ZERO-INDUCING FUNCTIONS ON FINITE ABELIAN GROUPS

GEORGE LUCIUS O’BRIEN
Let $G$ be a finite abelian group and let $f: G \to G$ be any function. Let $r_x: G \to G$ be the function $r_x(y) = x + y$, $x \in G$. A study is made of conditions on $f$ such that the semi-group of functions generated by $f$ and all $r_x$ under composition contains the zero function. If $G$ is cyclic, it is necessary and sufficient that $f$ not be one-to-one. In general some necessary conditions are given and a partial converse is given for these conditions, which involve the behaviour of $f$ on subgroups and cosets of $G$.

1. Introduction. Let $G$ be any finite set and let $\mathcal{F}$ be a collection of functions from $G$ into $G$. Let $\mathcal{A}$ be the semigroup of functions $A: G \to G$ which is generated by $\mathcal{F}$; that is, $A \in \mathcal{A}$ iff $A$ can be expressed as a composition $A = h_1 h_2 \cdots h_k$ where each $h_i \in \mathcal{F}$. The question we examine is the following: does $\mathcal{A}$ contain any constant functions? Let $V = V(\mathcal{F}) = \min\{\lvert A(G)\rvert : A \in \mathcal{A}\}$ where $\lvert \cdot \rvert$ denotes cardinality. Obviously, $\mathcal{A}$ contains a constant function if and only if $V = 1$. A more general problem is to evaluate $V$.

We mainly consider a very special case of the situation described above. Except in §2, we assume throughout that $G$ is a finite abelian group (with additive notation and identity 0) and that $\mathcal{F}$ consists of all the functions $r_x: G \to G$ given by $r_x(y) = x + y$ (translation by $x$) and one other function $f: G \to G$. We do not assume $f$ is a homomorphism. In this situation, we write $V(f)$ for $V(\mathcal{F})$. If $\mathcal{A}$ contains any constant function, it clearly contains them all. We say $f$ is zero-inducing if $\mathcal{A}$ contains the zero function.

In §2, we give two simple lemmas for the general (non-group) case. In §3, we apply these to the group case. An obvious necessary condition for $f$ to be zero-inducing is that $f$ not be one-to-one. Corollary 1 states that this is sufficient if $\lvert G \rvert$ is prime. If $\lvert G \rvert$ is not prime, it is not sufficient, as is easily seen from some of the examples in §3. That section also contains a lower bound for $V$ which involves the behaviour of $f$ on subgroups of $G$ and their cosets. In §4, the adequacy of this lower bound is discussed.

The problem of whether $f$ is zero-inducing arose as a result of an attempt to solve the "road-coloring conjecture" of Adler, Goodwyn, and Weiss [1]. This graph-theoretic conjecture, which reduces in some case to the present problem (see [2]), arose in turn from their study of ergodic theory. Our zero-inducing question is also related
to some questions in computer science which deal with resetting the state of a computer to zero before beginning a new program. The problem has independent interest, whatever the original motivation. The road-colouring conjecture only involves the case when $G$ is cyclic, but the results we present here apply equally well to other finite abelian groups. Some of the theorems are a little more complicated in the general case.

It is clear that $V(f) = V(r_x f)$ for any $x \in G$. Taking $x = -f(0)$, we observe in particular that $r_x f(0) = f(0) - f(0) = 0$. We may therefore assume without loss of generality that $f(0) = 0$. Similarly we note that the set

\[(1) \quad \mathcal{A} \equiv \{ A \in \mathcal{A} : |A(G)| = V \text{ and } A(0) = 0\} \]

is non-empty.

We use the following notation. If $X, Y \subseteq G$, then $X + Y = \{x + y : x \in X, y \in Y\}$. If $g \in G$, we write $g + Y$ for $\{g\} + Y$. We let $X \oplus Y$ denote $X + Y$ only if the sums $x + y$ for $x \in X$ and $y \in Y$ are distinct. If $H$ and $K$ are groups, we let $H \oplus K$ be the group $\{(h, k) : h \in H, k \in K\}$ with componentwise addition. Finally, $Z_n$ denotes the cyclic group $\{0, 1, \cdots, n-1\}$ with addition performed modulo $n$.

2. The general case. In this section, we obtain two simple equivalent formulations of $V(\mathcal{A})$ under the general conditions described in the first paragraph of Section 1. For $k \geq 1$, a $k$-collection is a non-empty set $\mathcal{C}$ of subsets of $G$ such that each $Y \in \mathcal{C}$ has exactly $k$ elements and such that for any $\{y_1, \cdots, y_k\} \in \mathcal{C}$ and any $h \in \mathcal{A}$, the set $\{h(y_1), \cdots, h(y_k)\} \in \mathcal{C}$. In particular, for $Y \in \mathcal{C}$, the restriction of $h$ to $Y$ is one-to-one. The set of singleton sets of elements of $G$ is evidently a $1$-collection.

**Lemma 1.** $V(\mathcal{A})$ is the largest value of $k$ for which there exists a $k$-collection.

*Proof.* Suppose $\mathcal{C}$ is a $k$-collection and $\{y_i, \cdots, y_k\} \in \mathcal{C}$. By induction on the number of composing factors making up $A$ (the non-uniqueness of this number does not matter), the set $\{A(y_i), \cdots, A(y_k)\} \in \mathcal{C}$ for any $A \in \mathcal{A}$. Thus $|A(G)| \geq |A(\{y_i, \cdots, y_k\})| = k$ so that

\[(2) \quad V(\mathcal{A}) \geq k. \]

Now suppose $A \in \mathcal{A}_0$ and let $A(G) = \{y_1, y_2, \cdots, y_r\}$. Define $Y_B = \{B(y_i), \cdots, B(y_r)\}$ for $B \in \mathcal{A}$ and let $\mathcal{C} = \{Y_B : B \in \mathcal{A}\}$. If $B(y_i) = B(y_j)$ for any $B$ and any $i, j$, then $|BA(G)| = |B(\{y_1, \cdots, y_r\})| < V$ unless $i = j$. Thus each $Y_B \in \mathcal{C}$ has $V$ elements. It follows that $\mathcal{C}$ is a $V$-collection. This and (2) together prove Lemma 1.
It is all too clear that Lemma 1 is not much direct help in finding $V$. The next lemma shows that the $V$-collection produced in the above proof has associated with it some further structure which is useful for finding $V$, especially, as we will see in §3, in the case of groups.

A $k$-partition $(\mathcal{P}, \mathcal{C})$ of $G$ is a partition $\mathcal{P} = \{P_1, \ldots, P_k\}$ of the set $G$ together with a $k$-collection $\mathcal{C}$ such that for each $\{y_i, \ldots, y_k\} \in \mathcal{C}$, there is a permutation $\pi$ on $\{1, 2, \ldots, k\}$ such that $y_{\pi(i)} \in P_i$, $i = 1, 2, \ldots, k$.

**Lemma 2.** $V(\mathcal{F})$ is the largest value of $k$ for which there exists a $k$-partition.

**Proof.** If $G$ has a $k$-partition, $V(\mathcal{F}) \geq k$ by Lemma 1. Let $A \in \mathcal{A}$ with $A(G) = \{y_1, \ldots, y_r\}$ and let $\mathcal{P} = \{A^{-1}(y_1), \ldots, A^{-1}(y_r)\}$. By Lemma 1,

$$\mathcal{C} = \{\{B(y_1), \ldots, B(y_r)\} : B \in \mathcal{A}\}$$

is a $V$-collection. If for any $B \in \mathcal{A}$, $B(y_i)$ and $B(y_j)$ are both in the same set $A^{-1}(y_k)$, then $|ABA(G)| = |AB(\{y_1, \ldots, y_r\})| < V$ unless $i = j$. Thus $(\mathcal{P}, \mathcal{C})$ is a $V$-partition of $G$.

3. The case when $G$ is a group. We assume henceforth that $G$ is a finite abelian group and that $\mathcal{F}$ contains $r_x$ for all $x \in G$ and exactly one other function $f$. It is equivalent, of course, for $\mathcal{F}$ to contain $f$ and $r_x$ for all $x$ in a set which generates $G$. We begin by establishing a stock of examples. These examples kindled most of the results of this paper.

**Example 1.** Let $G = \mathbb{Z}_6$ and let $f(0) = 0$, $f(1) = 4$, $f(2) = 1$, $f(3) = 4$, $f(4) = 2$ and $f(5) = 3$. Then $V(f) = 1$ since $A = r_2f r_3f f r_1f f$ is the zero function.

**Example 2.** Let $G = \mathbb{Z}_2 \oplus \mathbb{Z}_2$. Let $f(0, 0) = f(0, 1) = (0, 0)$, $f(1, 1) = (1, 1)$ and $f(1, 0) = (1, 0)$. Since $f$ is not one-to-one, $V < 4$. It is easily seen (and it follows from Theorem 2) that $V = 2$.

**Example 3.** Again take $\mathbb{Z}_2 \oplus \mathbb{Z}_2$ but now take $f(0, 0) = f(0, 1) = (0, 0)$ and $f(1, 0) = f(1, 1) = (1, 1)$. Once more, $V = 2$.

**Example 4.** Let $G = \mathbb{Z}_8$ and let $f(g) = f(g + 2) = g$ for $g = 0, 1, 4, 5$. Then $V = 4$.

**Example 5.** Let $G = \mathbb{Z}_{12}$ and let $f(0) = f(2) = f(4) = 0$, $f(6) =$
\[ f(8) = f(10) = 1, \quad f(1) = f(5) = f(9) = 6, \quad \text{and} \quad f(3) = f(7) = f(11) = 7. \]
Then \( V = 4. \)

**Example 6.** Let \( G = \mathbb{Z}_3 \oplus \mathbb{Z}_3 \oplus \mathbb{Z}_3 \) and let \( f(x, y, 0) = (y, y, 0) \) and \( f(x, y, 1) = (x, 2x, 0) \) for all \( x, y \in \mathbb{Z}_3. \) Then \( V = 3. \)

**Example 7.** Let \( G = \mathbb{Z}_n \) for some \( n \) and let \( f \) be any homomorphism. It is easily seen that in this case, \( V = \min \{|f^m(G)| : m = 1, 2, \ldots\}. \) Also, \( V = 1 \) if and only if every prime factor of \( n \) divides \( f(1). \)

An inspection of Example 1 and other examples leads to the following condition for \( V = 1. \)

**Theorem 1.** Let \( X_0 = \{0\} \) and, for \( k > 0, \) let
\[ X_k = \{x \in G : x \in X_{k-1} \text{ or } f(x + y) - f(y) \in X_{k-1} \text{ for some } y \in G\}. \]
Then \( V = 1 \) if and only if
\[ G = \bigcup_{k=1}^{\infty} X_k. \]

**Proof.** Since \( \{X_k\} \) is a nondecreasing sequence of sets, it is equivalent to show \( V = 1 \) if and only if \( G = X_k \) for some \( k. \) Suppose first that \( G = X_k. \) Let \( A \in \mathcal{X} \) be such that \( A(0) = 0 \) and \( A(x) \neq 0 \) for some \( x \in G. \) Then \( x \in X_j \) but \( x \notin X_{j-1} \) for some \( j > 0. \) Thus, there exists \( y \in G \) such that
\[ z = r_{-f(y)} f r_y (x) = f(x + y) - f(y) \in X_{j-1}. \]
Also,
\[ r_{-f(y)} f r_y (0) = f(y) - f(y) = 0. \]
Applying the same argument to \( z \) and continuing the process, we may construct \( B \in \mathcal{X} \) such that \( B(x) = B(0) = 0. \) Thus \( V \leq |BA(G)| < |A(G)|. \) By the arbitrary nature of \( A, \) it follows that \( V = 1. \)

Now suppose \( V = 1. \) Then \( A(G) = \{0\} \) for some \( A \in \mathcal{X}. \) Clearly, \( A \) may be written in the form
\[ A = r_{x_n} f r_{x_{n-1}} f \cdots f r_{x_1} f r_{x_0} \]
for some \( n \geq 1 \) and \( x_0, x_1, \ldots, x_n \in G. \) Let \( v_i = x_0 \) and for \( i = 2, 3, \ldots, n, \) let \( v_i = x_{i-1} + f(v_{i-1}). \) Let \( g_i = r_{-f(v_i)} f r_{v_i}, i = 1, 2, \ldots, n. \) Then \( g_i(0) = 0 \) for each \( i \) and
\[ g_n g_{n-1} \cdots g_1 = r_{-f(v_n)} f r_{v_n - f(v_{n-1})} f \cdots f r_{v_2 - f(v_1)} f r_{v_1} \]
\[ = r_{-f(v_n)} f r_{v_n - f(v_{n-1})} f \cdots f r_{v_2 - f(v_1)} f r_{v_1} f r_{v_0} \]
\[ = r_{-x_n - f(v_n)} A = A. \]
The last step follows from the fact that both sides map 0 into 0. We will show by induction that

\[(g_ng_{n-1} \cdots g_{n-i})^{-1}(0) \subseteq X_{i+1}.\]

This is true for \(i = -1\) (where the composition of no functions is taken to be the identity function). Assume (3) holds for \(i - 1\) and let \(x \in (g_ng_{n-1} \cdots g_{n-i})^{-1}(0)\). Then \(f(x + v_{n-i}) - f(v_{n-i}) = g_{n-i}(x) \in (g_ng_{n-1} \cdots g_{n-i+1})^{-1}(0) \subseteq X_i\). Therefore \(x \in X_{i+1}\), so (3) holds for all \(i\). Taking \(i = n - 1\), (3) gives \(G = A^{-1}(0) \subseteq X_n\), which proves Theorem 1.

The sequence \(\{X_k\}\) of sets in the above theorem is eventually constant. Moreover, if \(X_k = X_{k-1}\), then all subsequent terms are identical, so it is clear when a maximal term has been reached. The main shortcoming of Theorem 1 is that it does not avoid an iterative procedure. In an attempt to avoid an iterative method, we apply the notions of §2 to the case of groups. We first demonstrate that the number of partitions which are eligible to be \(k\)-partitions is limited.

**Lemma 3.** Let \((\mathcal{P}, \mathcal{E})\) be a \(k\)-partition of \(G\), let \(\mathcal{P} = \{P_1, \ldots, P_k\}\) and let \(Y \in \mathcal{E}\). Then

\[G = P_i \oplus Y\]

for \(i = 1, 2, \ldots, k\).

**Proof.** Let \(u, v \in P_i\), \(x, y \in Y\) and suppose \(x + u = y + v\). Setting \(w = x - v = y - u\), we obtain \(r_w(x) = x - (x - v) = v\) and \(r_w(y) = u\). By the definition of \(k\)-partition, it follows that \(x = y\) and hence that \(u = v\). The \(|P_i|/k\) sums \(x + u\) where \(x \in Y\) and \(u \in P_i\) are distinct. Thus \(|G| \geq |P_i|/k\). Also, \(|G| = \sum_{i=1}^k |P_i|\) so that in fact \(|P_i| = |G|/k^{-1}\) for each \(i\). Thus \(G = P_i \oplus Y\) for each \(i\).

Combining Lemmas 2 and 3 immediately gives

**Corollary 1.** \(V\) divides \(|G|\). In particular, if \(G = Z_p\) for \(p\) prime, \(V = 1\) if \(f\) is not one-to-one.

To find \(V\), one need only examine partitions \(\mathcal{P} = \{P_1, \ldots, P_k\}\) such that each \(P_i\) has \(|G|/k^{-1}\) elements and such that there exists a set \(Y\) for which \(G = Y \oplus P_i\) for each \(i\). An obvious candidate for a \(k\)-partition is the collection of cosets of a subgroup of \(G\). This leads us to the next theorem, which gives a lower bound for \(V\), and thereby gives a necessary condition for \(V = 1\). We need the following definitions.

A subgroup \(H\) of \(G\) is called \(f\)-regular if for each \(a \in G\), \(f(a + H) \subseteq \)
$f(a) + H$, i.e., if $f$ maps cosets into cosets. Since $f(0) = 0$ by assumption, this implies in particular that $f(H) \subseteq H$. A pair $(L, K)$ of subgroups of $G$ is noncombative of order $\alpha = \alpha(L, K)$ if $L$ and $K$ are $f$-regular, and there exist subgroups $H_1, \ldots, H_m$ of index $\alpha$ in $K$ and elements $x_1, \ldots, x_x$ of $K$ such that $x_j - x_k \in \bigcup_{i=1}^m H_i$ for distinct $j$ and $k$, $\bigcap_{i=1}^m H_i = L$, and if $x, y \in G$ are such that $x - y \in K$ but $x - y \notin \bigcup_{i=1}^m H_i$, then $f(x) - f(y) \in \bigcup_{i=1}^m H_i$.

It is clear that the above condition are unaffected if $x_\lambda$ is replaced by $X_j - x_\lambda$ for each $j$, so we may assume that $x_1 = 0$. Suppose $(L, K)$ is noncombinative of order $\alpha$ and suppose the quantity $m$ equals one. This is necessarily the case if $K$ (or $G$) is cyclic, since the subgroups $H_1, H_2, \ldots, H_m$ are all of the same order. Then $H_1 = L$, $|K: L| = \alpha$ and one of $x_1, \ldots, x_x$ is in each coset of $L$. Conversely, if $L$ and $K$ are $f$-regular subgroups with $L \subseteq K$ and if $x - y \in K$ but $x - y \notin L$ imply $f(x) - f(y) \in L$, then $(L, K)$ is non-combinative of order $\alpha$ (with $m = 1$).

**Theorem 2.** Suppose $G$ has subgroups $L_1 \subseteq K_1 \subseteq L_2 \subseteq K_2 \subseteq \cdots \subseteq L_r \subseteq K_r$ where each pair $(L_j, K_j)$ is noncombinative of order $\alpha_j$. Then

$$(4) \quad V(f) \geq \prod_{j=1}^r \alpha_j .$$

**Proof.** Let $\beta_k = \prod_{j=1}^k \alpha_j$ and $\gamma_k = \prod_{j=k}^r \alpha_j$ for $k = 1, \ldots, r$ and let $\beta_0 = \gamma_{r+1} = 1$. We show $V \geq \beta_r$ by constructing a $\beta_r$-collection and by applying Lemma 1. For $j = 1, 2, \ldots, r$, let $H_{j,i}, i = 1, 2, \ldots, m_j$, and $x_{j,i}, i = 1, 2, \ldots, \alpha_j$ be the subgroups and elements of $K_j$ with the properties indicated in the definition of non-combinative. As noted above, we may assume $x_{j,i} = 0$ for $j = 1, 2, \ldots, r$.

Let $\mathcal{C}$ be the collection of all subsets of $G$ with $\beta_r$ elements such that for $Y \in \mathcal{C}$

(i) for $j = 1, 2, \ldots, r$, exactly $\gamma_{j+1}$ of the cosets of $K_j$ each contain exactly $\beta_j$ elements of $Y$.

(ii) for $j = 1, 2, \ldots, r$ and $i = 1, 2, \ldots, m_j$, exactly $\gamma_j$ of the cosets of $H_{j,i}$ each contain exactly $\beta_{j-1}$ elements of $Y$.

Note that $\mathcal{C}$ is nonempty since the set $\{x_{i_1} + \cdots + x_{r_i}; 1 \leq i_j \leq \alpha_j, 1 \leq j \leq r\}$ is in $\mathcal{C}$. If $Y \in \mathcal{C}$, it follows from (i) and (ii) that

(iii) the distinct cosets of $K_j$ which intersect $Y$ are contained in distinct cosets of $H_{j+1,i}$ for $j = 1, 2, \ldots, r - 1$ and $i = 1, 2, \ldots, m_j$.

Let $Y \in \mathcal{C}$. It is obvious that for any $x \in G$ the set $r_x(Y) = \{x + y; y \in Y\}$ is also in $\mathcal{C}$. We will show that $f(Y)$ is also in $\mathcal{C}$. First, suppose there exist $y, z \in Y$ such that $y - z \in \bigcup_{j=1}^m H_{j,i}$ but $f(y) + H_{j,i} = f(z) + H_{j,i}$ for some $j$ and $i$. Since $(L_j, K_j)$ is non-combinative, $y + K_j \neq z + K_j$. By (iii), $y - z \in \bigcup_{j=1}^m H_{j+1,i}$ while, on
the other hand, it is clear that \( f(y) + H_{j+1,i} = f(z) + H_{j+1,i} \). Proceeding by induction, we conclude that \( y + K_r \neq z + K_r \), which contradicts (i) for \( j = r \). Thus

\[
(5) \quad y - z \notin \cup H_{j,i} \implies f(y) - f(z) \notin \cup H_{j,i}
\]

for all \( y, z \in Y \) and all \( i, j \). Now let \( y, z \in Y \) be such that \( y + K_j \neq z + K_j \) for some \( j \). By (i), \( j < r \). Then \( y + H_{j+1,i} \neq z + H_{j+1,i} \) by (iii). By (5), \( f(y) + H_{j+1,i} \neq f(z) + H_{j+1,i} \). Since \( K_j \subseteq H_{j+1,i} \), we conclude that

\[
(6) \quad y + K_j \neq z + K_j \implies f(y) + K_j \neq f(z) + K_j
\]

for \( y, z \in Y \) and any \( j \). It follows from (5) with \( j = 1 \) that \( f \) is one-to-one on \( Y \) and then from (5) and (6) that \( f(Y) \in \mathcal{C} \). We have proved \( \mathcal{C} \) is a \( \beta_r \)-collection. By Lemma 1, \( V \supseteq \beta_r \), which proves Theorem 2.

**Remarks.** It is easy to construct a \( \beta_r \)-partition \((\mathcal{P}, \mathcal{C})\) under the hypotheses of Theorem 2, by taking \( \mathcal{C} \) to be as in the proof and \( \mathcal{P} \) to be constructed from unions of cosets of the subgroups.

Let \( \delta = \delta(f) \) denote the maximum value that can be attained by a product of the type given in (4). Since the pair \((G, G)\) is always noncombinative of order 1, we set \( \delta = 1 \) if there are no noncombinative pairs \((L, K)\) of subgroups with \( L \subset K \). Finding \( \delta(f) \) for a given \( f \) is generally not too difficult since attention may be restricted to \( f \)-regular subgroups.

4. **How good is the bound \( V \geq \delta \)?** To answer this, we first look at the examples discussed earlier.

In Example 1, it is obvious that \( \delta = V = 1 \). In Example 2, the value \( \delta = 2 = V \) is obtained by taking \( r = 1, K_1 = G, \) and \( L_1 = \{(0, 0), (0, 1)\} \). In Example 3, the value \( \delta = 2 = V \) can be obtained in two ways. Either take \( r = 1, K_1 = G \) and \( L_1 = \{(0, 0), (0, 1)\} \) or take \( r = 1, K_1 = \{(0, 0), (1, 1)\} \) and \( L_1 = \{(0, 0)\} \). In Example 4, the value \( \delta = 4 \) is achieved by taking \( r = 2, L_2 = \{0\}, K_1 = \{0, 4\}, L_2 = \{0, 2, 4, 6\} \) and \( K_2 = G \). The value \( \delta = 4 \) cannot be attained if only one noncombinative pair is used. In Example 5, \( \delta = 1 \neq V \). In Example 6, \( \delta = 3 = V \) is attained by taking \( r = 1, K_1 = \{x, y, x \in G: x = 0\} \) and \( L_1 = \{(0, 0, 0)\} \). The pair \((L, K)\) is noncombinative with \( H_{11} = \{0, 0, 0\}, (1, 0, 0), (2, 0, 0)\), \( H_{12} = \{(0, 0, 0), (0, 1, 0), (0, 2, 0)\} \), \( x_1 = \{0, 0, 0\}, x_2 = \{(1, 1, 0)\}, \) and \( x_3 = \{2, 0, 0\} \). Finally, in Example 7, let \( a = f(1) \) and let \( m \) be sufficiently large that \( V = |f^m(G)| \). The value \( \delta = V \) is attained by taking \( r = 1, L_1 = \{0\}, \) and \( K_1 = \{0, a, 2a, \ldots, (V-1)a^m\} \).

Example 5 shows that it is not always true that \( \delta = V \), and in
fact it is possible that $V > 1$ when $\delta = 1$. Consider the simple upper bound for $V$, namely

$$V(f) \leq |f(G)|.$$ 

Note that in Examples 3, 4 and 5, $V$ attains this upper bound. We were unable to construct any example for which

$$\delta < V < |f(G)|.$$ 

(Furthermore, in every example we have studied for which $V < |f(G)|$, the value of $\delta$ is attainable by using one noncombinative pair of order $\delta$ in Theorem 2.) On the other hand, we have not been able to prove that no such examples exist. The difficulty in proving such a result is underlined by the length of the proof of the following very special result.

**Theorem 3.** Suppose $V \leq 3$. Then $G$ has a non-combinative pair of subgroups of order $\alpha = V$.

**Proof.** The case $V = 1$ is obvious. Assume $V = 2$ or 3. Define

$$Y = \{ y \in G : \exists A \in \mathcal{A} \text{ such that } y \in A(G) \}$$

and let $K$ be the subgroup generated by $Y$. Define

$$\mathcal{H} = \{ H : H = A^{-1}(0) \cap K \text{ for some } A \in \mathcal{A}_0 \}$$

and let $L = \bigcap_{H \in \mathcal{H}} H$. We will show that $(L, K)$ is noncombinative of order $V$. We break the proof into several lemmas.

**Lemma 4.** Let $B \in \mathcal{H}$ and $z \in G$. Then $B(z + K) \subseteq B(z) + K$. In particular (taking $B = f$), $K$ is $f$-regular.

**Proof.** Let $u = B(z)$ and observe that

$$r_u Br_z(0) = r_u B(z) = 0.$$ 

For any $y \in Y$,

$$B(z + y) - u = r_u Br_z(y) \in Y \subseteq K.$$ 

Thus $B(z + y) \in u + K$. Now, every element of $K$ is a sum of elements of $Y$. The lemma follows by induction on the number of terms in the sum.

The next step is to show each $H \in \mathcal{H}$ is a subgroup of $K$. Fix $A \in \mathcal{A}_0$ for now and let $H = A^{-1}(0) \cap K$. Denote the elements of $A(G)$ by \{ $x_0 = 0, x_1, x_2, \cdots, x_{r-1}$ \}. First, let $f_K$ be the restriction of $f$ to $K$
and let \( \mathcal{A}_K \) be the semi-group of functions on \( K \) generated by \( f_\kappa \) and \( r_x, x \in K \). The collection \( \mathcal{B} = \{ A^{-1}(x_i) \cap K: x_i \in A(G) \} \) is a partition of \( K \). Let \( \mathcal{C} = \{ (B(x_0), \ldots, B(x_{V-1})): B \in \mathcal{A}_K \} \). It is clear that \( (\mathcal{B}, \mathcal{C}) \) is a \( V \)-partition of \( K \).

By Lemma 3,

\[
|H| = |A^{-1}(0) \cap K| = |K| V^{-1}.
\]

**Lemma 5.** Let \( a \in G \) and let \( B \in \mathcal{A}_K \). Let \( B(G) = \{ u_0, u_1, \ldots, u_{V-1} \} \). For \( i, j = 0, 1, \ldots, V-1 \), exactly one of the expressions

\[
a + u_j - u_k, k = 0, 1, \ldots, V-1
\]

and one of the expressions

\[
a + u_k - u_j, k = 0, 1, \ldots, V-1
\]

is in each set \( A^{-1}(x_i) \cap (a + K) \).

**Proof.** Obviously, each element of (9) is in \( a + K \). Suppose \( a + u_j - u_k \) and \( a + u_j - u_i \) are both in \( A^{-1}(x_i) \). Then

\[
AR_{a+u_j-u_k}B(G) = AR_{a+u_j-u_k}(u_i) = x_i.
\]

By the definition of \( V \),

\[
|AR_{a+u_j-u_k-u_i}B(G)| = V
\]

so (11) implies that \( k = i \). This proves the first statement. The second is proved similarly.

We now assume \( V = 3 \). A similar proof will show the result in the case \( V = 2 \). Lemma 5 has particularly strong implications for these two values of \( V \). Denote the elements of \( Y \) by \( y_0, y_1, y_2, \ldots, y_i \) and let

\[
I_i = \{ j: y_j \in A^{-1}(x_i) \}, \quad i = 0, 1, 2.
\]

In particular, \( I_0 = \{0\} \). No \( I_i \) is empty since for any \( B \in \mathcal{A}_K, B(G) \) has 3 elements, one in each \( A^{-1}(x_i) \).

**Lemma 6.** Let \( b \in A^{-1}(x_{i_0}), B \in \mathcal{A}_K, B(G) = \{ u_0, u_1, u_2 \} \). Let \( j_1, j_2 \) and \( j_3 \) be distinct elements of \( \{0, 1, 2\} \). Suppose \( b + (u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_0}) \) and \( b + 2(u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_0}) \). Then \( i_0, i_1 \) and \( i_2 \) are distinct and \( b + r(u_{j_1} - u_{j_2}) \in A^{-1}(x_{i'}) \) where \( i' = i_0, i_1 \) or \( i_2 \) according as \( r \equiv 0, 1 \) or 2 (mod 3).

**Proof.** Let \( a = b + (u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_0}) \). Since \( a = a + (u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_1}) \), it follows from Lemma 5 that \( a + (u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_2}) \) and
\[ b = a + (u_{j_2} - u_{j_1}) \in A^{-1}(x_{i_1}). \] Thus \( i_0 \neq i_1 \) and \( i_1 \neq i_2 \). Suppose \( i_0 = i_2 \).

Then \( a + (u_{j_2} - u_{j_1}) \in A^{-1}(x_{i_0}) \) and \( a + (u_{j_1} - u_{j_2}) \in A^{-1}(x_{i_0}) \). By Lemma 5, we must have \( a = a + (u_{j_2} - u_{j_1}) \in A^{-1}(x_{i_0}) \), which is a contradiction. Therefore \( i_0, i_1 \) and \( i_2 \) are distinct. The rest of the lemma follows easily by induction.

**Lemma 7.** Let \( z \in K \). Then \( z \in A^{-1}(x_k) \) iff \( z \) can be expressed in the form

\[ z = \sum_{j=1}^{i} c_j y_j \]

where the \( c_j \)'s are non-negative integers and

\[ \sum_{j \in I_1} c_j + 2 \sum_{j \in I_2} c_j \equiv k \pmod{3}. \]

Also, \( H \) is a subgroup of \( K \) and \([K:H] = 3\).

**Proof.** Since any \( z \in K \) can be written in the form (13) for some non-negative \( c_j \)'s it is enough to prove the sufficiency. We do this by induction on \( m = \sum_{j=1}^{i} c_j \). The statement is true for \( m = 0 \). If \( m = 1 \), then one \( c_j = 1 \) and all others are zero. Then \( z = y_j \) for some \( j \) and the result is obvious for \( j \in I_1 \) or \( j \in I_2 \). Now assume the result holds whenever \( m \leq m_0 \), where \( m_0 \geq 1 \). Let \( c_1, c_2, \ldots, c_i \) be such that \( \sum c_j = m_0 \) and let \( a = \sum c_j y_j \). Let \( j_0 \in I_1 \cup I_2 \). It suffices to show the result holds for \( a + y_{j_0} \). Let \( D(k) = A^{-1}(x_k) \), \( k = 0, 1, \ldots, V - 1 \).

By the inductive hypothesis

\[ a \in D(k) \]

where \( k \) is given by (14). Suppose initially that \( c_{j_0} > 0 \). Then

\[ a - y_{j_0} \in D(k - i_0) \]

where \( i_0 \) is such that \( j_0 \in I_{i_0} \). [Here and throughout, the arguments for \( D \) are calculated modulo 3.] It follows from Lemma 6 that

\[ a + y_{j_0} \in D(k + i_0) \]

as required. Now suppose \( c_{j_0} = 0 \). Since \( m_0 \geq 1 \), there is some \( j \) such that \( c_{j_1} > 0 \). Then

\[ a - y_{j_1} \in D(k - i_1) \]

where \( i_1 \) is such that \( j_1 \in I_{i_1} \). We then have

\[ a - y_{j_1} + y_{j_0} \in D(k - i_1 + i_0) \]

and, by the previous case,
(20) \[ a + y_{i_1} \in D(k + i_1). \]

By (15), \[ a + y_{j_0} \in D(k) \] and by (19), \[ a + y_{j_0} \in D(k - i_1 + i_0). \] If \( i_1 \neq i_0 \), these two facts imply (17). If \( i_1 = i_0 \), it could also happen that

(21) \[ a + y_{j_0} \in D(k - i_0). \]

By Lemma 6, (19) and (21) together imply that

\[ a + y_{i_1} + y_{j_0} \in D(k + i_1), \]

which cannot happen, by Lemma 6 and (20). Thus, (21) does not hold, which means that (17) holds in this case also. This proves the first statement in the Lemma. The second is an obvious corollary of the first and of (8).

Since every \( H \in \mathcal{K} \) is a subgroup of \( K \), it is clear that \( L \) is also a subgroup. Let \( x, y \in G \) be such that \( x - y \in L \). By the definition of \( L \), \( A(x - y) = 0 \) for all \( A \in \mathcal{K} \). Define \( B = r_{-f(y)} \circ r_y \) and note that \( B(0) = 0 \) and \( B(x - y) = f(x) - f(y) \). For \( A \in \mathcal{K}, A(f(x) - f(y)) = AB(x - y) = 0 \) since \( AB \in \mathcal{K} \). Therefore \( f(x) - f(y) \in L \). We conclude that \( L \) is \( f \)-regular.

Let \( B \in \mathcal{K} \) and let \( B(G) = \{x_1, x_2, x_3\} \). Suppose \( x_i - x_j \in H \) where \( H \in \mathcal{K} \) and \( i \neq j \). For some \( A \in \mathcal{K}, Ar_{-x_j}(x_j) = 0 \) and \( Ar_{-x_j}(x_j) = A(x_j - x_j) = 0 \), which is impossible. Therefore \( x_1, x_2, x_3 \) are such that \( x_1 - x_j \notin \bigcup_{H \in \mathcal{K}} H \). Similarly, if \( x, y \in G \) are such that \( x - y \in K \) but \( x - y \notin \bigcup_{H \in \mathcal{K}} H \), then \( f(x) - f(y) \notin \bigcup_{H \in \mathcal{K}} H \). This shows that \( (L, K) \) is noncombinative of order \( V \) and thereby completes the proof of Theorem 3.

Remarks. It is an easy consequence of Theorem 3 that \( V = \delta \) if \( |G| = 4, 6 \) or 9. We were unable to extend Theorem 3 to any cases with \( V > 3 \). Note that Lemmas 4 and 5 hold for any \( V \), as does (8). It is not true in general that \( H = A^{-1}(0) \cap K \) is a group for any \( A \in \mathcal{K} \). In Example 5, \( H = \{0, 2, 4\} \) if \( A = f \). It may be that Theorem 3 is valid whenever \( V \) is prime. It this is the case, we could conclude that \( V = \delta \) whenever \( |G| \) is the product of two primes (not necessarily distinct).

Mathematical papers intended for publication in the Pacific Journal of Mathematics should be in typed form or offset-reproduced, (not dittoed), double spaced with large margins. Please do not use built up fractions in the text of the manuscript. However, you may use them in the displayed equations. Underline Greek letters in red, German in green, and script in blue. The first paragraph or two must be capable of being used separately as a synopsis of the entire paper. Please propose a heading for the odd numbered pages of less than 35 characters. Manuscripts, in triplicate, may be sent to any one of the editors. Please classify according to the scheme of Math. Reviews, Index to Vol. 39. Supply name and address of author to whom proofs should be sent. All other communications should be addressed to the managing editor, or Elaine Barth, University of California, Los Angeles, California, 90024.

50 reprints to each author are provided free for each article, only if page charges have been substantially paid. Additional copies may be obtained at cost in multiples of 50.

The Pacific Journal of Mathematics is issued monthly as of January 1966. Regular subscription rate: $102.00 a year (6 Vols., 12 issues). Special rate: $51.00 a year to individual members of supporting institutions.

Subscriptions, orders for numbers issued in the last three calendar years, and changes of address should be sent to Pacific Journal of Mathematics, P.O. Box 969, Carmel Valley, CA 93924, U.S.A. Old back numbers obtainable from Kraus Periodicals Co., Route 100, Millwood, NY 10546.
