a_l} \) as a reduced product of basic reflections. If \( w \in R \) then we are done. Otherwise there exists \( \alpha \in \Delta' \) with \( w\alpha < 0 \). Then \( \alpha = w_{a_1} \cdots w_{a_{i-1}} (\alpha_i) \) for some \( i, 1 \leq i \leq l \). Let \( r = w_{a_1} \cdots \hat{w}_{a_i} \cdots w_{a_l} \) where \( w_{a_i} \) is omitted. Then

\[
\begin{align*}
w &= w_{a_1} \cdots \hat{w}_{a_i} \cdots w_{a_1} w_{a_1} \cdots \hat{w}_{a_i} \cdots w_{a_1} w_{a_1} \cdots w_{a_1} \\
&= rw_{a_1} \cdots w_{a_{i+1}} w_{a_i} w_{a_{i+1}} \cdots w_{a_1} \\
&= rw_{a_1} \cdots w_{a_{i+1}} (\alpha_i) \\
&= rw_a.
\end{align*}
\]

Then \( w_a \in W' \) since \( \alpha \in \Delta' \). Since \( l(r) < l(w) \) we may use induction on \( l(w) \) to complete the proof that \( W_1 = R \times W' \).

Finally, we show that \( W' = \{ w \in W_1 | \alpha(w, \lambda) \text{ is scalar} \} \). In the \( \chi \)-realization, \( \alpha(w_\alpha, \lambda) \) acts as multiplication by \( \lambda_\alpha^{-1} \), if we use \( w_\alpha(1) \) as coset representative for \( w_\alpha \) and normalize the operator by the gamma function. Thus \( \alpha(w_\alpha, \lambda) = I \) if and only if \( \alpha \in \Delta' \). Then \( \alpha(w, \lambda) = I \) for all \( w \in W' \). The cocycle condition shows that \( w \rightarrow \alpha(w, \lambda) \) is a homomorphism from \( W_1 \) into the group of invertible intertwining operators for \( \text{Ind}_g^\lambda \), and Winarsky [37] shows that \( \alpha(w, \lambda) \) is nonscalar if \( w \in R, w \neq 1 \). These observations complete the proof of the theorem.

We note that Winarsky’s condition for reducibility is essentially that \( R \) is nontrivial.

By an unpublished theorem of Harish-Chandra, the commuting algebra \( C(\lambda) \) of \( \text{Ind}_g^\lambda \) is spanned by \( \{ \alpha(w, \lambda) | w \in W_1 \} \). By the above, it is spanned by \( \{ \alpha(w, \lambda) | w \in R \} \). But these operators are linearly independent, by our calculations in Chapter 3, or by an appeal to Silberger’s theorem [33], which states that

\[
\dim C(\lambda) = |W_1|/|W'|.
\]

Thus the operators \( \{ \alpha(w, \lambda) | w \in R \} \) form a basis for \( C(\lambda) \). Finally, since \( \alpha(w'w'', \lambda) = \alpha(w', \lambda)\alpha(w'', \lambda) \) for \( w' \) and \( w'' \) in \( R \leq W_1 \), we have the following
THEOREM 2. The commuting algebra $C(\lambda)$ of the (unitary) principal series representation $\text{Ind}_F^G \lambda$ is isomorphic to the group algebra $C[R]$.

COROLLARY 1.
(a) $\dim C(\lambda) = |R|$.
(b) The number of inequivalent irreducible components of $\text{Ind}_F^G \lambda$ is equal to the dimension of the center of $C[R]$, which equals the number of conjugacy classes in $R$.
(c) $\text{Ind}_F^G \lambda$ decomposes with multiplicities equal to 1 if and only if $R$ is abelian.
(d) If $C[R] = M_{n_1}(C) \oplus \cdots \oplus M_{n_k}(C)$, then $n_1, \ldots, n_k$ are the multiplicities of the irreducible components of $\text{Ind}_F^G \lambda$.

CHAPTER II
CLASSIFICATION OF THE $R$-GROUPS

The $R$-groups which occur for Chevalley groups of each type $A_n, B_n, C_n, D_n, E_6, E_7, E_8, F_4$ and $G_2$ are determined. They are abelian except in the cases of $D_n$, for which non-abelian $R$ occur for every $n \geq 4$, and in the cases $E_7$ and $E_8$.

The orders of the $R$-groups which can occur depend on $n$ and on the arithmetic of the field $\mathfrak{f}$. Further, the existence of the non-abelian $E_8$ $R$-group depends on the arithmetic of $\mathfrak{f}$.

Let $\lambda$ be a character of $T$ and let
\[ \mathcal{A}' = \{ \alpha > 0 \mid \lambda_\alpha \equiv 1 \} = \{ \alpha > 0 \mid \alpha(w_\alpha, \lambda) \text{ is scalar} \}. \]
Then
\[ R = \{ w \in W \mid \alpha > 0 \text{ and } \lambda_\alpha \equiv 1 \text{ imply that } w\alpha > 0 \} = \{ w \in W \mid w(d') = d' \}. \]

We note that the second definition of $R$ shows that it is a group.

Identify $\lambda_\alpha$ with $\alpha^r$ in the root system $\Phi^r$ dual to $\Phi$ and let $\mathcal{L} = \mathcal{L}^r = \mathbb{Z}[\sum m_\alpha \cdot \alpha^r \mid \prod \lambda_\alpha m_\alpha = 1, m_\alpha \in \mathbb{Z}]$. Then $w \in W$ if and only if $\alpha^r - w\alpha^r \in \mathcal{L}$ for all simple roots $\alpha^r$. $\mathcal{L}$ contains the set $\{ \alpha^r \mid \alpha \in \mathcal{A}' \}$ as positive elements in $\mathcal{L} \cap \Phi^r$, which we sometimes denote by $\mathcal{A}'$.

$w$ acts on $\lambda_\alpha$ as $w$ acts on $\alpha^r$, as $w^{-1}$ acts on $\alpha$. Since $w \in R$ if and only if $w^{-1} \in R$,
\[ R = \{ w \in W \mid \alpha^r \in \Phi^r, \alpha^r \in \mathcal{L} \text{ and } \alpha^r > 0 \text{ imply that } w\alpha^r > 0 \}. \]

We do the calculations to classify $R$ in the root system $\Phi^r$ dual
to $\Phi$. Note that not all of $w'(\alpha^e - w\alpha^e)$, $0 \leq i < \text{ord } w$, can be positive, since their sum is zero. Thus, if $\alpha^e - w\alpha^e \in \mathcal{L} \cap \Phi^e$ for some root $\alpha$, then $w \in R_i$. Note that this condition is invariant under conjugation, replacing $\lambda$ by $w\lambda$, although $R_{w_i}$ may not be equal to $wR_iw^{-1}$.

We use this observation to determine which elements of $W$ can form an $R$-group for some $\lambda \in T^\circ$. Once we have a possible $R$, we look for a character $\lambda$ with $R \leq W_i$ as $R$-group. The existence of such a $\lambda$ depends on the arithmetic of $f$. Our proof explicitly constructs a list of $\lambda$ and $R$ and shows that any nontrivial $R$-group is conjugate under $W$ to one on the list.

We proceed according to the classification of types of root systems [2].

1. Type $A_n$. $\Phi = \Phi^e = \{e_i - e_j | 1 \leq i \neq j \leq n + 1\}$ is self-dual and the Weyl group $W = S_{n+1}$ acts as permutations of the $e_i$.

**Theorem $A_n$.** $R$ is abelian and $|R|$ divides $n + 1$. If the largest cyclic subgroup of $R$ has order $m$, then $|R|$ divides $[\mathfrak{t}: (\mathfrak{t}^*)^\circ] = \text{order of the subgroup of } (\mathfrak{t}^*)^\circ \text{consisting of characters of order dividing } m$.

**Conventions.** We identify $e_i - e_j \in \Phi^e$ with the character $\lambda_{e_i - e_j}$ and consider $Z[\Phi^e]/\mathcal{L}$ as a subgroup of $(\mathfrak{t}^*)^\circ$ by the map $\sum m_\alpha \alpha^e \mapsto \prod \lambda_\alpha^{m_\alpha}$.

**Lemma 1.** $w \mapsto e_i - e_{wi}$ is an injective homomorphism from $R$ into $(\mathfrak{t}^*)^\circ$, independent of $i$.

**Proof.** Let $w \in W_1$. Then $e_i - e_j = w(e_i - e_j) = e_{wi} - e_{wj}$ implies that $e_i - e_{wi} = e_j - e_{wj}$, so that the map is independent of $i$. Note that $=$ means congruence mod $\mathcal{L}$ and that we have used the fact that $w \in W_1$ if and only if $\alpha^e - w\alpha^e \in \mathcal{L}$ for all $\alpha \in \Phi^e$.

Let $w, w' \in W_1$. Then $e_i - e_{w' i} = e_i - e_{w'i} + e_{w'i} - e_{w'w'i} = e_i - e_{wi} + e_{wi} - e_{wi}$ shows that the map is a homomorphism.

If $w \neq 1$ then we may replace everything by a conjugate to assume that $w1 \neq 1$. Then if $e_i - e_{wi} \in \mathcal{L}$, we have $e_i - e_{wi} \in \mathcal{L}'$ and $w^{-1}(e_i - e_{wi}) < 0$, so that $w \in R$. Thus the map is injective on $R$.

Thus $R$ is isomorphic to a subgroup of $(\mathfrak{t}^*)^\circ$ and is abelian. Further, if the largest cyclic subgroup of $R$ has order $m$, then any element of $R$ has order dividing $m$ and the image of $R$ is contained in the subgroup of characters of $\mathfrak{t}^*$ of order dividing $m$. Thus $|R|$ divides $[\mathfrak{t}: (\mathfrak{t}^*)^\circ]$.

Since $R$ is abelian, $\text{Ind}_R^G \lambda$ decomposes simply. This is shown for $G = \text{SL}(n, f)$ by Howe and Silberger [12].
We note that if $\mathfrak{t} = R$, then the image of $R$ is a finite subgroup of $(R^*)^\wedge$, so has order 1 or 2 [17].

**Lemma 2.** The stabilizer of any $e_i$ in $R$ is trivial. Thus $|R|$ divides $n + 1$.

**Proof.** Suppose $w \in R$ fixes some $i$. Then $e_i - e_{wi} = 0$ and the image of $w$ under the above map is trivial. Thus $w = 1$. So the action of $R$ partitions $\{1, 2, \ldots, n + 1\}$ into orbits of cardinality $|R|$ and $|R|$ divides $n + 1$.

Note that any finite subgroup of $(\mathfrak{t}^*)^\wedge$ with order dividing $n + 1$ is the image of some $R$-group.

**Remark.** The homomorphism $w \mapsto e_i - e_{wi}$ is suggested by the following. In Chapter 3 we realize $\text{Ind}^G_\mathfrak{t} \lambda$ and $\alpha(w, \lambda)$ on $L^i(V)$. We exhibit a class of functions in $L^i(V)$ on which $\alpha(w, \lambda)$ acts as multiplication by $M(w_{si}, \lambda) = \lambda^{-1}_\alpha$ in the $U_{-\alpha}$ coordinate, $\alpha$ simple. Then $\alpha(w, \lambda) = \alpha(w_{si} \cdots w_{s1}, \lambda)$ acts as multiplication by the function $M(w, \lambda) = M(w_{si}, w_{s2} \cdots w_{si} \lambda) \cdots M(w_{s1}, \lambda)$.

Then $w \mapsto M(w, \lambda)$ is a homomorphism, as is $w \mapsto M(w, \lambda)$ evaluated at some $U_{-\alpha}$, $\alpha$ simple. The above map $M(w, \lambda)$ is evaluated at $U_{-\alpha}$, $\alpha = e_1 - e_2$.

We note that the linear independence of distinct characters of $\mathfrak{t}^*$ implies that the $M(w, \lambda)$ evaluated at $U_{-\alpha}$ are linearly independent for $w \in R$, and therefore the operators $\{\alpha(w, \lambda) | w \in R\}$ are linearly independent.

2. **Type $B_n$.** $\Phi = \{\pm e_i \pm e_j, \pm e_k | 1 \leq i < j \leq n, 1 \leq k \leq n\}$. The dual root system $\Phi^* = \{\pm e_i \pm e_j, \pm 2e_k | 1 \leq i < j \leq n, 1 \leq k \leq n\}$ is type $C_n$. The Weyl group $W \cong S_n \ltimes Z_n^*$ acts on $\Phi$ and $\Phi^*$ by permutations and sign changes on the $e_i$.

**Theorem $B_n$.** $R \cong Z_2 \times \cdots \times Z_2$ with $|R|$ dividing both $2n$ and $|f^*| = (f^*)^2$.

Suppose $w = sc \in W_2$ with $s \in S_n$ and $c \in Z_2$. We may replace $w$ by a conjugate under $S_n$ to assume the cycles in $s$ consist of consecutive integers, and then by a conjugate by a sign change to assume that $c$ changes the sign of at most one $e_i$ in each orbit of $s$.

**Lemma 1.** If $w = sc \in R$, then a nontrivial cycle of $s$ can not have only one sign change associated to it.

**Proof.** We may assume the cycle is $(kk + 1 \cdots n - 1n)$, $k < n$,
and that the sign change is on $2e_n$. Repeated application of $w^{-1}$ sends $e_{n-1} - e_n$ to $e_k - e_{k+1}$, which $w^{-1}$ then sends to $-e_n - e_k$. Thus $e_k + e_{n-1} \in \mathcal{L}$.

If $k = n - 1$, then $2e_{n-1} \in \mathcal{L} \cap \Phi^v$. But then $2e_{n-1} > 0$ and $w^{-1}(2e_{n-1}) = -2e_n < 0$ contradicts $w \in R$.

Otherwise $k < n - 1$ and $e_k + e_{n-1} \in \mathcal{L} \cap \Phi^v$. But then $e_k + e_{n-1} > 0$ and $w(e_k + e_{n-1}) = w(e_{k+1} + e_n) = e_{k+2} - e_k < 0$ contradicts $w \in R$.

**Lemma 2.** Any nontrivial cycle of $s \in S_n$ must be a transposition if $w = sc \in R$.

**Proof.** We may assume that the cycle is $(k \cdots n - 1 \ n)$, and by the above lemma, that there are no sign changes associated to this cycle, i.e., $c(2e_i) = 2e_i$ for $k \leq i \leq n$.

Then $w(e_{n-1} + e_n) = e_n + e_k$ implies that $e_k - e_{n-1} \in \mathcal{L}$. If $k < n - 1$, then $e_k - e_{n-1} \in \mathcal{L} \cap \Phi^v$, with $e_k - e_{n-1} > 0$ and $w^{-1}(e_k - e_{n-1}) = e_n - e_{n-2} < 0$, contradicting $w \in R$. Thus $k = n - 1$ and the cycle is a transposition.

By the two lemmas, any $w = sc \in R$ is conjugate to a product of disjoint transpositions and sign changes, so $w^2 = 1$ and $R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2$. Further, no such $w \neq 1$ can fix an $e_i$. This follows by the argument for type $A_n$ if $s \neq 1$. If $s = 1$, $w = c \neq 1$ changes the sign of some $e_j$. Then if $w(e_i) = e_i$ we have $e_j - e_i - w(e_j - e_i) = 2e_j \in \mathcal{L} \cap \Phi^v$. But then $2e_j > 0$ and $w(2e_j) < 0$ contradicts $w \in R$.

Thus $R$ permutes $\{ \pm e_i | 1 \leq i \leq n \}$ with stabilizer $\{ \pm e_i \} = \{1\}$, so $|R|$ divides $2n$.

We now have that any $w \in R$ is conjugate to one of $1$, $(12) (34) \cdots (n - 1 \ n)$, $(12) \cdots (k - 1 \ k)c_{k+1} \cdots c_n$, or $c_1 c_2 \cdots c_n$, where $c_i$ is the sign change on $e_i$.

If we evaluate $M(w, \lambda)$ at $U_{-s}$, $\alpha = e_i - e_j$, we get the homomorphism $c_1 \cdots c_n \mapsto 2e_i$ (i.e., $\lambda e_i$) and $w \mapsto e_i - we_i$ if $w = sc$ with $s(i) \neq i$. We note that none of these characters can be trivial if $w \in R$, so $w \mapsto e_i - we_i$ is an injective homomorphism from $R$ into the group of characters of $\mathfrak{f}^*$ generated by those of order 2. Thus $|R|$ divides $[\mathfrak{f}^*: (\mathfrak{f}^*)^\circ]$.

Of course, one may directly check that $w \mapsto e_i - we_i$ is independent of $i$ and is an injective homomorphism from $R$ into the subgroup $\mathbb{Z}[\Phi^v] / \mathcal{L}$ of $(\mathfrak{f}^*)^\circ$ without reference to $M(w, \lambda)$.

We note that if $\mathfrak{f} = R$, then $|R| = 1$ or 2, and that if $\mathfrak{f}$ is non-Archimedean with odd residual characteristic, then $|R| = 1, 2,$ or 4.

3. **Type $C_n$.** $\Phi = \{ \pm e_i \pm e_j, \pm 2e_k | 1 \leq i < j \leq n, 1 \leq k \leq n \}$. The dual root system $\Phi^v = \{ \pm e_i \pm e_j, \pm e_k | 1 \leq i < j \leq n, 1 \leq k \leq n \}$ is type $B_n$. The Weyl group $W \cong S_n \times \mathbb{Z}_2^n$ acts on $\Phi$ and $\Phi^v$ by permutations and sign changes on the $e_i$. 
Theorem \( C_n \). \( R \cong \mathbb{Z}_2 \times \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2 \) with the number of factors of \( \mathbb{Z}_2 \) bounded by \( n \) and by \( [\mathfrak{B}^\ast:(\mathfrak{B}^\ast)^2]-1 \).

Suppose \( w = sc \in W_2, s \in S_n \) and \( c \in \mathbb{Z}_2^n \). We may replace \( w \) by a conjugate under a sign change to assume that \( c \) changes the sign of at most one \( e_i \) in each orbit of \( s \).

Lemma 1. Suppose \( w = sc \in R, s \in S_n, c \in \mathbb{Z}_2^n \). Then \( s = 1 \).

Proof. If \( s \) has a nontrivial cycle, by conjugation we may assume it is \((k \cdots n - 1 n)\) and that \( c \) changes the sign of at most one \( e_i \) in the corresponding orbit.

Suppose \( c(e_i) = e_i \) for \( k \leq i < n \) and \( c(e_n) = -e_n \). Then \( w^{-1}(e_n) = e_{n-1} \) implies that \( e_{n-1} - e_n \in \mathbb{Z}^n \cap \Phi^\ast \). But repeated application of \( w^{-1} \) sends \( e_{n-1} - e_n \) to \( e_k - e_{k+1} \), which \( w^{-1} \) sends to \(-e_n - e_k < 0 \), contradicting \( w \in R \).

Now suppose \( c(e_i) = e_i \) for \( k \leq i \leq n \). Then \( w^{-1}(e_n) = e_{n-1} \) and \( e_{n-1} - e_n \in \mathbb{Z}^n \cap \Phi^\ast \). But then \( w(e_{n-1} - e_n) = e_n - e_k < 0 \) contradicts \( w \in R \).

Thus \( s = 1 \) if \( w = sc \in R \), and \( R \) is contained in the group of sign changes in \( W \). Hence \( R \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2 \) with the number of factors bounded by \( n \).

Let \( w \in R \). By conjugation we may assume that \( w = c_h c_{k+1} \cdots c_n \).

Lemma 2. If \( c_h c_{k+1} \cdots c_n \in R \), then \( c_i \in R, k \leq i \leq n \).

Proof. \( e_i \) and \( e_i - e_j, k \leq i \neq j \leq n \), correspond to characters of order 2, and \( \mathbb{Z}^\ast \) contains \( Z[2e_i | k \leq i \leq n] \). Then \( \alpha = c_i \alpha \in \mathbb{Z}^\ast \) for all simple \( \alpha \), so \( c_i \in W_i, k \leq i \leq n \). Since \( R(c_i) \subseteq R(c_h \cdots c_n) \) does not intersect \( A \), we have that \( c_i \in R \). (Recall that \( R(w) = \{ \alpha > 0 | w \alpha < 0 \} \).

Thus any \( R \) is conjugate to \( \langle c_h, c_{k+1}, \cdots, c_n \rangle \) for some \( k, 1 \leq k \leq n \), taking \( c_h \cdots c_n \) above with as many sign changes as possible.

Note that each \( e_i \) corresponds to a character of order 2, \( k \leq i \leq n \), and that these characters must be distinct, since \( e_i - e_j \) does not correspond to the trivial character, \( k \leq i \neq j \leq n \). Conversely, we may define a character \( \lambda \) with \( R \)-group \( \langle c_h, c_{k+1}, \cdots, c_n \rangle \) by assigning a distinct character of order 2 to each \( e_i, k \leq i \leq n \).

Thus the number of factors of \( \mathbb{Z}_2 \) in \( R \) is bounded by \( [\mathfrak{B}^\ast:(\mathfrak{B}^\ast)^2]-1 \).

Note that there can be more reducibility in the case of type \( C_n \) than in the case of type \( B_n \).

\( B_n \): \(|R| \) divides \( 2n \) and \( [\mathfrak{B}^\ast:(\mathfrak{B}^\ast)^2] \).

\( C_n \): \(|R| \) divides \( 2^n \) and \( 2^{[\mathfrak{B}^\ast:(\mathfrak{B}^\ast)^2]-1} \).
If \( t = R \), we again get \(|R| = 1 \) or \( 2 \).

4. Type \( D_n \). \( \Phi = \Phi^* = \{ \pm \epsilon_i \pm \epsilon_j | 1 \leq i < j \leq n \} \) is self-dual and the Weyl group \( W \cong S_n \rtimes Z_2^{n-1} \) acts as permutations and even sign changes on the \( \epsilon_i \).

**Theorem** \( D_n \).

(a) Suppose \( n \) is even. Then if \( R \) is abelian, \( R \cong Z_2 \times \cdots \times Z_2 \) with the number of factors bounded by \( n - 1 \) and by \([t^* : (t^*)^2] - 1 \). If \( R \) is nonabelian, then \( R \cong (Z_2 \times \cdots \times Z_2) \rtimes (Z_2 \times Z_2 \times \cdots \times Z_2) \) with the order of the first factor dividing both \( 2n \) and \([t^* : (t^*)^2] \), and the number of factors of \( Z_2 \) in the normal subgroup an odd number bounded by \( n - 1 \) and \([t^* : (t^*)^2] - 1 \).

(b) Suppose \( n \) is odd. Then if \( R \) is abelian, \( R \cong Z_4 \times \cdots \times Z_2 \) with the number of factors of \( Z_2 \) bounded by \( n - 1 \) and \([t^* : (t^*)^2] - 1 \), or \( R = Z_4 \). If \( R \) is nonabelian, \( R \cong Z_4 \rtimes (Z_2 \times \cdots \times Z_2) \) with the number of factors of \( Z_2 \) in the normal subgroup an even number bounded by \( n - 3 \) and \([t^* : (t^*)^2] - 2 \).

The actions on the normal factors of the semi-direct products are described explicitly in the course of the proof.

**Lemma 1.** Suppose \( w = sc \in R, s \in S_n \) and \( c \in Z_2^{n-1} \). Then \( s^2 = 1 \).

**Proof.** Suppose \( s \) has a cycle of length \( \geq 3 \). Replacing \( w \) by a conjugate under \( S_n \), we may assume the cycle is \((k k + 1 \cdots n)\), \( k < n - 1 \). Then by conjugating \( w \) by a sign change, we may assume that \( c \) changes the sign of at most 2 of the \( \epsilon_i \) in each orbit of \( s \).

If \( c \) involves no sign changes on \( \epsilon_1, \cdots, \epsilon_n \), then \( w^{-1}(e_{n-1} + e_n) = e_{n-2} + e_{n-1} \) implies that \( e_{n-1} - e_n \in \Delta' \). But then \( w(e_{n-2} - e_n) < 0 \) contradicts \( w \in R \).

If \( c \) involves only one sign change on \( \epsilon_k, \cdots, \epsilon_n \), we may suppose it is on \( \epsilon_n \). Then \( w(e_{n-1} + e_n) = e_n - e_k \) implies that \( e_k + e_{n-1} \in \Delta' \). But then \( w^2(e_k + e_{n-1}) = e_{k+2} - e_k < 0 \) contradicts \( w \in R \).

Finally, if there are two sign changes involved, we may suppose they are on \( e_{n-1} \) and \( e_n \). Then \( w(e_{n-1} - e_n) = -e_n + e_k \) implies that \( e_k - e_{n-1} \in \Delta' \). But then \( w^{-1}(e_k - e_{n-1}) = -e_n - e_{n-2} < 0 \) contradicts \( w \in R \).

Note that \( w = sc \in R, s^2 = 1 \) implies that \( w^2 = (scs^{-1})c \) is a sign change in \( R \) and thus \( w^3 = 1 \). If we let \( R' \) be the group of sign changes in \( R \), then \( R' \leq R \) and \( R/R' \cong Z_2 \times \cdots \times Z_2 \).

**Lemma 2.** Suppose \( c_k \epsilon_{k+1} \cdots \epsilon_n \in R \) with \( k > 1 \). Then \( R \) contains all even sign changes on \( \{ \epsilon_k, \epsilon_{k+1}, \cdots, \epsilon_n \} \).
Proof. If $k > 1$, then $c_k c_{k+1} \cdots c_n \in R$ if and only if $e_i - e_j$ corresponds to a character of order 2 for $k \leq i < j \leq n$, and $e_{n-1} \pm e_n$ correspond to the same character. Then $c_i c_{i+1} \in W$ and $R(c_i c_{i+1}) \subseteq R(c_k c_{k+1} \cdots c_n)$ imply that $c_i c_{i+1} \in R$, for $k \leq i < n$.

Thus $R'$ consists of all even sign changes on $\{e_k, \ldots, e_n\}$, and $|R'| \leq 2^{n-1}$.

Further, since the characters corresponding to $e_i - e_j$ are non-trivial for $k \leq i < j < n$, the characters corresponding to $e_i - e_n$ are distinct, $k \leq i < n$. Thus $|\Lambda'| \geq \binom{n}{2} - 1$.

Now, suppose $w = sc \in R$ with $s \neq 1$. By conjugation we may assume $s = (12)(34) \cdots (k-1 k)$ with $k \leq n$. Then $c(e_i) = -e_i$ for $k < i \leq n$; first, we may assume $c(e_k) = +e_k$ by conjugation by $c_k c_n$ if necessary. Then if $c(e_i) = e_i$ for some $k < i \leq n$, $w(e_k - e_i) = e_{k-1} - e_i$ would imply $e_{k-1} - e_k \in \delta'$. But then $w(e_{k-1} - e_k) < 0$ contradicts $w \in R$. Thus we have shown

**Lemma 3.** $\text{stab}_R(\pm e_i) \subseteq \delta'$.

Further, any element of order 2 in $R$ is conjugate to one of $c \in Z_2^{n-1}$, $(12)(34) \cdots (n-1 n)$, $(12)(34) \cdots (n-1 n)c_{n-1} c_n$, or $(12) \cdots (k-1 k)c_{k+1} \cdots c_n$ for some $k$. Any element of order 4 in $R$ is conjugate to $(12)(34) \cdots (m-1 m)c_k c_{k+2} \cdots c_m c_{m+2} \cdots c_n$ for some $m$, $k$ with $2 \leq k \leq m \leq n$, where the sign change changes the sign of the $e_i$, $m < i \leq n$ and of the $e_j$, $j$ even, $k \leq j \leq m$.

If $R$ has no elements of order 4, then $R \cong Z_2 \times \cdots \times Z_2$ is abelian. Suppose there is an element of order 4. We distinguish the cases $n$ even and $n$ odd.

**Case 1.** Suppose $n$ is even.

Then any element of $R$ of order 4 is conjugate to $w = (12)(34) \cdots (m-1 m)c_k c_{k+2} \cdots c_m c_{m+2} \cdots c_n$ with $k \leq m - 2$. Suppose for a moment that $m = n$. Then since $w \in W$ if and only if $\alpha - \alpha w \in \mathcal{L}$, the $\lambda_\alpha$ must satisfy relations corresponding to $e_i - e_j \equiv e_3 - e_4 \equiv \cdots \equiv e_{n-1} - e_n \equiv e_{n-1} + e_n$, $2(e_1 - e_2) \equiv 0$, and $2(e_i - e_j) \equiv 0$ mod $\mathcal{L}$ for $k \leq i < j \leq n$. Further, if $w \in R$ then $\mathcal{L} \cap \{e_i - e_j | k - 1 \leq i < j \leq n\} = 0$, and thus $\lambda$ is given by

\[
\begin{align*}
\text{sgn}_\theta & \text{sgn}_\theta & \text{sgn}_\theta & \text{sgn}_\theta & \text{sgn}_\theta & \text{sgn}_\theta & \text{sgn}_\theta \\
\end{align*}
\]

where $k = n - 2d$. 
Since \( w^2 = e_{k-1} c_k \cdots c_n \in R \), by Lemma 2, \( R \) contains the group \( \mathbb{Z}_{2^{d+1}} \) of all even sign changes on \( \{e_{k-1}, e_k, \ldots, e_n\} \). Then \((12)(34) \cdots (n-1 \, n) \in R \) and \( R \cong \langle (12)(34) \cdots (n-1 \, n) \rangle \times \langle c_{e_{n-1}}, c_{e_{n-2}}, \ldots, c_{e_{k-2}} \rangle \) is nonabelian.

If there are other sign changes in \( R \), we may assume they involve \( e_i, e_{i+1}, \ldots, e_{k-2}, \) where \( l \) is odd. Then the group \( R' \) of all sign changes in \( R \) consists all even sign changes on \( \{e_i, e_{i+1}, \ldots, e_n\} \) and each \( e_i - e_j, l \leq i < j \leq n \) corresponds to a character of order 2.

Now, if \( m < n, \ w = (12) \cdots (m-1 \, m)c_k c_{k+1} \cdots c_n \). \( c_{m+1} \cdots c_n \) acts on \( D_m = \{\pm e_i \pm e_j | 1 \leq i < j \leq m\} \subseteq \Phi \) as the above. Then \( e_i - e_j \equiv e_i - e_4 \equiv \cdots \equiv c_{m-1} - e_m \equiv e_{m-1} - e_m \mod \mathcal{L} \), and \( e_i - e_j \) corresponds to a character of order 2 for \( k-1 \leq i < j \leq m \) and for \( m + 1 \leq i < j \leq n \).

Thus \( e_{m-1} - e_m \equiv (e_{n-1} - e_n) + (e_{n-1} + e_n) \neq 0 \) and \( 2(e_{m} - e_{m+1}) \equiv e_{m-1} - e_m \mod \mathcal{L} \), and \( \lambda \) is given by

\[
\begin{array}{ccccccc}
\text{sgn}_0 & \text{sgn}_0 & \text{sgn}_0 & \text{sgn}_0 & \text{sgn}_0 & \text{sgn}_0 & \text{sgn}_0 \\
\text{sgn}_{o1} & \text{sgn}_{o2} & \text{sgn}_{o1} & \varPsi & \text{sgn}_{o1} & \text{sgn}_{o1} & \text{sgn}_{o1} \\
\end{array}
\]

with \( \varPsi^2 = \text{sgn}_s \).

Again, \( R \) contains \( sc = (12) \cdots (m-1 \, m)c_{m+1} \cdots c_n \) and we may assume by conjugation the \( R' \) consists of all even sign changes on \( \{e_i, \ldots, e_n\} \).

Then \( R \cong \langle sc \rangle \times R' \) is nonabelian, as before. Suppose there are other \( s'c' \) in \( R \). If \( s' = s \) then \( sc' \) is in the subgroup \( \langle sc \rangle \times R' \). If \( s' \neq s \) then \( R \cong \langle sc, s'c' \rangle \times R' \). We keep adding new elements of \( R \) until

**Lemma 4.** \( R = \{1, sc, s'c', \ldots\} \times R' \) with the permutations \( s^{(i)} \) distinct.

Further, the order of the first subgroup divides \( 2n \) by Lemma 3, and also \( R' \cong \mathbb{Z}_{2^{n-1}} \). Thus \( |R| \) divides \( n \cdot 2^n \).

Formally define a character corresponding to \( 2e_n \) to be \(- (e_{n-1} - e_n) + (e_{n-1} + e_n)\) and then use \( 2e_i = 2(e_i - e_n) + 2e_n \) to define a character corresponding to \( 2e_i \). If \( w = sc \in R, c \in \mathbb{Z}_{2^{n-1}} \) with \( s \neq 1 \), then \( e_i - we_i \) is a character of order 2 and \( w \mapsto e_i - we_i \) is an injective homomorphism on the first (nonnormal) factor of \( R \). Thus the order of this factor divides \( [f^*: (f^*)^2] \).

We have already seen that the number of factors of \( \mathbb{Z}_2 \) in \( R' \) is bounded by \( n - 1 \) and \( [f^*: (f^*)^2] - 1 \).
Finally, if \( n \) is even and \( R \) is abelian, we may write \( R = \{1, s, sc, s'e', \ldots \} \times R' \cong \mathbb{Z}_2 \times \cdots \times \mathbb{Z}_2 \) as in Lemma 4, with the \( s^{(i)} \) distinct. We show that the number of factors of \( \mathbb{Z}_2 \) is bounded by \( n - 1 \) and \( [t^* : (t^*)^2] - 1 \). If \( R = R' \), this is true. If \( R' = \{1\} \), then \(|R|\) divides \( 2n \) by Lemma 3 and divides \([t^* : (t^*)^2]\) by the above.

Suppose that both factors are nontrivial and that \( R \) is abelian. We may assume that \((12)(34)(n-1) n\) or \((12)(k-1)k\)\(\cdots c_{k+1} c_{m-3} c_{m-2} > z4 < zr^*1\).

Suppose that \((12) \cdots (k-1)k\)\(c_{k+1} \cdots c_n \) and \(c_1 \cdots c_{k-1} c_k \in R, k < n.\)

Then also \(c_{k-1} c_k \in R. \) Then if \( s'c' \in R, s' \neq 1, (12) \cdots (k-1)k, \) we may assume that \( c'(e_i) = e_i, i = k - 1, k. \) Then \( s'(k) \neq k - 1 \) by Lemma 3 and \( s'c' \) does not commute with \( c_{k-1} c_k, \) contradicting the assumption that \( R \) is abelian. Thus no other \( s'c' \) are in \( R. \) Further, if \( l < k - 1, \) then \( c_{k-l} c_{k-1} \in R, \) contradicting \( R \) abelian, and \( c_{k-1} c_k \) is the only sign change in \( R. \) Thus \(|R| = 4.\)

Suppose that \((12)(34) \cdots (n-1)n\) and \(c_1 \cdots c_{n-1} c_n \in R. \) Then if \(1 < i < n - 1, c_{n-2} c_{n-1} \in R, \) contradicting the assumption \( R \) is abelian. Thus \( i = 1 \) or \( n - 1. \) If \( i = 1, \) the \( R' = \{1, c_2, \ldots c_n\} \) and \(|R|\) divides \( 2n \) and \( 2[\tau^* : (\tau^*)^2]. \) If \( i = n - 1, \) then \(|R| = 4, \) as above.

We note that if \( \tau = R, \) then one can have \(|R| = 1, 2, \) or \( 4 \) in the case of \( D_n, n \) even.

**Case 2.** Suppose \( n \) is odd.

In this case any element of order 4 in \( R \) is conjugate to \( w = (12) \cdots (m-1)m. \) \( c_k c_{k+2} \cdots c_m c_{m+1} \cdots c_n, \) with \( k \leq m < n. \)

If \( m = n - 1 \) and \( w = (12) \cdots (n-2n-1) c_{n-1} c_n, \) then \( \lambda \) is given by

\[
\text{sgn}_\theta \quad \text{sgn}_\theta \quad \text{sgn}_\theta \quad \text{sgn}_\theta \quad \text{sgn}_\theta_d \quad \text{sgn}_\theta_{d-1} \quad \text{sgn}_\theta_1
\]

with \( \Psi^* = \text{sgn}_\theta. \)

Then \( w^2 = c_{k-1} c_k \cdots c_{n-1} \in R \) and thus \( R \) contains all even sign changes on \( \{e_{k-1}, e_k, \ldots, e_{n-1}\} \). Each \( e_i - e_j, k - 1 \leq i < j \leq n - 1 \) corresponds to a character of order 2 and also \( nc = (12) \cdots (n-2n-1) c_{n-1} c_n. \) We have \( R \cong \langle sc \rangle \times \langle c_{k-1} c_k, c_k c_{k+1}, \ldots, c_{n-3} c_{n-2} \rangle \cong \mathbb{Z}_4 \times \mathbb{Z}_2^{n-k-1}. \)

If \( m < n - 1 \) and \( w = (12) \cdots (m-1)m c_k c_{k+2} \cdots c_m c_{m+1} \cdots c_n \in R, \) then \( \lambda \) is given by
with $\Psi^2 = \text{sgn}_\theta$.

In this case, $w^2 = c_{k-1}c_k \cdots c_m \in R$ and $R$ contains all even sign changes on $\{e_{k-1}, \cdots, e_m\}$. Then $sc = (12) \cdots (m - 1 \ m)c_mc_{m+1} \cdots c_n \in R$ and each $e_i - e_j, \ k - 1 \leq i < j \leq m,$ and $m + 1 \leq i < j \leq n$, corresponds to a character of order 2. Also $2(e_m - e_{m+1}) \equiv e_m - e_{m+1} \equiv (e_{n-1} - e_n) + (e_{n-1} + e_n) \mod Z_2$.

$R \cong \langle sc \rangle \times \langle c_{k-1}c_k, c_2c_{k+1}, \cdots, c_{m-2}c_{m-1} \rangle = Z_4 \times Z_5^{n-k}$. Let $R''$ be the group of the even sign changes on $\{e_1, e_2, \cdots, e_{m-1}\}$ which occur in $R$. Then $R = \langle sc \rangle \times R''$ by

**Lemma 5.** If $s'c' \in R$, then $s' = 1$ or $s' = s = (12) \cdots (m - 1 \ m)$.

**Proof.** If $sc$ and $s'c'$ are in $R$, then $s's = ss'$ by Lemma 1, so that $s'$ permutes the odd number of fixed points $m + 1, \cdots, n$ of $s$. $s'$ must permute them faithfully by Lemma 3. But this contradicts Lemma 1, which implies that $s'$ must be a product of transpositions. Thus $R = \langle sc \rangle \times R'' \equiv Z_4 \times R''$.

Since $R'' \cong Z_4^{n-2} \cong Z_5^{n-3}$, the number of factors of $Z_5$ in $R''$ is bounded by $n - 3$. It is also bounded by $[f^\ast : (f^\ast)^2] - 2$, since the number of factors of $Z_5$ in $R' = \langle c_{m-1}c_m \rangle \times R''$ is bounded by $[f^\ast : (f^\ast)^3] - 1$.

Finally, suppose that $R$ is abelian and $n$ is odd. Then either there are no factors of $Z_5$ above, i.e., $k = m$, $R'' = \{1\}$ and $R \cong Z_4$, or $R$ is contained in the group $Z_5^{n-1}$ of even sign changes.

5. Type $E_6$.

**Theorem E_6.** $R \cong 1, Z_5, Z_3, Z_5 \times Z_3$ or $Z_3$. Further, $Z_5 \times Z_3$ occurs as a reducibility group if and only if $p = 3$ or 3 divides $q - 1$.

Arrange the simple roots in the traditional Dynkin diagram

\[ a_1 \rightarrow a_2 \rightarrow a_4 \rightarrow a_5 \rightarrow a_6 \]

\[ a_2 \rightarrow a_3 \]
The roots spanned by \( \{ \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_j \} \) form a subsystem of type \( D_5 \), giving an inclusion of Weyl groups \( W(D_5) < W(E_6) \). Comparing orders, \( 2^7 \cdot 3 \cdot 5 \) and \( 2^7 \cdot 3^* \cdot 5 \) respectively, we see that a 2-Sylow subgroup of \( W(D_5) \) is also a 2-Sylow subgroup of \( W(E_6) \). By conjugation, we may assume that a 2-Sylow subgroup of \( W_i \) is contained in \( W(D_5) \).

Let \( \alpha_3 = e_1 - e_5, \ldots, \alpha_5 = e_4 - e_5 \) and \( \alpha_2 = e_4 + e_5 \). Then by our \( D_5 \) results, potential candidates in \( R \cap W(D_5) \) are conjugate to \( c_c c_c c_i \), \( c_c (12) c_i c_i c_i \), or \( (12) (34) c_i c_i \). Adding the condition \( w \alpha_i = \alpha_i \), only \( c_c c_i c_i = w_{a_2} w_{a_2 + a_3 + a_4 + a_5} w_{a_2} w_{a_2} \) can be in an \( E_6 \) \( R \)-group.

If \( c_c c_i c_i \in R \), then \( \lambda \) is given by

\[
\begin{aligned}
\text{sgn}_\psi & \quad \text{sgn}_\chi & \quad \text{sgn}_\delta \\
\text{sgn}_\psi & \quad \text{sgn}_\chi & \quad \text{sgn}_\delta \\
\end{aligned}
\]

with \( \text{sgn}_\psi \neq \text{sgn}_\chi \). There can be no other elements of order 2 in \( R \) with \( c_c c_i c_i \); if there were another, by conjugation we could assume it is \( c_c c_i c_i \). But the product \( c_c c_i \) cannot be in an \( R \)-group.

Thus, if there is an element with order a power of 2 in \( R \), it has order 2 and is unique, hence is in the center of \( R \).

Note that the longest Weyl element \( w_0 \) and the character

\[
\begin{aligned}
\psi & \quad \chi & \quad \text{sgn}_\psi & \quad \chi^{-1} & \quad \psi^{-1} \\
\text{sgn}_\psi & \quad \chi & \quad \text{sgn}_\psi & \quad \chi^{-1} & \quad \psi^{-1} \\
\end{aligned}
\]

are conjugate to the above.

There is only one conjugacy class of elements of order 5 in \( W(E_6) \) and none of its elements can be in an \( R \)-group. Thus, \( R \) is the direct product of a 2-Sylow subgroup \( (1 \text{ or } Z_2) \) and a 3-Sylow subgroup. Examining conjugacy classes of elements of order 3 or 9, [5], any element in \( R \) with order a power of 3 is conjugate to one of \( w_{a_1} w_{a_2} w_{a_3} w_{a_5} \) or \( w_{a_1} w_{a_2} w_{a_3} w_{a_4} w_{a_5} w_{a_2} w_{a_2}^{12321} \), where \( 12321 \) represents the root \( \alpha_1 + 2\alpha_2 + 2\alpha_3 + 3\alpha_4 + 2\alpha_5 + \alpha_6 \).

For \( w_{a_1} w_{a_3} w_{a_4} w_{a_5} \in R \), \( \lambda \) is given by

\[
\begin{aligned}
\psi & \quad \psi & \quad \psi & \quad \psi^{-1} & \quad \psi^{-1} \\
\psi & \quad \psi & \quad \psi & \quad \psi^{-1} & \quad \psi^{-1} \\
\end{aligned}
\]

with \( \psi \) of order 3, giving \( R \cong Z_5 \). Further, if \( \lambda_{a_2} = \psi \) and \( \lambda_{a_4} \neq \psi^{\pm 1} \) have order 3, then \( R = \langle w_{a_1} w_{a_2} w_{a_3} w_{a_4} w_{a_5} w_{a_2} w_{a_2} w_{a_2} w_{a_2}^{12321} \rangle \cong Z_5 \times Z_3 \). If instead \( \lambda_{a_2} \neq \lambda_{a_4} \) have order 2, then \( R = \langle w_{a_1} w_{a_3} w_{a_4} w_{a_5}, w_0 \rangle \cong Z_9 \).
For $w_1 w_2 w_3 w_4 w_5 w_7 \in R$, $\lambda$ is given by
\[
\begin{array}{ccc}
\psi & & \chi \\
& \psi & \\
& & \psi \varphi^{-1}
\end{array}
\]
with each character having order 3, $\psi \neq \varphi$ and $\chi \in \langle \psi, \varphi \rangle$. Then
$R \cong Z_3$, or there is also an element of type $2A_2$ [5] in $R \cong Z_3 \times Z_3$, and we are in one of the above cases.

Note that if $G$ is a Chevalley group over $k = R$, then $R = 1$ and $\text{Ind}_G^R \lambda$ is irreducible.

6. Type $E_7$.

**Theorem $E_7$.** $R$ may be nonabelian. If so, $R \cong$ dihedral group $D$ of order 8, or $R \cong D \times Z_2$. $D \times Z_2$ can occur if and only if $p = 2$ or 4 divides $q - 1$.

If $R$ is abelian, then $R \cong Z_4^n$ with $0 \leq n \leq 4$, $Z_3$, $Z_4$ or $Z_6$. $Z_3$ and $Z_4$ occur if and only if $p = 2$. $Z_6$ occurs if and only if $[k^* : (k^*)^2] \geq 16$. $Z_4$ and $Z_6$ occur if and only if $p = 3$ or 3 divides $q - 1$.

Arrange the simple roots in the diagram
\[
\begin{array}{cccccc}
\alpha_1 & \alpha_2 & \alpha_4 & \alpha_3 & \alpha_5 & \alpha_6 \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
& & & & & \\
\alpha_2 & & & & & \\
\end{array}
\]
The roots $\{\alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6, \alpha_7\}$ span a subsystem of type $D_6$, giving an inclusion of Weyl groups $W(D_6) \subset W(E_7)$. Let $w_0 = -1$ be the longest Weyl element in $W(E_7)$. Comparing orders, $2^6 \cdot 3^3 \cdot 5$ and $2^6 \cdot 3^4 \cdot 5 \cdot 7$, $\langle w_0 \rangle \times x$ a 2-Sylow subgroup of $W(D_6)$ will be a 2-Sylow subgroup of $W(E_7)$. We first classify 2-Sylow subgroups of $R$-groups.

Let $\alpha_i = e_i - e_5$, $\cdots$, $\alpha_5 = e_6 - e_5$, and $\alpha_6 = e_6 + e_5$. Using our $W(D_6)$ notation and grouping by $W(E_7)$-conjugacy classes, elements in $R$ with order a power of 2 are conjugate to:

- $3A_1$: $(12)(34)(56)c_c c_5$, $w_0 c_c c_5$
- $4A_1$: $c_c c_5 c_6$, $w_0(12)(34)(56)c_c c_6$
- $5A_1$: $(12)c_c c_5 c_6$, $w_0(34)(56)$, $w_0 c_c c_5$
- $6A_1$: $c_c c_c c_5 c_6$, $w_0(56)$
- $7A_1$: $w_0 = -1$
- $D_1(\alpha_1) + 2A_1$: $(12)(34)c_c c_5 c_6$, $w_0(12)(34)(56)c_c c_6$
- $2A_3 + A_1$: $w_0(12)(34)c_c c_5$. 
Suppose there is an element of order 4 in $R$. If it has type $D_4(\alpha_1) + 2A_1$, we may assume it is $(12)(34)c_c c_0 c_6$ and $\lambda$ is given by $s_{\varphi} s_{\psi} s_{\vartheta} s_{\chi}^{-2} s_{\gamma}$ with $\psi^2 = s_{\vartheta} \neq s_{\varphi}$. Then $R \cong \langle(13)(24)(56)c_4 \rangle \times \langle(12)(34)c_c c_c c_6 \rangle \cong$ dihedral group $D_4$.

If $\lambda_{a_1}$ is "generic", then $R \cong D$ is nonabelian with order 8. If $R$ is larger, a consideration of other possible elements shows that we may assume, by conjugation, that $R$ contains one of $w_c c_c c_c c_5$, $w_c c_c c_c c_6$, or $w_c c_c c_c c_0$. Each of these three cases occurs, giving $R \cong D \times Z_2$ nonabelian of order 16.

In the first case, $\lambda_{a_1}^2 = s_{\varphi} s_{\psi}$, which can occur if, and only if $[k: (k^*)^4] \geq 16$, i.e., $p = 2$ or 4 divides $q - 1$.

In the second case, $\lambda_{a_1} \neq s_{\varphi} s_{\psi}$, $s_{\varphi} s_{\psi}$ has order 2, which can occur if, and only if $p = 2$.

In the third case, $\lambda_{a_1}^2 = s_{\varphi} s_{\psi}$ and $\lambda_{a_1}^{-1} \neq s_{\varphi} s_{\psi}$, $s_{\varphi} s_{\psi}$ has order 2, which occurs if, and only if $p = 2$.

We may now suppose that $R$ contains no elements of type $D_4(a_1) + 2A_1$.

Suppose that $R$ contains $w_0(12)(34)c_c c_0$. Then $\lambda$ is given by $\chi = s_{\varphi} s_{\psi} s_{\vartheta} s_{\chi}^{-1} s_{\gamma}$ with $\psi^2 = s_{\varphi} \neq s_{\vartheta}$. $\chi$ of order 4 and $\chi^2 = s_{\varphi} s_{\psi}$, then we are in one of the above cases with $(12)(34)c_c c_c c_0 \in R$. Otherwise, $\chi^2 \notin \langle s_{\varphi} s_{\psi} \rangle$, so $p = 2$, and then $R \cong Z_4$.

If $R$ contains no elements of order 4, then a 2-Sylow subgroup of $R$ is a product of copies of $Z_2$. An explicit list shows that $Z_2$ occurs for any $k$, even the reals $R$; that $Z_4$ occurs for any non-Archimedean $k$ (we will need 2 characters of order 2); that $Z_4$ occurs if, and only if $p = 2$; and $Z_4$ occurs if, and only if $[k: (k^*)^4] \geq 16$.

An easy calculation shows that $R$ can contain no elements of order 5 or 7. Of elements of order a power of 3, only conjugates of $w_{a_1} w_{a_2} w_{a_3} w_{a_4} w_{a_5} w_{a_6} w_{a_7} w_{a_8}(3A_2)$ can be in an $R$-group. If this element is in $R$, then $\lambda$ is given by $\psi^2 = s_{\varphi} \neq s_{\varphi}$.
with $\psi \neq \mathbb{Z}^{+1}$ of order 3. There are no other elements of order 3 in $R$ with this one, besides its inverse. Since we may specify only one character of order 2, there can be at most one element of order 2 in this $R$. Thus, $R \cong \mathbb{Z}_n$. This does occur, with $R$ generated by an element of type $A_5 + A_5$.

7. Type $E_8$.

**Theorem $E_8$.** A nonabelian $R$-group will occur if and only if $[k^*: (k^*)^2] \geq 16$. All nonabelian $R$ are isomorphic to $(12)(34)(56)(78)$ or $(13)(24)(57)(68)$ or $(15)(26)(37)(48)$ or $C_2 \times C_2 \times C_2 \times C_2$.

If $R$ is abelian, then $R \cong \mathbb{Z}^n$ with $0 \leq n \leq 4$, $\mathbb{Z}_4 \times \mathbb{Z}_2$, $\mathbb{Z}_5$, $\mathbb{Z}_5 \times \mathbb{Z}_2$, or $\mathbb{Z}_6$.

$\mathbb{Z}^n_2$ occurs if and only if $[k^*: (k^*)^2] \geq 2^{n+1}$, $0 \leq n \leq 4$. $\mathbb{Z}_4$ occurs if and only if $p = 2$ or 4 divides $q - 1$. $\mathbb{Z}_4 \times \mathbb{Z}_2$ occurs if and only if $p = 2$. $\mathbb{Z}_5$ occurs if and only if $[k^*: (k^*)^2] \geq 9$ and $\mathbb{Z}_5 \times \mathbb{Z}_2$ occurs if and only if $[k^*: (k^*)^2] \geq 27$. $\mathbb{Z}_6$ occurs if and only if $[k^*: (k^*)^2] \geq 25$, i.e., $p = 5$ or 5 divides $q - 1$.

Arrange the simple roots in the diagram

```
\begin{center}
\begin{tikzpicture}
\node (a1) at (0,0) {$\alpha_1$};
\node (a2) at (1,0) {$\alpha_2$};
\node (a3) at (2,0) {$\alpha_3$};
\node (a4) at (3,0) {$\alpha_4$};
\node (a5) at (4,0) {$\alpha_5$};
\node (a6) at (5,0) {$\alpha_6$};
\node (a7) at (6,0) {$\alpha_7$};
\node (a8) at (7,0) {$\alpha_8$};
\draw (a1) -- (a2);
\draw (a2) -- (a3);
\draw (a3) -- (a4);
\draw (a4) -- (a5);
\draw (a5) -- (a6);
\draw (a6) -- (a7);
\draw (a7) -- (a8);
\end{tikzpicture}
\end{center}
```

Letting $\beta = -(245321)$, $\Phi$ contains a subsystem of type $D_8$ spanned by

```
\begin{center}
\begin{tikzpicture}
\node (a1) at (0,0) {$\alpha_1$};
\node (a2) at (1,0) {$\alpha_2$};
\node (a3) at (2,0) {$\alpha_3$};
\node (a4) at (3,0) {$\alpha_4$};
\node (a5) at (4,0) {$\alpha_5$};
\node (a6) at (5,0) {$\alpha_6$};
\node (a7) at (6,0) {$\alpha_7$};
\node (a8) at (7,0) {$\alpha_8$};
\draw (a1) -- (a2);
\draw (a2) -- (a3);
\draw (a3) -- (a4);
\draw (a4) -- (a5);

\draw (a6) -- (a7);
\draw (a7) -- (a8);
\end{tikzpicture}
\end{center}
```

giving an inclusion of Weyl groups $W(D_8) < W(E_8)$. Comparing orders, $2^4 \cdot 3^2 \cdot 5 \cdot 7$ and $2^4 \cdot 3^2 \cdot 5^2 \cdot 7$, we see that a 2-Sylow subgroup of $W(D_8)$ is also a 2-Sylow subgroup of $W(E_8)$. Thus we may assume that a 2-Sylow subgroup of $R$ is contained in $W(D_8)$; we first classify these groups.

In this realization, the orderings determined by the positive roots are not compatible between the $D_n$ and $E_n$ root systems. However, easy modifications of the proofs show that Lemmas 1 and 3 of §$D_n$, hold. Adding the condition $w\alpha_2 = \alpha_2$ in $E_8$, we see that possible
elements in $W(D_s) \cap R$, grouped by $W(E_n)$-conjugacy classes, are conjugate to

$4A_1: C_2C_2C_2C_2, (12) (34) (56) (78)C_2$,

$6A_1: C_3C_3C_3C_3C_3C_3, (12) (34) C_3C_3C_3$,

$7A_1: (12) C_4C_4C_4C_4C_4C_4$,

$8A_1: w_0 = -1$,

$2D_4(a_i): (12) (34) (56) (78)C_2C_2C_2C_2$,

$D_4(a_i) + 3A_1: (12) (34) (56)C_3C_3C_3C_3C_3$, or

$D_4(a_i) + 4A_1: (12) (34) C_5C_5C_5C_5C_5$.

Suppose there is an element of order 4 in $R$. If there is one of type $2D_4(a_i)$, we may assume it is $(12) (34) (56) (78)C_2C_2C_2C_2$. Then $\lambda$ is given by

\[
\begin{align*}
\text{sgn}_\theta \\
\text{sgn}_\epsilon \\
\text{sgn}_\phi \\
\text{sgn}_\theta \\
\text{sgn}_\epsilon \\
\text{sgn}_\phi \\
\text{sgn}_\theta
\end{align*}
\]

with $|\langle \text{sgn}_\theta, \text{sgn}_\epsilon, \text{sgn}_\phi, \text{sgn}_\phi \rangle| = 16$. This can occur if and only if $[k^*: (k^*)^2] \geq 16$, and in this case, $\lambda' = \phi$.

Then

$R = W_4$

$= \langle (12) (34) (56) (78)C_2C_2C_2C_2, (13) (24) (57) (68)C_2C_2C_2C_2, (15) (26) (37) (48)C_2C_2C_2C_2, C_2C_2C_2C_2 \rangle$

is nonabelian of order 128 and has 65 conjugacy classes. $R \text{ odm } \langle w_0 \rangle$ is abelian of order 64.

Now suppose that $R$ does not contain an element of type $2D_4(a_i)$, but does contain $(12) (34) (56)C_4C_4C_4C_4$ of type $D_4(a_i) + 3A_1$. Then $\lambda$ is given by

\[
\begin{align*}
\text{sgn}_\theta \\
\text{sgn}_\phi \\
\lambda_2 \\
\text{sgn}_\theta \\
\text{sgn}_\phi \\
\lambda_7 \\
\text{sgn}_\theta
\end{align*}
\]

with $\lambda_2 = \text{sgn}_\theta$ and $\lambda_7 = \text{sgn}_\theta \text{sgn}_\phi$. This can occur if and only if $p = 2$ or 4 divides $q - 1$. An examination of other possible elements in $R$ with this one shows that $R \cong Z_4$ if $\lambda_2$ and $\lambda_7$ satisfy no additional conditions. If $\lambda_7$ has order 2, $\lambda_2 \notin \langle \text{sgn}_\theta, \text{sgn}_\phi \rangle$, then $C_4C_4C_4C_4 \in R \cong Z_4 \times Z_4$. If instead $\lambda_7 = \text{sgn}_\theta$, $\lambda_2\lambda_7^{-1}$ has order 2, $\lambda_2\lambda_7^{-1} \notin \langle \text{sgn}_\theta, \text{sgn}_\phi \rangle$, then $(12) (35) (46) (78)C_2C_2 \in R \cong Z_4 \times Z_4$. These two cases occur if and only if $p = 2$.

Next, assume that $R$ does not contain elements of types $2D_4(a_i)$
or $D_i(a_i) + 3A_i$, but does contain $(12)(34)C_2C_4C_5C_7C_8$ of type $D_i(a_i) + 4A_i$. Then \( \lambda \) is given by

\[
\begin{array}{cccccccc}
\text{sgn}_\phi & \text{sgn}_\varepsilon & \text{sgn}_\pi & \lambda_4 & \text{sgn}_\theta & \text{sgn}_\varepsilon & \text{sgn}_\pi & \lambda_5
\end{array}
\]

with $\lambda_4 \equiv \text{sgn}_\theta$ and $\lambda_5 \equiv \text{sgn}_\theta \text{sgn}_\varepsilon$, and $R \cong \mathbb{Z}_3$. This case occurs if and only if \([k^*: (k^*)^3] \geq 16\).

Now assume that $R$ contains no elements of order 4. An explicit list shows that a 2-Sylow subgroup of $R$ is then $\mathbb{Z}_2^r$ with $0 \leq n \leq 4$. Further, $\mathbb{Z}_2^r$ occurs if and only if \([k^*: (k^*)^3] \geq 2^{n+1}, 0 \leq n \leq 4\).

Using the fact that no elements of order 6 can be in an $E_6$ $R$-group, it is easy to see that the other $R$-groups which occur are isomorphic to $\mathbb{Z}_3$, $\mathbb{Z}_3 \times \mathbb{Z}_3$ or $\mathbb{Z}_3$.

$R \cong \mathbb{Z}_3$ may be generated by an element of type $3A_2$ or $4A_2$.

To construct $R \cong \mathbb{Z}_3 \times \mathbb{Z}_3$, note that $\Phi$ contains a subsystem of type $A_3$ spanned by \( \{\alpha_9, \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6, \alpha_7, \alpha_8\} \), where $\alpha_9 = \frac{1304121}{3}$. Letting $\alpha_9 = e_1 - e_2$, $\alpha_9 = e_2 - e_3$, $\ldots$, $\alpha_9 = e_8 - e_9$, $R = \langle (123)(456)(789), (147)(258)(369) \rangle$ occurs for the character $\psi, \chi, \varphi$ of order 3 and $|\langle \psi, \chi, \varphi \rangle| = 27$.

$\mathbb{Z}_3$ will occur as an $R$-group, generated by an element of type $2A_4$, if and only if \([k^*: (k^*)^3] \geq 25\).

8. Type $F_4$. $\Phi^\prime = \{\pm 2e_8, \pm e_i \pm e_j, \pm e_i \pm e_j \pm e_k \pm e_l | 1 \leq i < j < k < l \leq 4\}$ is of type $F_4$. A base for $\Phi^\prime$ is given by $\alpha_1 = e_2 - e_3$, $\alpha_2 = e_3 - e_4$, $\alpha_3 = 2e_4$, and $\alpha_4 = e_1 - e_2 - e_3 - e_4$.

$\Phi^\prime = \{\pm e_i \pm e_j | 1 \leq i < j \leq 4\}$ is a sub-root system of type $D_4$ with Weyl group $W(\Phi^\prime) \cong S_4 \times Z_2^3$ acting as permutations and even sign changes on the $e_i$. The Weyl group for $\Phi$ and $\Phi^\prime$ of type $\Phi^\prime$ is $S_4 \ltimes W(\Phi^\prime) \cong S_4 \times (S_4 \times Z_2^3)$, where $S_4$ acts as permutations of $e_1 - e_2$, $e_3 - e_4$, and $e_3 + e_4$.

If $w_\alpha \alpha = \alpha - n(\alpha, \beta) \beta$, the Cartan matrix $[n(\alpha, \beta)]$ of $\Phi^\prime$ is

\[
\begin{bmatrix}
2 & -1 & 0 & 0 \\
-1 & 2 & -1 & 0 \\
0 & -2 & 2 & -1 \\
0 & 0 & -1 & 2
\end{bmatrix}
\]
The reader is referred to Bourbaki [2] for more details.

**Theorem** $F_4$. $R \cong 1, Z_2$ or $Z_3$. $Z_3$ can occur as an $R$-group if and only if $p = 3$ or $3$ divides $q - 1$.

**Lemma 1.** Suppose $w = sd \in R$ with $s \in S_3$ and $d \in S_3 \ltimes Z_2^3$. Then $s$ has order 1 or 3.

**Proof.** $s \in S_3$ has order 1, 2, or 3, so that $w = sd, w^2,$ or $w^3$ is in the normal subgroup $S_3 \ltimes Z_2^3$. Further, this element must be able to give reducibility for $D_4$, so that $w, w^2,$ or $w^3$ is conjugate to one of $1, c_c c_2 c_4, (12)c_c c_4, (12)(34),$ or $(12)(34)c_c c_4$.

But of these, only $1, c_c c_2 c_4,$ and $(12)c_c c_4$ can be in an $R$-group for $\Phi$ of type $F_4$. Thus $w, w^2,$ or $w^3$ is conjugate to one of $1, c_c c_2 c_4,$ or $(12)c_c c_4$.

Suppose that $s$ has order 2, so that $w^2 = 1, c_c c_2 c_4,$ or $(12)c_c c_4$. We may assume that $s = w a_2 = c_4 = (e_2 - e_4, e_2 + e_4)$. Then if $d = \sigma c$ with $\sigma \in S_3$ and $c \in Z_2$, $w^2 = c_4(\sigma c c_2 c_4)(\sigma c c_2 c_4)\sigma c_4$. Since $(12) \neq c_4$ for any $c$, we must have $\sigma^2 = 1$ and thus $c_4(\sigma c c_2 c_4) = w^2 = 1$ or $c_c c_2 c_4$.

By conjugation we may assume that $\sigma = 1, (12), (34),$ or $(12)(34)$. But then $w^2 \neq c_c c_2 c_4$ for any $c \in Z_2$, so we have $w^2 = 1$. But $\sigma = (12)(34)$ will not give $w^2 = 1$ for any $c$.

Thus $\sigma = 1$ and $w = c_c$, $c \in Z_2$, or $\sigma = (12)$ and $c = 1$, $c_c c_2 c_4$, or $c_c c_2 c_4$, or $c = (34)$ and $c$ is conjugate to $c_c c_2$ or $c_c c_4$. Then $w = \sigma c_c$ is conjugate to one of $c_c, c_c c_2 c_4,$ or $(12)c_c c_4$. But none of these can be in an $R$-group for $\Phi$ of type $F_4$. Thus $s$ can not have order 2.

If $s = 1$, then $w = sd \in W(\Phi')$.

**Lemma 2.** Suppose $R \subseteq W(\Phi')$. Then $R \cong Z_2$.

**Proof.** Any element of $R \cap W(\Phi')$ is conjugate to one of $1, c_c c_2 c_4$, or $(12)c_c c_4$. $c_c c_2 c_4$ can not be in an $R$-group with any conjugate of $(12)c_c c_4$, so if $c_c c_2 c_4 \in R$, then $R = \langle c_c c_2 c_4 \rangle \cong Z_2$.

Suppose $(12)c_c c_4 \in R$. Then $\lambda$ is given by

where $\text{sgn}_\sigma \neq \text{sgn}_{\sigma'}$ are of order 2. If there is another nontrivial element of $R$, we may assume by conjugation that it is $c_c (34)$. We then would need $\alpha$ to correspond to a character $\mathcal{F}$ with $\mathcal{F}^a = \text{sgn}_\alpha \text{sgn}_{\sigma'}$. But then $2\alpha_i + 2\alpha_2 + \alpha_3 + \alpha_4 \in \mathcal{L} \cap \Phi'$ and $c_c (34)$ sends this to a negative root, so it is not in an $R$-group with $(12)c_c c_4$. Thus $R = \langle (12)c_c c_4 \rangle \cong Z_2$.

Now suppose there exists an element $w = sd \in R$ with $s \neq 1,$
Consider the elements \( w_\alpha w_\beta, w_\alpha^2, (w_\alpha w_\beta w_\alpha)^3 = w_{3\alpha + \beta} w_{3\alpha + \beta} \), and \((w_\alpha w_\beta w_\alpha^2 w_\alpha)^3 \) of order 3. The first 3 elements can not give reducibility. The last gives reducibility if \( \lambda \) is given by

\[
\lambda_1 \lambda_2 \lambda_3 \lambda_2^2 \lambda_3
\]

where \( \lambda_2 \neq \lambda_2^{-1} \) are characters of order 3.

The above 4 elements are pairwise nonconjugate. Further, none is conjugate to the inverse of another. Since the order of the Weyl group \( W \) is \( 3^3 \cdot 2^3 \), we see that any 3-Sylow subgroup of \( W \) consists of 1 and conjugates of the above four elements and their inverses. Thus there is a unique subgroup of order 3 in any 3-Sylow subgroup which can be part of an \( R \)-group.

Thus any element of order 3 in \( R \) is conjugate to \((w_\alpha w_\beta w_\alpha^2 w_\alpha)^3 \) or its inverse. In this case all \( \alpha \) correspond to characters of order 3, and thus \( R \) can not contain an element of order 2, which would have to be conjugate to \( c_\alpha c_\beta c_\alpha \) or \((12)c_\alpha c_\beta \). Thus an element of order 6 can not occur, and we have shown that \( R \cong \{1\}, \mathbb{Z}_2 \), or \( \mathbb{Z}_3 \).

Explicitly, if \( R \neq \{1\} \), then \( R \) is conjugate to one of \( \langle c_\alpha c_\beta c_\alpha \rangle \cong \mathbb{Z}_2 \) with all \( \lambda_\alpha \) of order 2, or \( \langle (12)c_\alpha \rangle \cong \mathbb{Z}_2 \) with \( \lambda \) given by

\[
\lambda_1 \lambda_2 \lambda_3 \lambda_2^2 \lambda_3
\]

with \( \text{sgn}_\alpha \neq \text{sgn}_\beta \), or \( \langle (w_\alpha w_\beta w_\alpha^2 w_\alpha)^3 \rangle \cong \mathbb{Z}_3 \) with \( \lambda \) given by

\[
\lambda_1 \lambda_2 \lambda_3 \lambda_2^2 \lambda_3
\]

where \( \lambda_2 \neq \lambda_2^{-1} \) are of order 3.

We note that if \( \mathfrak{g} = \mathbb{R} \), then \( R \cong \{1\} \), and thus \( \text{Ind}_G^\mathfrak{g} \lambda \) is irreducible if \( G \) is a Chevalley group of type \( F_4 \) over the reals.

9. Type \( G_2 \). Let \( \{\alpha, \beta\} \) be a base for \( \Phi^r \) with Cartan matrix

\[
\begin{bmatrix}
2 & -1 \\
-3 & 2
\end{bmatrix}
\]

The positive roots in \( \Phi^r \) are \( \alpha, \beta, \alpha + \beta, 2\alpha + \beta, 3\alpha + \beta \), and \( 3\alpha + 2\beta \). The Weyl group \( W \) is a dihedral group of order 12.

**Theorem G_2.** \( R \cong \{1\} \) or \( R = \langle w_0 \rangle \cong \mathbb{Z}_2 \), where \( w_0 \) is the Weyl group element of maximal length.

One checks that the element \( w_0 \) of maximal length is the only Weyl group element giving reducibility. \( R = \langle w_0 \rangle \) if and only if \( \alpha \) and \( \beta \) correspond to distinct characters of order 2.

If \( \mathfrak{g} \) is nonArchimedean, \([\mathfrak{g}^* : (\mathfrak{g}^*)^2] \geq 4\), and such characters exist. If \( \mathfrak{g} = \mathbb{R} \), then \( R \cong \{1\} \) and \( \text{Ind}_G^\mathfrak{g} \lambda \) will be irreducible.
CHAPTER III
ON THE DECOMPOSITION OF Ind^g λ

1. Multiplicities of the irreducible components. If R is abelian, then there are |R| irreducible components, each occurring with multiplicity 1.

Write \(C[R] = M_{n_1}(C) \oplus \cdots \oplus M_{n_k}(C)\). Then \(m_1, m_2, \ldots, m_k\) are the multiplicities of the \(k\) inequivalent irreducible components of \(\text{Ind}^g_\lambda\). \(k\) is equal to the dimension of the center of \(C[R]\), which equals the number of conjugacy classes in \(R\). Further, the \(m_i\) are the degrees of the irreducible representations of the group \(R\). We note that if \(R\) has a normal abelian subgroup \(R'\), then the degrees \(m_i\) divide the index of \(R'\) in \(R\), by Ito's Theorem.

Suppose \(R\) is non-abelian. Then \(G\) is of type \(D_n, E_7\) or \(E_8\).

Suppose \(G\) is type \(D_n\), with \(n\) odd. Then \(R \cong Z_4 \times R''\) contains a normal abelian subgroup \(R'\) of index 2, so \(m_i = 1\) or 2. If \(p\) is odd, then \(R \cong Z_4 \times (Z_2 \times Z_2)\) has 16 conjugacy classes in \(R\). Thus we have the decomposition \(64 = 2 \cdot 2^3 + 16 \cdot 1^4\), and \(\text{Ind}^g_\lambda\) decomposes into 2 irreducible components of multiplicity 2, and 8 irreducible components of multiplicity 1.

If \(p = 2\), there may be more factors of \(Z_2\) in \(R\). We note that \(R \cong Z_4 \times (Z_2 \times Z_2)\) has 28 conjugacy classes, giving the decomposition \(256 = 56 \cdot 2^4 + 32 \cdot 1^6\).

Suppose \(G\) is type \(D_n\) with \(n\) even. Then any non-abelian \(R\) is isomorphic to \((Z_2 \times \cdots \times Z_2) \times R'\). If \(p\) is odd, \(R'\) is the group of even sign changes on \(\{e_n, e_{n-1}, e_{n-2}, e_{n-3}\}\) and the first factor is \(\langle(12)(34)\cdots(n-1 \ n)\rangle\) or \(\langle(12)(34)\cdots(n-1 \ n), (13)(24)\cdots(n-2 \ n)\rangle\).

In the first case, \(m_i = 1\) or 2, \(|R| = 16\) and there are 10 conjugacy classes in \(R\). \(16 = 2 \cdot 2^2 + 8 \cdot 1^4\) gives the decomposition into 2 irreducible components of multiplicity 2, and 8 of multiplicity 1.

In the second case, \(|R| = 32\) and there are 17 conjugacy classes. The two possible decompositions are \(32 = 4^2 + 16 \cdot 1^4 = 5 \cdot 2^2 + 12 \cdot 1^4\). But since \(R/\langle c_n c_{n-1} c_{n-2} c_{n-3}\rangle\) is abelian, there are at least 16 one-dimensional representations of \(R\), so the decomposition must be \(32 = 4^2 + 16 \cdot 1^4\). Thus \(\text{Ind}^g_\lambda\) decomposes into 16 irreducible components of multiplicity 1, and 1 component of multiplicity 4.

If \(G\) is type \(E_7\), the nonabelian \(R\)-groups are the dihedral group \(D\) of order 8 and \(D \times Z_2\). \(R \cong D\) gives the decomposition \(8 = 1 \cdot 2^2 + 4 \cdot 1^2\) and \(R \cong D \times Z_2\) gives the decomposition \(16 = 2 \cdot 2^2 + 8 \cdot 1^4\).

If \(G\) is type \(E_8\), the nonabelian \(R\)-group has order 128, 65 conjugacy classes, and \(R/\langle w_0 \rangle\) is abelian of order 64. This gives the decomposition \(128 = 1 \cdot 8^2 + 64 \cdot 1^4\), so \(\text{Ind}^g_\lambda\) decomposes into 1 irre-
ducible components with multiplicity 8, and 64 irreducible components each with multiplicity 1.

2. Some analysis on $L^\iota(V)$. In this section we realize the operators $a(w, \lambda)$ on $L^\iota(V)$ via a Fourier transform, where $V$ is the unipotent radical of the Borel subgroup opposed to $B$. We find a class of functions in $L^\iota(V)$ on which $\hat{a}(w, \lambda)$ acts as multiplication by a bounded function $M(w, \lambda)$. This class has nonzero intersection with each invariant subspace for groups of type $A_n$ and $B_n$.

Write $\varphi_\delta(y)$ for $\varphi, (J_\iota | U_\delta) in U_\delta$ and let $n_\alpha = \varphi_\alpha \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right)$ for $\alpha$ simple, where $\varphi_\alpha : SL(2) \rightarrow G$ is the canonical homomorphism corresponding to the root $\delta$.

Write $V = \prod_{s \subset O} U_s$ in some fixed order. Since each $U_s$ is isomorphic to $\mathfrak{t}$, this gives a topological isomorphism of $V$ with the product of $|\Phi^-|$ copies of $\mathfrak{t}$. We then define a Fourier transform on $L^\iota(V)$ by

$$\hat{f}(\prod_{s \subset O} \varphi_s(c_s)) = \int f(\prod_{s \subset O} \varphi_s(y_s)) \lambda(\sum_{s \subset O} c_sy_s) \prod dy_s,$$

where $\lambda$ is a fixed additive character of $\mathfrak{t}$ with conductor the ring of integers.

Fix a simple root $\alpha > 0$. Then

$$A(w_\alpha, \lambda)f(g) = A(n_\alpha, \lambda)f(g)$$

$$= \int_{U_\alpha} f(g \varphi_\alpha \left( \begin{array}{cc} 1 & u \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right)) du$$

$$= \int f(g \varphi_\alpha \left( \begin{array}{cc} 1 & 0 \\ 1/u & 1 \end{array} \right) \varphi_\alpha \left( \begin{array}{cc} -u & 1 \\ 0 & -1/u \end{array} \right)) du$$

$$= \int f(g \varphi_\alpha \left( \begin{array}{cc} 1 & 0 \\ 1/u & 1 \end{array} \right)) \lambda^{-1}(-u) \frac{du}{|u|}$$

$$= \int f(g \varphi_\alpha \left( \begin{array}{cc} 1 & 0 \\ u & 1 \end{array} \right)) \lambda(u) \frac{du}{|u|}.$$
\[ \mathcal{A}(w_\alpha, \lambda) f(\lambda) = \int \int \prod_{Q_\beta \neq 0} f_\delta(y_\beta) \overline{\chi}(\sum c_\beta y_\beta) \prod_{Q_\beta \neq 0} f_\delta(y_\beta + Q_\delta(y_\beta)u) \overline{\chi}(\sum c_\delta y_\delta) \times \lambda_a(-u) \overline{\chi}(-c_\alpha u) \frac{du}{|u|} \prod dy_\delta \prod dy_\beta = 0 \]

unless \( y_\beta \in S_\beta \) for all \( \beta \) with \( Q_\beta = 0 \). Fix \( y_\beta \in S_\beta \) and consider

\[ \int \int f_\delta(y_\beta - Q_\delta(y_\beta)u) \overline{\chi}(\sum c_\delta y_\delta) \lambda_a(u) \overline{\chi}(c_\alpha u) \frac{du}{|u|} \prod dy_\delta . \]

This will be zero unless \( y_\beta - Q_\delta(y_\beta)u \in S_\delta \) for all \( \delta \). Thus we need only integrate \( u \) over the intersection \( \bigcap_\delta (1/Q_\delta(y_\beta))(y_\beta - S_\delta) = (1/Q_\delta(y_\beta))(y_\beta - S_\delta), \) for some \( \delta_0 \), and integrate \( y_\delta \) over the coset \( \frac{Q_\delta(y_\delta)}{Q_\delta(y_\delta)} y_\delta + S_\delta \).

Write

\[ \int_{\delta_0} = \int_{\delta_0} + \sum \int_{\delta} \]

where the sum is over shells \( \mathcal{S} \) consisting of nonzero cosets of \( S_{\delta_0} \).

The above integral becomes

\[ \int \int_{\delta_0} \int_{\delta \neq \delta_0} \prod f_\delta(y_\beta - Q_\delta(y_\beta)u) \overline{\chi}(\sum c_\delta y_\delta) \lambda_a(u) \overline{\chi}(c_\alpha u) \frac{du}{|u|} \prod dy_\delta + \sum \int \int_{\mathcal{S}} \prod f_\delta(y_\beta - Q_\delta(y_\beta)u) \overline{\chi}(\sum c_\delta y_\delta) \lambda_a(u) \overline{\chi}(c_\alpha u) \frac{du}{|u|} \prod dy_\delta . \]

In each term in the sum, we are integrating \( \lambda_a(u) \overline{\chi}(c_\alpha u) \) over
a shell \((1/Q_\delta(y_\beta))S^\perp\) which is disjoint from \(S_\delta \cap \delta Q(y_\beta)\). Thus we are integrating \(\lambda_a(u)\tilde{\chi}(u)\) over a shell disjoint from \((1/Q_\delta(y_\beta))\cap \delta S_\delta\), which gives zero, by the definition of \(S_\delta\) and properties of the gamma function \([29, 35]\).

We are left with only the first term. Note that

\[
\int_{(1/Q_\delta(y_\beta))S_\delta} \lambda_a(u)\tilde{\chi}(e^{-a}u) \frac{du}{|u|} = \lambda_a^{-1}(e^{-a}) \cdot \Gamma(\lambda_a).
\]

We get that

\[
\hat{A}(w_\lambda) \hat{f}(\hat{g}) = \int_{\Pi_i v_i S_i^\perp} \int_{S_\delta} \int_{S_\delta} \prod \delta \phi(y_\delta) \prod f_\alpha(y_\beta) \prod f_\beta(y_\delta - Q_\delta(y_\delta)u) 
\times \tilde{\chi}(\sum c_\delta y_\delta) \lambda_a(u)\tilde{\chi}(e^{-a}u) \frac{du}{|u|} \prod d y_\delta \prod d y_\beta.
\]

This is zero unless \(y_\beta \in S_\delta\), \(c_\delta \in \supp \delta f_\alpha\) and \(u \in 1/c_\delta \times (p^{-h}\setminus p^{h+1})\) for \(\lambda_a\) ramified of degree \(h\), or \(u \in 1/c_\delta \times \mathcal{O}\) for \(\lambda_a\) unramified. But then \(Q_\delta(y_\delta)u \in S_\delta\) and \(f(y_\delta - Q_\delta(y_\delta)u) = f(y_\delta)\). Thus for such \(\hat{f}\),

\[
\hat{A}(w_\lambda) \hat{f}(\hat{g}) = \lambda_a^{-1}(e^{-a}) \Gamma(\lambda_a) \prod \delta \hat{f}_\delta(c_\delta) = \lambda_a^{-1}(e^{-a}) \Gamma(\lambda_a) \hat{f}(\hat{g})
\]

Thus \(\hat{A}(w_\lambda) = (1/\Gamma(\lambda_a)) A(w_\lambda, \lambda)\) acts on such \(\hat{f}\) as multiplication by \(M(w_\lambda, \lambda) = \lambda_a^{-1}(e^{-a})\). Then if \(w = w_{a_1}w_{a_2} \cdots w_{a_l}\), \(\hat{A}(w, \lambda)\) acts on such \(\hat{f}\) as multiplication by the function \(M(w, \lambda) = M(w_{a_1}, w_{a_2} \cdots w_{a_l}) \cdots M(w_{a_l})\), by the cocycle condition.

We note that \(w \mapsto M(w, \lambda)\) is a homomorphism, and further, that we may evaluate \(M(w, \lambda)\) at \(V_{-\alpha}\) for any simple root \(\alpha\) to obtain a homomorphism from \(W_\lambda\) into \((\mathfrak{t}^*)^\perp\). If this homomorphism is injective on \(R\) for some \(\alpha\), then the linear independence of distinct characters of \(\mathfrak{t}^*\) implies that the operators \(\{a(w, \lambda) \mid w \in R\}\) are linearly independent. Further, we may write \(|R|\) nonzero projections giving \(\hat{f}\) as above in each invariant subspace.

The homomorphism is injective on \(R\) for groups of type \(A_n\) and \(B_n\), but is not necessarily injective for groups of type \(C_n\) and \(D_n\). We may show the linear independence of the operators \(\{a(w, \lambda) \mid w \in R\}\) for these groups as follows.

As in \([37]\), let \(f_\lambda = f_{\lambda, \lambda}\) be the function in \(H_\lambda\) whose restriction to \(K\) is supported on the Iwahori \(I\) and is constant on \(I \cap V\). Then \(a(w, \lambda) f_\lambda(w') = 0\) if and only if \(ww' \neq 1\), provided that \(l(w') \geq l(w)\), that \(\Gamma_{\lambda}(\lambda)\) and \(\Gamma_{\lambda}^{-}(\lambda)\) are defined, and the characters \(\lambda_\beta\) are ramified for all \(\beta \in R(\lambda)\). (The proof is by induction on the length of \(w\). Write \(w = w_0 \bar{w}\) with \(l(\bar{w}) = l(w) - 1\) and use the fact that \(\lambda_{-1}^{-}\) is ramified.)

To show that \(\{a(w, \lambda) \mid w \in R\}\) are linearly independent, it is enough to find a \(w_0 \in R\) such that \(a(w, \lambda) f_\lambda(w_0) = 0\) if and only if
If all \( \lambda_\alpha \) are ramified, use the above. Otherwise, since we know what groups \( R \) can occur, we may check that \( w_0 \in R \) consisting of as many sign changes as possible will work for groups of type \( C_n \) and \( D_n \).

Mathematical papers intended for publication in the Pacific Journal of Mathematics should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Please do not use built up fractions in the text of the manuscript. However, you may use them in the displayed equations. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Please propose a heading for the odd numbered pages of less than 35 characters. Manuscripts, in triplicate, may be sent to any one of the editors. Please classify according to the scheme of Math. Reviews, Index to Vol. 39. Supply name and address of author to whom proofs should be sent. All other communications should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints to each author are provided free for each article, only if page charges have been substantially paid. Additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966, Regular subscription rate: $114.00 a year (6 Vol., 12 issues). Special rate: $57.00 a year to individual members of supporting institutions.

Subscriptions, orders for numbers issued in the last three calendar years, and changes of address should be sent to Pacific Journal of Mathematics, P.O. Box 969, Carmel Valley, CA 93924, U.S.A. Old back numbers obtainable from Kraus Periodicals Co., Route 100, Millwood, NY 10546.
