CHEV ALLEY COHOMOLOGY FOR KONTSEVICH'S GRAPHS

Didier Arnal, Angela Gammella and Mohsen Masmoudi

Volume 218  No. 2  February 2005
We introduce the Chevalley cohomology for the graded Lie algebra of polyvector fields on \( \mathbb{R}^d \). This cohomology occurs naturally in the problem of construction and classification of formalities on the space \( \mathbb{R}^d \). Considering only graph formalities, that is, formalities defined with the help of graphs as in the original construction of Kontsevich, we define (as the first and third authors did earlier for the Hochschild cohomology) the Chevalley cohomology directly on spaces of graphs. More precisely, observing first a noteworthy property for Kontsevich’s explicit formality on \( \mathbb{R}^d \), we restrict ourselves to graph formalities with that property. With this restriction, we obtain some simple expressions for the Chevalley coboundary operator; in particular, we can write this cohomology directly on the space of purely aerial, nonoriented graphs. We also give examples and applications.

1. Introduction

In this article, we study formalities on the space \( \mathbb{R}^d \), which are defined as follows. Let \( T_{\text{poly}}(\mathbb{R}^d)[1] \) be the space of polyvector fields on \( \mathbb{R}^d \) graded by \( |\alpha| = \text{degree}(\alpha) = k - 2 \) if \( \alpha \) is a \( k \)-vector field (the [1] stands for this choice of translation on degrees). Similarly, \( D_{\text{poly}}(\mathbb{R}^d)[1] \) will denote the polydifferential operators on \( \mathbb{R}^d \) graded by \( |D| = m - 2 \) if \( D \) is an \( m \)-differential operator. We view both spaces as formal graded manifolds; see [Kontsevich 1997; 2003]. A formality is a formal nonlinear mapping \( \mathcal{F} \) between \( T_{\text{poly}}(\mathbb{R}^d)[1] \) and \( D_{\text{poly}}(\mathbb{R}^d)[1] \), intertwining their natural vector fields \( Q \) and \( Q' \).

The monomial functions \( \alpha_1 \cdot \alpha_2 \ldots \alpha_n \) on \( T_{\text{poly}}(\mathbb{R}^d) \) are elements of the space \( S^n(T_{\text{poly}}(\mathbb{R}^d)[1]) \) of symmetric \( n \)-polyvector fields on \( T_{\text{poly}}(\mathbb{R}^d)[1] \) (this means that \( \alpha_2 \cdot \alpha_1 = (-1)^{|\alpha_1| |\alpha_2|} \alpha_1 \cdot \alpha_2 \)). The manifold \( T_{\text{poly}}(\mathbb{R}^d)[1] \) is equipped with the formal bilinear vector field \( Q = Q_2 \), defined with the help of the Schouten bracket \( [\, , ]_S \):

\[
Q_2(\alpha_1 \cdot \alpha_2) = (-1)^{|\alpha_1| - 1 |\alpha_2|} [\alpha_1, \alpha_2]_S.
\]

Similarly, \( D_{\text{poly}}(\mathbb{R}^d)[1] \) is equipped with the formal vector field

\[
Q' = Q_1' + Q_2',
\]
defined by
\[ Q'_1(D_1) = -d_H D_1, \quad Q'_2(D_1 \cdot D_2) = (-1)^{(|D_1|-1)|D_2|} [D_1, D_2]_G. \]
Here \([ \cdot, \cdot ]_G\) is the Gerstenhaber bracket and \(d_H\) denotes the usual Hochschild coboundary operator: if \(D\) is an \(m\)-differential operator,
\[
d_H D(f_1, \ldots, f_{m+1}) = f_1 D(f_2, \ldots, f_{m+1}) - D(f_1 f_2, \ldots, f_{m+1}) + \cdots + (-1)^m D(f_1, \ldots, f_m) f_{m+1}
\]
A formality \(\mathcal{F}\) is then given by a sequence of mappings
\[
\mathcal{F}_n : S^n(T_{\text{poly}}(\mathbb{R}^d))[1] \to D_{\text{poly}}(\mathbb{R}^d)[1],
\]
homogeneous of degree 0 and satisfying the formality equation
\[
d_H(\mathcal{F}_n)(\alpha_1 \ldots \alpha_n) = \frac{1}{2} \sum_{I \cup J=\{1, \ldots, n\}, |I| \neq 0, |J| \neq 0} \epsilon_\alpha(I, J) Q'_2(\mathcal{F}_{|I|}(\alpha_I) \cdot \mathcal{F}_{|J|}(\alpha_J))
- \frac{1}{2} \sum_{k \neq \ell} \epsilon_\alpha(k\ell, 1 \ldots \hat{k} \ldots \hat{\ell} \ldots n) \mathcal{F}_{n-1}(Q_2(\alpha_k \cdot \alpha_\ell) \cdot \alpha_1 \ldots \alpha_{\hat{k}} \alpha_{\hat{\ell}} \ldots \alpha_n).
\]
Here, if \(I = \{i_1 < \cdots < i_\ell\}\), the notation \(\alpha_I\) means \(\alpha_{i_1} \ldots \alpha_{i_\ell}\).

We shall impose moreover the condition that \(\mathcal{F}_1\) is the canonical mapping \(\mathcal{F}_1^{(0)}\) from \(T_{\text{poly}}(\mathbb{R}^d)\) to \(D_{\text{poly}}(\mathbb{R}^d)\) defined by
\[
\mathcal{F}_1^{(0)}(\xi_1 \wedge \cdots \wedge \xi_n)(f_1, \ldots, f_n) = \frac{1}{n!} \sum_{\sigma \in S_n} \epsilon(\sigma) \prod_{i=1}^n \xi_{\sigma(i)}(f_i),
\]
for any vector field \(\xi_k\) and any function \(f_i\).

Now choose a coordinate system \((x_i)\) on \(\mathbb{R}^d\). M. Kontsevich [2003] has built explicitly a formality \(\mathcal{U}\) for \(\mathbb{R}^d\), using families of graphs drawn on configuration spaces. A graph \(\Gamma\) has aerial and terrestrial vertices. The aerial vertices are labeled \(p_1, \ldots, p_n\) and are elements of the Poincaré half-plane
\[
\mathcal{H} = \{z \in \mathbb{C} : \text{Im} z > 0\}.
\]
The terrestrial vertices \(q_1 < \cdots < q_m\) are on the real line. The edges of \(\Gamma\) are arrows starting from an aerial vertex and ending in a terrestrial or aerial vertex; there are no arrows of the form \(\overrightarrow{p_i p_i}\) and no multiple arrows. If we fix a total ordering \(O\) on the edges of \(\Gamma\), we get an oriented graph \((\Gamma, O)\). We say that \(O\) is compatible if, for all \(i\), the arrows starting from \(p_i\) precede those starting from \(p_{i+1}\). We denote by \(GO_{n,m}\) the set of oriented graphs \((\Gamma, O)\) with \(n\) labeled aerial vertices and \(m\) labeled terrestrial vertices, and such that \(O\) is compatible.
Consider such an oriented graph \((\Gamma, O) \in GO_{n,m}\). Suppose there are \(k_i\) edges starting from the vertex \(p_i\) (\(1 \leq i \leq n\)). Kontsevich [2003] defines a natural operator \(B_{(\Gamma, O)}\) assigning an \(m\)-differential operator \(B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n)\) to an \(n\)-uple \((\alpha_1, \ldots, \alpha_n)\) of polyvector fields \(\alpha_i\). This operator vanishes unless, for each \(i\), \(\alpha_i\) belongs to \(T^{k_i-1}_{\text{poly}}(\mathbb{R}^d)\) (\(\alpha_i\) is a \(k_i\)-polyvector field). We first consider all the multi-indexes \((t_1, \ldots, t_{[k]}\)) with \(|k| = \sum k_i\) and \(1 \leq t_r \leq d\) for all \(1 \leq r \leq |k|\). We denote by \(\text{end}(a)\) the set of edges ending at the vertex \(a\); if these edges are \(e_1, \ldots, e_t\), we let \(\partial_{\text{end}(a)}\) be the operator

\[
\partial_{\text{end}(a)} = \frac{\partial^{t}}{\partial x_{t_1} \cdots \partial x_{t_{t}}}
\]

Then, we denote by \(\text{strt}(p_i)\) the ordered set \(e_1^j < \cdots < e_{h_{j}}\) of edges starting from \(p_i\) and, if \(\alpha_i\) is a \(k_i\)-vector field, by \(\alpha_i^{\text{strt}(p_i)}\) the following component of \(\alpha_i\):

\[
\alpha_i^{\text{strt}(p_i)} = \alpha_i^{i_1 \cdots i_{h_{j}}}
\]

Finally, if \(\alpha_i\) is a \(k_i\)-vector field for each \(i\), we set

\[
B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n)(f_1, \ldots, f_m) = \sum_{1 \leq t_1, \ldots, t_{[k]} \leq d} \prod_{i=1}^{n} \partial_{\text{end}(p_i)} \alpha_i^{\text{strt}(p_i)} \prod_{j=1}^{m} \partial_{\text{end}(q_j)} f_j.
\]

\(B_{(\Gamma, O)}\) will be called the graph operator associated with \((\Gamma, O)\).

The explicit formality \(\mathcal{Q}\) of Kontsevich can now be written as a sum \(\mathcal{Q} = \sum_{n} \mathcal{Q}_n\) with

\[
\mathcal{Q}_n = \sum_{m \geq 0} \sum_{(\Gamma, O) \in GO_{n,m}} w_{(\Gamma, O)} B_{(\Gamma, O)},
\]

where the coefficient \(w_{(\Gamma, O)}\), the weight of \((\Gamma, O)\), is an integral on a compactified configuration space. To be precise, for \(2n + m - 2 \geq 0\), let \(\text{Conf}(n, m)\) be the space of \((n+m)\)-tuples consisting of \(n\) distinct points \(p_i\) in \(\mathcal{H}\) and \(m\) distinct points \(q_j\) on the real line \(\partial \mathcal{H}\). Consider on \(\text{Conf}(n, m)\) the action of the group \(G\) of transformations \(z \mapsto az + b\) \((a > 0 \text{ and } b \text{ real})\), and form the quotient space

\[
C_{n,m} = \text{Conf}(n, m) / G.
\]

Kontsevich associates with each oriented graph \((\Gamma, O)\) the form

\[
\omega_{(\Gamma, O)} = \frac{1}{k!} \bigwedge_{i=1}^{n} (d \Phi_{e_1} \wedge \cdots \wedge d \Phi_{e_{k_i}})
\]
on $C_{n,m}$, where $\{e_1^i < e_2^i < \cdots < e_{k_i}^i\}$ denotes the ordered set $\text{str}(p_i)$ formed by the $k_i$ edges starting from $p_i$, $k_i := k_1! \cdots k_n!$ and, if $e_i^j = \overrightarrow{p_i} a$,

$$\Phi_{e_i} = \Phi_{\overrightarrow{p_i} a} = \frac{1}{2\pi} \text{Arg} \frac{a - p_i}{a - \overrightarrow{p_i}}.$$ 

The weight $w_{(\Gamma,O)}$ is then defined as the value of the integral $\omega_{(\Gamma,O)}$ on the connected component $C_{n,m}^{+}$ of $C_{n,m}$ for which $q_1 < \cdots < q_m$.

In this work, we are looking for graph formalities, that is, formalities on the space $\mathbb{R}^d$ of the form $\mathcal{F} = \sum_n \mathcal{F}_n$, where the $\mathcal{F}_n$ are homogeneous mappings (of degree 0) of the form

$$\mathcal{F}_n = \sum_{m \geq 0} \sum_{(\Gamma,O) \in \text{GO}_{n,m}} c_{(\Gamma,O)} B_{(\Gamma,O)},$$

with real coefficients $c_{(\Gamma,O)}$. We shall use the notation $\gamma_n = B_{\gamma_n}$, where $\gamma_n$ is the linear combination

$$\gamma_n = \sum_{m \geq 0} \sum_{(\Gamma,O) \in \text{GO}_{n,m}} c_{(\Gamma,O)} (\Gamma, O).$$

Now assume we have found $\mathcal{F}_1, \ldots, \mathcal{F}_{n-1}$ (with $\mathcal{F}_1 = \mathcal{F}_1^{(0)} = \mathcal{U}_1$) such that the formality equation holds up to order $n - 1$. The next term $\mathcal{F}_n$, if it exists, must be a solution of an equation

$$d_H \circ \mathcal{F}_n = E_n,$$

that is,

$$d_H (\mathcal{F}_n (\alpha_1, \ldots, \alpha_n)) = E_n (\alpha_1, \ldots, \alpha_n) = E_n (\alpha_{(1, \ldots, n)}),$$

where $E_n (\alpha_{(1, \ldots, n)})$ is a Hochschild cocycle. The Hochschild cohomology is localized in $T_{\text{poly}}(\mathbb{R}^d)[1]$; more precisely, the total skewsymmetrization $a \circ E_n (\alpha_{(1, \ldots, n)})$ of $E_n (\alpha_{(1, \ldots, n)})$ is a polydifferential operator of order 1, \ldots, 1, that is, the image under $\mathcal{F}_1^{(0)}$ of a polyvector field. Moreover, there exists an operator $A_n$ such that

$$E_n (\alpha_{(1, \ldots, n)}) = (a \circ E_n + d_H \circ A_n) (\alpha_{(1, \ldots, n)}).$$

Now put

$$\varphi_n = \mathcal{F}_1^{-1} \circ a \circ E_n,$$

that is,

$$\varphi_n (\alpha_{(1, \ldots, n)}) = \mathcal{F}_1^{-1} (a (E_n (\alpha_{(1, \ldots, n)})));$$

then $\varphi_n : S^n (T_{\text{poly}}(\mathbb{R}^d)[1]) \rightarrow T_{\text{poly}}(\mathbb{R}^d)[1]$ is homogeneous of degree $|\varphi_n| = 1$.

In Section 2, we define the Chevalley coboundary operator $\partial$ on $T_{\text{poly}}(\mathbb{R}^d)$. We show that the mapping $\varphi_n$ described above is a Chevalley cocycle, and, if it is a coboundary ($\varphi_n = \partial \phi_{n-1}$), we can add to $\mathcal{F}_{n-1}$ a Hochschild coboundary so that
\(\alpha(E_n)\) vanishes and thus find a \(\mathcal{F}_n\) for which the formality equation holds up to order \(n\).

In Section 3, we establish a noteworthy property for the Kontsevich weights. For any graph \(\Gamma\) (with \(k_i\) edges starting from \(p_i\)), denote by \(\Delta\) the purely aerial graph obtained by removing the legs \(\overrightarrow{pq}_j\) and the feet \(q_j\) of \(\Gamma\), and by \(\ell_i\) the number of aerial edges starting from \(p_i\). We prove that

\[
\alpha \left( \sum_{(\Gamma, O) \in \text{GO}_{n,m}^{(1)}} w_{(\Gamma, O)} B_{(\Gamma, O)} \right) = \sum_{(\Delta, O_\Delta) \in \text{GO}_{n}^{(0)}} w_{(\Delta, O_\Delta)} \frac{1}{m!} \sum_{(\Gamma, O) \in \text{GO}_{n,m}^{(1)}} \frac{\ell!}{k!} \epsilon(\Gamma) B_{(\Gamma, O)}.
\]

Here \(\text{GO}_{n,m}^{(1)}\) denotes the subspace of \(\text{GO}_{n,m}\) formed by the oriented graphs having exactly one leg for each foot, \(\text{GO}_{n}^{(0)}\) is the set of purely aerial oriented graphs \((\Delta, O_\Delta)\) with \(n\) aerial vertices and \(O_\Delta\) compatible and \(\epsilon(\Gamma)\) is an explicit sign depending only on \(\Gamma\).

This property suggests that we study what we call \(K\)-graph formalities. A \(K\)-graph formality up to order \(n\) is a graph formality \(\mathcal{F}\) at order \(n - 1\) such that \(\varphi_n = \mathcal{F}^{-1} \circ \alpha \circ E_n\) has the form

\[
\varphi_n = \sum_{(\Delta, O_\Delta) \in \text{GO}_{n}^{(0)}} c_{(\Delta, O_\Delta)} C_{(\Delta, O_\Delta)}
\]

with real coefficients \(c_{(\Delta, O_\Delta)}\) and where

\[
C_{(\Delta, O_\Delta)} = \sum_{m \geq 0} \frac{1}{m!} \sum_{(\Gamma, O) \in \text{GO}_{n,m}^{(1)}} \frac{\ell!}{k!} \epsilon(\Gamma) B_{(\Gamma, O)}.
\]

In Section 4 we give some simple expressions of our Chevalley coboundary operator. Then we restrict ourselves to \(K\)-graph formalities and study the Chevalley cohomology related to the question of building such formalities.

In Section 5 we show that the coboundary operator \(\partial\) can be written directly on the aerial part of the graphs.

We devote Section 6 to explicit computations and applications. In particular, we prove the triviality of the cohomology for small values of \(n\) and give the restriction of the cohomology for linear formalities.

2. Chevalley cohomology and formalities

We start by defining a graded Chevalley cohomology in a general algebraic setting — that is, for cochains \(C : S^n(g[1]) \to \mathfrak{M}[1]\), where \(g\) is a graded Lie algebra and \(\mathfrak{M}\) a graded \(g\)-module. In fact two Chevalley coboundary operators are naturally associated with the formality equation for \(\mathbb{R}^d\). The first, \(\partial'\), is obtained
by endowing \(D_{\text{poly}}(\mathbb{R}^d)\) with a \(T_{\text{poly}}(\mathbb{R}^d)\)-graded module structure; cochains are mappings \(C : S^a(T_{\text{poly}}(\mathbb{R}^d)[1]) \to D_{\text{poly}}(\mathbb{R}^d)[1]\). The other one, \(\partial\), is obtained by considering \(T_{\text{poly}}(\mathbb{R}^d)\) as a graded module over itself; cochains are mappings \(C : S^a(T_{\text{poly}}(\mathbb{R}^d)[1]) \to T_{\text{poly}}(\mathbb{R}^d)[1]\). Using both \(\partial\) and \(\partial'\), we show that the obstructions to formalities can be interpreted as cocycles for \(\partial\).

2.1. Chevalley cohomology. Let \((g, [\ , \ ]_g)\) be a graded Lie algebra and \(\mathcal{M}\) a graded module over \(g\). For reasons of homogeneity, we prefer to work with \(g[1]\) and \(\mathcal{M}[1]\).

Thus, we replace \([\ , \ ]\) and the action of \(g\) on \(\mathcal{M}\) respectively by \([\ , \ ]_1^g\) and \([\ , \ ]_{\mathcal{M}}^g\), defined for homogeneous \(\alpha, \beta \in g[1]\) of degrees \(|\alpha|, |\beta|\) and for \(m \in \mathcal{M}[1]\) of degree \(|m|\) by

\[
[\alpha, \beta]' = (-1)^{|\alpha|+1}|\beta|[\alpha, \beta],
\]

\]

\[
[\alpha, m]_{\mathcal{M}} = (-1)^{|\alpha|+1}|\alpha|m.
\]

The space \(C^n(g, \mathcal{M})\) of \(n\)-cochains consists of mappings \(C\) from \(S^n(g[1])\) to \(\mathcal{M}[1]\). The Chevalley coboundary \(\partial C\) of an \(n\)-cochain \(C\), homogeneous of degree \(|C|\), is the \((n+1)\)-cochain defined by

\[
\partial C(\alpha_1 \ldots \alpha_{n+1}) = \sum_{i=1}^{n+1} (-1)^{|C||\alpha_i|} \epsilon_\alpha(i, 1 \ldots \hat{i} \ldots n + 1) \bigl[\alpha_i, C(\alpha_1 \ldots \hat{i} \ldots \alpha_{n+1})\bigr]_{\mathcal{M}}
\]

\[
- \frac{1}{2} \sum_{i \neq j} \epsilon_\alpha(ij, 1 \ldots \hat{i} \ldots \hat{j} \ldots n + 1)(-1)^{|C|} C([\alpha_i, \alpha_j]' \cdot \alpha_1 \ldots \hat{i} \alpha_i \ldots \hat{j} \alpha_j \ldots \alpha_{n+1}).
\]

Here the \(\alpha_i\) are homogeneous elements of \(g\), \(|\alpha_i|\) denotes the degree of \(\alpha_i\) in \(g[1]\) and for any permutation \(\sigma\) of \(\{1, \ldots, n\}\), \(\epsilon_\sigma(\sigma)\) is the sign of \(\sigma\) in the graded sense.

We shall denote by \(C^n_{[1]}(g, \mathcal{M})\) the subspace of \(C^n(g, \mathcal{M})\) formed by the \(n\)-cochains of degree \(q\) and by \(H^n_{[1]}(g, \mathcal{M})\) the corresponding cohomology group. Note that \(\partial\) sends \(C^n_{[q]}(g, \mathcal{M})\) into \(C^{n+1}_{[q+1]}(g, \mathcal{M})\).

Extending usual techniques to the graded case (See Gammella 2001 for an explicit computation), it is possible to prove:

**Lemma 2.1.** The operator \(\partial\) is a cohomology operator, that is, \(\partial^2 = \partial \circ \partial = 0\).

We now return to the graded Lie algebras

\[
(T_{\text{poly}}(\mathbb{R}^d), [\ , \]_S) \quad \text{and} \quad (D_{\text{poly}}(\mathbb{R}^d), [\ , \]_G),
\]

where \([\ , \]_S\) is the Schouten bracket and \([\ , \]_G\) the Gerstenhaber bracket. Let us first make our conventions for these spaces and brackets precise.
Let $\alpha$ be a $k$-vector field and $\{e_i\}$ the canonical basis of $\mathbb{R}^d$. We put
\[
\alpha = \sum_{j_1,\ldots,j_k} \alpha^{j_1\ldots j_k} e_{j_1} \otimes \cdots \otimes e_{j_k} = \sum_{j_1 < j_2 < \cdots < j_k} \alpha^{j_1\ldots j_k} e_{j_1} \wedge \cdots \wedge e_{j_k}
\]
\[
= \frac{1}{k!} \sum_{j_1\ldots j_k} \alpha^{j_1\ldots j_k} e_{j_1} \wedge \cdots \wedge e_{j_k}.
\]

For any $k_1$-vector field $\alpha_1$ and $k_2$-vector field $\alpha_2$ (the degree of $\alpha_i$ is $k_i - 1$ in $T_{\text{poly}}(\mathbb{R}^d)$), we define first a polyvector field $\alpha_1 \bullet \alpha_2$ with components
\[
\alpha_1 \bullet \alpha_2 = \frac{1}{k_1! k_2!} \sum_{\sigma \in S_{k_1+k_2-1}} \left( \varepsilon(\sigma) \sum_{\ell=1}^{k_1} \sum_{i=1}^{k_2} (-1)^{\ell-1} \sum_{j=1}^{d} \alpha_1^{i \sigma(\ell)} \cdots \alpha_2^{j \sigma(k_2-1)} \partial_{i} \alpha_2^{j \sigma(k_2) \cdots \sigma(k_2+1)} \right).
\]

Now, $[\alpha_1, \alpha_2]_S$ can be written as
\[
[\alpha_1, \alpha_2]_S = (-1)^{k_2(k_1-1)} \alpha_1 \bullet \alpha_2 - (-1)^{k_2-1} \alpha_2 \bullet \alpha_1.
\]
(This choice for the Schouten bracket is denoted $[\ , \ ]_S$ in [Arnal et al. 2002] and [Manchon and Torossian 2003].)

On the other hand, for any $m_1$-differential operator $D_1$ and any $m_2$-differential operator $D_2$ (the degree of $D_i$ is $m_i - 1$ in $D_{\text{poly}}(\mathbb{R}^d)$), we may write $[D_1, D_2]_G$ in the form
\[
[D_1, D_2]_G = D_1 \circ D_2 - (-1)^{(m_1-1)(m_2-1)} D_2 \circ D_1,
\]
where
\[
D_1 \circ D_2(f_1, \ldots, f_{m_1+m_2-1}) = \sum_{j=1}^{m_1} (-1)^{(m_2-1)(j-1)} D_1(f_1, \ldots, f_{j-1}, D_2(f_j, \ldots, f_{j+m_2-1}), f_{j+m_2}, \ldots, f_{m_1+m_2-1}).
\]

Recall the canonical mapping $\mathcal{F}_1^{(0)}$ from $T_{\text{poly}}(\mathbb{R}^d)$ into $D_{\text{poly}}(\mathbb{R}^d)$: each $k$-vector field $\alpha$ can be viewed as a $k$-differential operator $\mathcal{F}_1^{(0)}(\alpha)$ of order $1, \ldots, 1$:
\[
\left(\mathcal{F}_1^{(0)}(\alpha)\right)(f_1, \ldots, f_k) = \langle \alpha, df_1 \wedge \cdots \wedge df_k \rangle = \frac{1}{k!} \alpha^{i_1 \cdots i_k} \partial_{i_1} f_1 \cdots \partial_{i_k} f_k.
\]

Now consider the action of $T_{\text{poly}}(\mathbb{R}^d)$ given by
\[
\alpha.D = \alpha \circ [\mathcal{F}_1^{(0)}(\alpha), D]_G \quad \text{for} \ \alpha \in T_{\text{poly}}(\mathbb{R}^d) \ \text{and} \ D \in D_{\text{poly}}(\mathbb{R}^d),
\]
where \( a \) denotes the usual skewsymmetrization of differential operators and \( [ \cdot, \cdot ]_G \) is the Gerstenhaber bracket. This action defines a \( T_{\text{poly}}(\mathbb{R}^d) \)-graded module structure on \( D_{\text{poly}}(\mathbb{R}^d) \). Indeed, one can prove:

**Proposition 2.2.** The following equalities hold for any \( D_1, D_2, D \) in \( D_{\text{poly}}(\mathbb{R}^d) \), any \( k_1 \)-vector field \( \alpha_1 \) and \( k_2 \)-vector field \( \alpha_2 \) in \( T_{\text{poly}}(\mathbb{R}^d) \):

(i) \( a \circ [D_1, D_2]_G = a \circ [D_1, a \circ D_2]_G \);

(ii) \( \mathcal{F}_1^{(0)}([\alpha_1, \alpha_2]_S) = a \circ [\mathcal{F}_1^{(0)}(\alpha_1), \mathcal{F}_1^{(0)}(\alpha_2)]_G \);

(iii) \( a \circ [\mathcal{F}_1^{(0)}(\{\alpha_1, \alpha_2\}_S), D]_G = a \circ [\mathcal{F}_1^{(0)}(\alpha_1), a \circ [\mathcal{F}_1^{(0)}(\alpha_2), D]_G]_G \)

\(-(-1)^{(k_1-1)(k_2-1)}a \circ [\mathcal{F}_1^{(0)}(\alpha_2), a \circ [\mathcal{F}_1^{(0)}(\alpha_1), D]_G]_G \).

From (iii) it follows that

\[ [\alpha_1, \alpha_2]_S \circ D = \alpha_1 \circ (\alpha_2 \circ D) - (-1)^{(k_1-1)(k_2-1)} \alpha_2 \circ (\alpha_1 \circ D), \]

and thus \( D_{\text{poly}}(\mathbb{R}^d) \) is a \( T_{\text{poly}}(\mathbb{R}^d) \)-module.

Now endow \( D_{\text{poly}}(\mathbb{R}^d) \) with the \( T_{\text{poly}}(\mathbb{R}^d) \)-graded structure described above. If \( C : \bigwedge^n T_{\text{poly}}(\mathbb{R}^d) = S^n T_{\text{poly}}(\mathbb{R}^d)[1] \rightarrow D_{\text{poly}}(\mathbb{R}^d)[1] \) is a homogeneous mapping of degree \( |C| \), we can define its Chevalley coboundary \( \partial'C \). The latter can be written using the vector fields \( Q \) and \( Q' \), associated respectively with \( T_{\text{poly}}(\mathbb{R}^d) \) and \( D_{\text{poly}}(\mathbb{R}^d) \):

\[ \partial' C (\alpha_1 \ldots \alpha_{n+1}) \]

\[ = \sum_{i=1}^{n+1} (-1)^{|C|+1} \varepsilon_{\alpha}(i, 1 \ldots \hat{i} \ldots n+1) a \circ Q'_{\alpha}(\mathcal{F}_1^{(0)}(\alpha_i)) \cdot C(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1}) \]

\[ - \frac{1}{2} \sum_{i \neq j} \varepsilon_{\alpha}(i, j, 1 \ldots \hat{i} \ldots \hat{j} \ldots n+1) (-1)^{|C|} C(Q_2(\alpha_i \cdot \alpha_j) \cdot \alpha_1 \ldots \hat{\alpha}_i \hat{\alpha}_j \ldots \alpha_{n+1}). \]

To simplify the writing, we will sometimes write \( \alpha_i \) instead of \( \mathcal{F}_1^{(0)}(\alpha_i) \).

At the same time, considering \( T_{\text{poly}}(\mathbb{R}^d) \) as a graded module over itself, one can define the Chevalley cohomology for \( T_{\text{poly}}(\mathbb{R}^d) \). If \( C : S^n T_{\text{poly}}(\mathbb{R}^d)[1] \rightarrow T_{\text{poly}}(\mathbb{R}^d)[1] \) is an \( n \)-cochain, homogeneous of degree \( |C| \), its coboundary \( \partial C \) is

\[ \partial C (\alpha_1 \ldots \alpha_{n+1}) \]

\[ = \sum_{i=1}^{n+1} (-1)^{|C|+1} \varepsilon_{\alpha}(i, 1 \ldots \hat{i} \ldots n+1) Q_2(\alpha_i \cdot C(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1})) \]

\[ - \frac{1}{2} \sum_{i \neq j} \varepsilon_{\alpha}(i, j, 1 \ldots \hat{i} \ldots \hat{j} \ldots n+1) (-1)^{|C|} C(Q_2(\alpha_i \cdot \alpha_j) \cdot \alpha_1 \ldots \hat{\alpha}_i \hat{\alpha}_j \ldots \alpha_{n+1}). \]
Remark. For any $\varphi : S^d (T_{pol} (\mathbb{R}^d) [1]) \to T_{pol} (\mathbb{R}^d) [1]$, we have

$$\partial' (\mathcal{F}_1 (0) \circ \varphi) = \mathcal{F}_1 (0) \circ \partial \varphi.$$ 

2.2. Obstruction to formalities. The two Chevalley coboundary operators $\partial$ and $\partial'$ enable us to reformulate the formality equation. Indeed, suppose we want to construct a formality $\mathcal{F}$ from $T_{pol} (\mathbb{R}^d)$ to $D_{pol} (\mathbb{R}^d)$. We thus need to solve recursively the formality equation (see [Kontsevich 1997; Arnal et al. 2002] for notations)

$$d_H (\mathcal{F}_n) (\alpha_1 \ldots \alpha_n) = \frac{1}{2} \sum_{I \cup J = \{1, \ldots, n\}, |I| \geq 1, |J| \geq 1} \varepsilon_\alpha (I, J) Q^2_2 (\mathcal{F}_{|I|} (\alpha_I) \cdot \mathcal{F}_{|J|} (\alpha_J))$$

$$- \frac{1}{2} \sum_{k \neq \ell} \varepsilon_\alpha (k, \ell, 1 \ldots \hat{k} \ell \ldots n) \mathcal{F}_{n-1} (Q_2 (\alpha_k \cdot \alpha_\ell) \cdot \alpha_1 \ldots \hat{k} \alpha_\ell \partial \ldots \alpha_n),$$

where $d_H$ is the Hochschild coboundary operator.

Now impose the condition that the first component $\mathcal{F}_1$ be $\mathcal{F}_1 (0)$. Assume there are mappings $\mathcal{F}_2, \ldots, \mathcal{F}_{n-1}$, homogeneous of degree 0, and satisfying the formality equation up to order $n-1$. Denote by $E_n$ the right-hand side of the equation at the order $n$. Then $E_n$ is a Hochschild cocycle: $d_H E_n = 0$ (see [Arnal and Masmoudi 2002] for instance). Thus

$$E_n = a \circ E_n + d_H C,$$

where $a \circ E_n$ is a differential operator of order 1, $\ldots, 1$ and $E_n$ is a coboundary if and only if $a \circ E_n = 0$. But

$$a \circ E_n (\alpha_1 \ldots \alpha_n) = \partial' a \mathcal{F}_{n-1} (\alpha_1 \ldots \alpha_n) + a R_n (\alpha_1 \ldots \alpha_n),$$

where

$$R_n (\alpha_1 \ldots \alpha_n) = \frac{1}{2} \sum_{I \cup J = \{1, \ldots, n\}, |I| \geq 2, |J| \geq 2} \varepsilon_\alpha (I, J) Q^2_2 (\mathcal{F}_{|I|} (\alpha_I) \cdot \mathcal{F}_{|J|} (\alpha_J)).$$

It follows directly from this expression that $R_n$ and $a \circ R_n$ both have degree 1: $|R_n| = |a \circ R_n| = 1$. Moreover,

Theorem 2.3. The skewsymmetrization $a \circ E_n$ of $E_n$ can be identified through the inverse mapping of $\mathcal{F}$ with a $\partial$-cocycle. If this cocycle is exact, we can find $\mathcal{F}'_{n-1}$ and $\mathcal{F}'_n$, homogeneous of degree 0, such that $\mathcal{F}_2, \ldots, \mathcal{F}_{n-2}, \mathcal{F}'_{n-1}, \mathcal{F}'_n$ satisfy the formality equation up to order $n$.

Proof. The proof proceeds in three steps.
Step 1. First we check that $a \circ R_{n}$ is a cocycle for $\partial'$:

\[
\partial' a R_{n}(\alpha_{1}, \ldots, \alpha_{n+1})
\]

\[
= \sum_{i=1}^{n+1} (-1)^{|\alpha_{i}|} \varepsilon_{\alpha}(i, 1 \ldots \hat{i} \ldots n + 1) a Q'_{2}(\alpha_{i} \cdot a R_{n}(\alpha_{1}, \ldots, \hat{\alpha}_{i}, \ldots, \alpha_{n+1}))
\]

\[
+ \frac{1}{2} \sum_{i \neq j} \varepsilon_{\alpha}(i j, 1 \ldots \hat{i} \hat{j} \ldots n + 1) a R_{n}(Q_{2}(\alpha_{i}, \alpha_{j}) \cdot \alpha_{1}, \ldots, \hat{\alpha}_{i} \hat{\alpha}_{j}, \ldots, \alpha_{n+1})
\]

\[
= \frac{1}{2} \sum_{i=1}^{n+1} \left( (-1)^{|\alpha_{i}|} \varepsilon_{\alpha}(i, 1 \ldots \hat{i} \ldots n + 1) \right.
\]

\[
\times \sum_{I \cup J = [1, i, \ldots, n + 1]} \varepsilon_{\alpha'}(I, J) a Q'_{2}(\alpha_{i} \cdot a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j})))
\]

\[
+ \frac{1}{4} \sum_{i \neq j} \left( \varepsilon_{\alpha}(i j, 1 \ldots \hat{i} \hat{j} \ldots n + 1) \right.
\]

\[
\times \sum_{I \cup J = [0, 1, \ldots, n + 1]} \varepsilon_{\alpha'}(I, J) a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j})))
\]

\[
= \frac{1}{2} (I) + \frac{1}{4} (II),
\]

where we have set $\alpha_{0} := Q_{2}(\alpha_{i} \cdot \alpha_{j})$, $\varepsilon_{\alpha'} := \varepsilon_{\alpha \setminus \{\alpha_{i}\}}$ and $\varepsilon_{\alpha'} := \varepsilon_{(\alpha \cup \{\alpha_{0}\}) \setminus \{\alpha_{i}, \alpha_{j}\}}$.

The term (I) above equals

\[
\sum_{i=1}^{n+1} \sum_{I \cup J = [1, i, \ldots, n + 1]} (-1)^{|\alpha_{i}| + |\alpha_{j}|} \varepsilon_{\alpha}(i, 1, I) a Q'_{2}(a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j}))) \cdot \alpha_{i})
\]

By Proposition 2.2, $a Q'_{2}$ satisfies the graded Jacobi identity; thus (I) equals

\[
- \sum_{i=1}^{n+1} \sum_{I \cup J = [1, i, \ldots, n + 1]} (-1)^{|\alpha_{j}||\alpha_{i}| + |\alpha_{i}|} \varepsilon_{\alpha}(i, 1, J) a Q'_{2}(a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{j}) \cdot \alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j}))
\]

\[
- \sum_{I \cup J = [1, i, \ldots, n + 1]} \varepsilon_{\alpha}(i, 1, J) a Q'_{2}(a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j})))
\]

\[
= -2 \sum_{I \cup J = [1, \ldots, n + 1]} \varepsilon_{\alpha}(i, 1, J) a Q'_{2}(a Q'_{2}(\mathcal{F}_{I|J}(\alpha_{i}) \cdot \mathcal{F}_{I|J}(\alpha_{j}))).
\]
Similarly, the second term, (II), is equal to

\[
\sum_{i \neq j} \epsilon_a (i, j, 1 \ldots i \ldots n + 1) \sum_{I \cup J = [0, 1 \ldots i \ldots n+1]} \epsilon_a (I, J) aQ_2^r \left( \mathcal{F}_{|I|}(\alpha_i). \mathcal{F}_{|J|}(\alpha_j) \right) \\
= \sum_{i \neq j} \sum_{I = I_1 \cup [0]} \sum_{\substack{J = J_1 \cup [0] \\mid I \cup J = [1 \ldots i \ldots n+1] \\mid |I| \geq 2, |J| \geq 2}} \epsilon_a (i, j, I_1, J_1) aQ_2^r \left( \mathcal{F}_{|I_1|}(\alpha_i). \mathcal{F}_{|J_1|}(\alpha_j) \right) \\
+ \sum_{i \neq j} \left( \sum_{J = J_1 \cup [0]} \sum_{\substack{I = I_1 \cup [0] \\mid I \cup J = [1 \ldots i \ldots n+1] \\mid |I| \geq 2, |J| \geq 2}} \epsilon_a (i, j, I_1, J_1) (-1)^{|I|+|J|} aQ_2^r \left( \mathcal{F}_{|I_1|}(\alpha_i). \mathcal{F}_{|J_1|}(\alpha_j) \right) \right) \\
= 2 \sum_{i \neq j} \sum_{I = I_1 \cup [0]} \sum_{\substack{J = J_1 \cup [0] \\mid I \cup J = [1 \ldots i \ldots n+1] \\mid |I| \geq 2, |J| \geq 2}} \epsilon_a (i, j, I_1, J_1) aQ_2^r \left( \mathcal{F}_{|I_1|}(\alpha_i). \mathcal{F}_{|J_1|}(\alpha_j) \right).
\]

Putting (I) and (II) together, we get

\[
\partial^r (aR_n)(\alpha_1 \ldots \alpha_{n+1}) = \frac{1}{2}(I) + \frac{1}{4}(II)
\]

\[
= \sum_{I' \cup J = [1 \ldots n+1]} \sum_{|I'| \geq 2, |I'| \geq 3} \epsilon_a (I', J) \left( \sum_{i \in I'} \epsilon_a (i, I) aQ_2^r \left( aQ_2^r (\alpha_i). \mathcal{F}_{|I|}(\alpha_i) \right) \right) \\
+ \frac{1}{2} \sum_{i \neq j \in I', I' \cup J = I \cup [j]} \epsilon_a (i, j, I_1) aQ_2^r \left( \mathcal{F}_{|I_1|}(\alpha_i). \mathcal{F}_{|J_1|}(\alpha_j) \right).
\]

Now, Proposition 2.2 and the definition of \( \partial^r \) yield

\[
\partial^r (aR_n)(\alpha_1 \ldots \alpha_{n+1}) = - \sum_{I' \cup J = [1 \ldots n+1]} \sum_{|I'| \geq 2, |J| \geq 2} \epsilon_a (I, J) aQ_2^r \left( \partial^r a\mathcal{F}_{|J|-1}(\alpha_{J'}). \mathcal{F}_{|I|}(\alpha_I) \right).
\]

On the other hand, since the formality equation holds up to order \( n - 1 \), we have

\[
\partial^r a\mathcal{F}_{p-1} + aR_p = a(E_p) = a(d_H(\mathcal{F}_p)) = 0 \quad \text{for} \; p \leq n - 1.
\]
But \(|I'| \leq n - 1\) for all \(I'\) in the expression \(\ast\); thus

\[-\partial' a_{|I'|-1}(\alpha_I) = a_{|I'|}(\alpha_I) = \frac{1}{2} \sum_{S \cup T = I', |S| \geq 2, |T| \geq 2} \varepsilon_{a_{S,T}}(S, T) a_{Q_2}(\mathcal{F}_{|S|}(\alpha_S) \cdot \mathcal{F}_{|T|}(\alpha_T)).\]

Finally, \(\ast\) becomes

\[
\partial'(a_{R_n})(\alpha_1 \ldots \alpha_{n+1}) \\
= \frac{1}{2} \sum_{S \cup T \cup J = [1 \ldots n+1], |S| \geq 2, |T| \geq 2, |J| \geq 2} \varepsilon_{a}(S \cup T) \varepsilon_{a_{S,T}}(S, T) \times a_{Q_2}(a_{Q_2}(\mathcal{F}_{|S|}(\alpha_S) \cdot \mathcal{F}_{|T|}(\alpha_T)) \cdot \mathcal{F}_{|J|}(\alpha_J)) \\
= \frac{1}{2} \sum_{S \cup T \cup J = [1 \ldots n+1], |S| \geq 2, |T| \geq 2, |J| \geq 2} \varepsilon_{a}(S, T, J) a_{Q_2}(a_{Q_2}(\mathcal{F}_{|S|}(\alpha_S) \cdot \mathcal{F}_{|T|}(\alpha_T)) \cdot \mathcal{F}_{|J|}(\alpha_J)).
\]

Thanks to the Jacobi identity, the quantity on the last line vanishes. Hence \(\partial'(a_{R_n})\) and \(\partial'(a_{E_n})\) both vanish.

Step 2. Put

\[\varphi_n = \mathcal{F}_1^{-1} \circ a \circ E_n.\]

Since

\[\partial'(a \circ E_n) = \partial'(\mathcal{F}_1(\varphi_n)) = \mathcal{F}_1(\partial \varphi_n) = 0,\]

\(\varphi_n\) is a cocycle for \(\partial\).

Step 3. Assume that \(\varphi_n = \partial \phi_{n-1}\), where \(\phi_{n-1} : S^{n-1}(T_{\text{poly}}(\mathbb{R}^d)[1]) \rightarrow T_{\text{poly}}(\mathbb{R}^d)[1]\). Of course, \(d_H \mathcal{F}_1(\phi_{n-1}) = 0\). Therefore, the mappings \(\mathcal{F}_2 = \mathcal{F}_2, \ldots, \mathcal{F}_{n-2} = \mathcal{F}_{n-2}, \mathcal{F}_{n-1} = \mathcal{F}_{n-1} - \mathcal{F}_1 \circ \phi_{n-1}\) satisfy the formality equation up to order \(n-1\). Moreover, the Hochschild cocycle \(E'_n\) corresponding to these \(\mathcal{F}_p\) satisfies

\[a \circ E'_n = a \circ E_n - \partial'(\mathcal{F}_1 \circ \phi_{n-1}) = a \circ E_n - \mathcal{F}_1(\partial \phi_{n-1}) = 0.\]

We are now able to find \(\mathcal{F}'_n\) such that \(E'_n = d_H \mathcal{F}'_n\). This ends the proof.

\[\square\]

3. Skewsymmetrization

The aim of this section is to prove a noteworthy property of Kontsevich’s weights and the definition of \(K\)-graph formalities.

3.1. Skewsymmetrization and 1-graphs. Consider an \(m\)-differential operator \(D\) on \(\mathbb{R}^d\), vanishing on constants. We can decompose \(D\) as

\[D = D^{(1)} + D^{(>1)},\]
where $D^{(1)}$ has order 1 in each of its arguments and $D^{(>1)}$ has order greater than 1 in at least one of its arguments. The skewsymmetrization $a(D)$ of $D$, defined by

$$a(D)(f_1, \ldots, f_m) = \frac{1}{m!} \sum_{\sigma \in S_m} \varepsilon(\sigma) D(f_{\sigma^{-1}(1)}, \ldots, f_{\sigma^{-1}(m)}),$$

satisfies $a(D) = a(D^{(1)}) + a(D^{(>1)})$, and therefore

$$a(D)^{(1)} = a(D^{(1)}).$$

We assume $D$ is defined with the help of graphs:

$$D_{(\alpha_1, \ldots, \alpha_n)} = \sum_{\Gamma} c_{\Gamma} B_{\Gamma}(\alpha_1 \otimes \cdots \otimes \alpha_n),$$

where the $c_{\Gamma}$ are real. To compute $a(D)^{(1)}$, we need only consider

$$D_{(\alpha_1, \ldots, \alpha_n)}^{(1)} = \sum_{\Gamma \in G^{(1)}} c_{\Gamma} B_{\Gamma}(\alpha_1 \otimes \cdots \otimes \alpha_n),$$

where $G^{(1)}$ denotes the family of 1-graphs, that is, graphs having exactly one leg for each foot.

However, as in [Kontsevich 2003], to define $B_{\Gamma}$ we need to choose a total ordering $O$ on the set $E(\Gamma)$ of edges of $\Gamma$. To be precise, we first choose a labeling on the aerial vertices of $\Gamma$, say $p_1, \ldots, p_n$. Then we put away the arrows starting from $p_1$, from $p_2$, and so on, and finally from $p_n$. We get a total ordering of $E(\Gamma)$ compatible with the ordering $p_1 < p_2 < \cdots < p_n$ in the sense that the arrows starting from $p_i$ precede those starting from $p_{i+1}$.

From now on, we denote by $GO_{n,m}$ the set of oriented graphs $(\Gamma, O)$ with $n$ labeled aerial vertices, $m$ labeled terrestrial vertices and compatible ordering $O$, and by $GO_{n,m}^{(1)}$ the subset of $GO_{n,m}$ formed by the oriented 1-graphs. Our earlier notation $\sum c_{\Gamma} B_{\Gamma}$ actually means

$$\sum_{\Gamma} c_{\Gamma} B_{\Gamma} = \sum_{(\Gamma, O) \in GO_{n,m}} c_{(\Gamma, O)} B_{(\Gamma, O)} \quad \text{and} \quad \sum_{\Gamma \in G^{(1)}} c_{\Gamma} B_{\Gamma} = \sum_{(\Gamma, O) \in GO_{n,m}^{(1)}} c_{(\Gamma, O)} B_{(\Gamma, O)}.$$

### 3.2. A noteworthy property of Kontsevich weights.

**Kontsevich weights.** Let $(\Gamma, O)$ be an oriented graph in $GO_{n,m}^{(1)}$ with aerial vertices $p_1 < \cdots < p_n$. We denote by $k_i$ the number of edges starting from $p_i$, by $U_i$ the ordered set of legs starting from $p_i$, and by $V_i$ the ordered set of aerial edges starting from the same point. Let $\ell_i$ be the number of elements in $V_i$, $U_i$ has $m_i = k_i - \ell_i$ elements. By the definition of $GO_{n,m}^{(1)}$, the number of legs is exactly the number of terrestrial vertices; that is, $m = \sum_{i=1}^n m_i$. 
Given \((\Gamma, O)\), it will be helpful to consider the permutation \(s_O\) defined by

\[
s_O : E(\Gamma) \mapsto V_1 \cup \cdots \cup V_n \cup U_1 \cup \cdots \cup U_n.
\]

After this permutation we get a new (and no longer compatible) ordering \(O'\) on \(E(\Gamma)\) such that all the legs are put at the end, and we can define a permutation \(\tau_O\) of the legs of \((\Gamma, O')\) by putting first the leg ending at \(q_1\), then the leg ending at \(q_2\), and so on, with the the leg ending at \(q_m\) last. We extend the permutation \(\tau_O\) to \(V_1 \cup \cdots \cup V_n \cup U_1 \cup \cdots \cup U_n\) by setting \(\tau_O(v) = v\) for all \(v \in \bigcup V_i\). Finally, note \(\Delta\) the aerial graph obtained from \(\Gamma\) by cutting the legs and the feet and by \(O_\Delta\) the (compatible) ordering on \(\Delta\) induced by \(O\).

Let \(GO_n^{(0)}\) be the set of oriented, purely aerial graphs \((\Delta, O_\Delta)\) with \(n\) vertices.

With these notations, the Kontsevich weight associated with \((\Gamma, O)\) can be written as

\[
w_{(\Gamma, O)} = \frac{1}{k!} e(s_O) e(\tau_O) \int_{C_{\nu, 0}} \bigwedge_{r=1}^{\ell} d\Phi_{\nu, r}^{\Delta} \int_{q_1 < \cdots < q_m \text{ oriented}} \bigwedge_{j=1}^{m} d\Phi_{\bar{p}_j \bar{q}_j},
\]

where \(k! = k_1! \cdots k_n!\), \(|\ell| := \sum \ell_i\), \(V_1 \cup \cdots \cup V_n := \{e_1^\Delta < \cdots < e_n^\Delta\}\) and \(i_j\) stands for the unique index \(i\) such that the leg arriving on \(q_j\) is exactly \(p_iq_j\).

The Kontsevich weight of \((\Delta, O_\Delta)\) is just

\[
w_{(\Delta, O_\Delta)} = \frac{1}{\ell!} \int_{C_{\nu, 0}} \bigwedge_{r=1}^{\ell} d\Phi_{\nu, r}^{\Delta},
\]

\((\ell! = \ell_1! \cdots \ell_n!)\). Thus

\[
w_{(\Gamma, O)} = w_{(\Delta, O_\Delta)} \frac{\ell!}{k!} e(s_O) e(\tau_O) \int_{q_1 < \cdots < q_m \text{ oriented}} \bigwedge_{j=1}^{m} d\Phi_{\bar{p}_j \bar{q}_j}.
\]

The \(S_m\) action on \(GO_{n,m}^{(1)}\). Let \(\sigma\) be an element in the permutation group \(S_m\). With any graph \((\Gamma, O)\) in \(GO_{n,m}^{(1)}\), we associate a new graph \((\sigma(\Gamma), \sigma(O))\). We keep for \(\sigma(\Gamma)\) the vertices of \(\Gamma\). But, if \(E(\Gamma) = \{e_1 < \cdots < e_k\}\), we put \(E(\sigma(\Gamma)) = \{e_1' < \cdots < e_k'\}\), where \(e_i' := e_r\) if \(e_r\) is an aerial edge and \(e_i' := \bar{p}_i \bar{q}_{\sigma(i)}\) if \(e_r = \bar{p}_i \bar{q}_j\) is a leg (see Figure 1). In this way we get a free action of \(S_m\) on \(GO_{n,m}^{(1)}\).

**Lemma 3.1.** For all \(\sigma \in S_m\) and all \((\Gamma, O)\) in \(GO_{n,m}^{(1)}\),

\[
B_{(\sigma(\Gamma), \sigma(O))}(\alpha)(f_1, \ldots, f_m) = B_{(\Gamma, O)}(\alpha)(f_{\sigma(1)}, \ldots, f_{\sigma(m)}) \quad f_i \in C^\infty(\mathbb{R}^d).
\]

**Proof.** Let \(r_j\) be the label of the leg arriving on \(q_j\) in \((\Gamma, O)\). In \((\sigma(\Gamma), \sigma(O))\), this leg has the same label \(r_j\), but it ends at \(q_{\sigma(j)}\). The aerial edges are kept unchanged. The result follows easily. \(\square\)
Lemma 3.2. Let $\sigma$ be in $S_m$ and $(\Gamma, O)$ in $GO_{n,m}^{(1)}$. Then
\[ \varepsilon(s_{\sigma(O)}) = \varepsilon(s_O) \quad \text{and} \quad \varepsilon(\tau_{\sigma(O)}) = \varepsilon(\sigma)\varepsilon(\tau_O). \]

Proof. When building $(\sigma(\Gamma), \sigma(O))$, we get a bijective mapping from $E(\Gamma)$ to $E(\sigma(\Gamma))$, say $\tilde{\sigma}$. In fact, $s_{\sigma(O)} = \tilde{\sigma} \circ s_O \circ \tilde{\sigma}^{-1}$. Thus $\varepsilon(s_{\sigma(O)}) = \varepsilon(s_O)$.

Now let $q_{a_1}, \ldots, q_{a_n}$ be the feet of the legs starting from $p_i$. By definition, $\tau_O$ is the permutation
\[ p_1q_{a_1}, p_1q_{a_2}, \ldots, p_nq_{a_n} \mapsto p_1\tilde{q}_1, \ldots, p_n\tilde{q}_n. \]

We may write
\[ \tau_O^{-1}: (1, \ldots, m) \mapsto (a_1^1, \ldots, a_m^m). \]

By the definition of $(\sigma(\Gamma), \sigma(O))$,
\[ \tau_{\sigma(O)}^{-1}: (1, \ldots, m) \mapsto (\sigma(a_1^1), \ldots, \sigma(a_m^m)). \]

Thus $\tau_{\sigma(O)}^{-1} \circ \tau_O = \sigma$. The result follows. \qed

A noteworthy property.

Proposition 3.3. We keep our notations. In particular, for any $(\Delta, O)$ in $GO_{n,m}^{(1)}$ and any $(\Delta, O)_{\Delta}$ in $GO_{n}^{(0)}$, we denote by $w_{(\Gamma, O)}$ and $w_{(\Delta, O)_{\Delta}}$ the corresponding weights. Then
\[ a\left( \sum_{(\Gamma, O) \in GO_{n,m}^{(1)}} w_{(\Gamma, O)} B_{(\Gamma, O)}(\alpha) \right) = \sum_{(\Delta, O)_{\Delta} \in GO_{n}^{(0)}} w_{(\Delta, O)_{\Delta}} \sum_{m \geq 0} \frac{1}{m!} \sum_{(\Gamma, O) \geq (\Delta, O)_{\Delta}} \frac{\ell!}{k!} \varepsilon(s_O)\varepsilon(\tau_O) B_{(\Gamma, O)}(\alpha). \]

Proof. Skewsymmetrizing and using Lemma 3.1, we get
Lemma 3.2

With the new variables $\sigma$ is the domain $\sigma(O) \supset (\Delta, O)$. Now

$$w(\sigma(O)) = \sum_{\sigma \in S_m} \varepsilon(\sigma) \varepsilon(\tau(O)) \frac{\ell!}{k!} \int_{C_{n,0}} \bigwedge_{r=1}^{\ell} d\Phi_{\Delta, O} \int_{q_1 \cdots q_m \text{ oriented by } dq_1 \cdots dq_m} \bigwedge_{j=1}^m d\Phi_{\sigma(O)}^j,$$

where $i_j$ stands for the unique index $i'$ such that the leg arriving on $q_j$ is exactly $p_j'.q_j$. Now $\bigwedge_{j=1}^m d\Phi_{\sigma(O)}^j = \varepsilon(\sigma) \bigwedge_{j=1}^m d\Phi_{p_j \sigma(O)}$, then, by Lemma 3.2,

$$w(\sigma(O)) = \sum_{\sigma \in S_m} \varepsilon(\sigma) \varepsilon(\tau(O)) \frac{\ell!}{k!} \int_{C_{n,0}} \bigwedge_{r=1}^{\ell} d\Phi_{\Delta, O} \int_{q_1 \cdots q_m \text{ oriented by } dq_1 \cdots dq_m} \bigwedge_{j=1}^m d\Phi_{p_j \sigma(O)}^j,$$

With the new variables $q_j = q_{\sigma(j)}$, we get

$$w(\sigma(O)) = \sum_{\sigma \in S_m} \varepsilon(\sigma) \varepsilon(\tau(O)) \frac{\ell!}{k!} \int_{C_{n,0}} \bigwedge_{r=1}^{\ell} d\Phi_{\Delta, O} \int_{D^\sigma} \bigwedge_{j=1}^m d\Phi_{p_j \sigma(O)}^j,$$

where $D^\sigma$ is the domain $q_1' \cdots q_m'$. Thus

$$a\left( \sum_{\Gamma, O) \in G_{n,m}} w(\Gamma) B(\Gamma, O)(\alpha) \right)$$

$$= \frac{1}{m!} \sum_{\sigma \in S_m} \sum_{\Gamma, O) \in G_{n,m}} w(\Delta, O) \frac{\ell!}{k!} \varepsilon(\tau(O)) \int_{D^\sigma} \bigwedge_{j=1}^m d\Phi_{p_j \sigma(O)}^j B(\Gamma, O)(\alpha)$$

$$= \sum_{(\Delta, O) \in G_{n,m}} \frac{1}{m!} \sum_{(\Gamma, O) \in G_{n,m}} w(\Delta, O) \frac{\ell!}{k!} \varepsilon(\tau(O)) \left( \sum_{\sigma \in S_m} \int_{D^\sigma} \bigwedge_{j=1}^m d\Phi_{p_j \sigma(O)}^j \right) B(\Gamma, O)(\alpha)$$

$$= \sum_{(\Delta, O) \in G_{n,m}} \frac{1}{m!} \sum_{(\Gamma, O) \in G_{n,m}} w(\Delta, O) \frac{\ell!}{k!} \varepsilon(\tau(O)) B(\Gamma, O)(\alpha).$$
3.3. \textit{K-graph formalities}. Consider the explicit Kontsevich formality $\mathcal{U} = \sum_n \mathcal{U}_n$ on $\mathbb{R}^d$. If $(\Gamma, O)$ is an oriented graph with $O$ not compatible, we write, as in [Arnal et al. 2002],

$$B(\Gamma, O) = \varepsilon(\sigma(O, O_0)) B(\Gamma, O_0),$$

where $O_0$ is any compatible orientation on $\Gamma$ and $\sigma(O, O_0)$ stands for the permutation of $E(\Gamma)$ obtained by changing $(\Gamma, O)$ into $(\Gamma, O_0)$. We also put

$$\omega_{\Gamma, O}^f = \frac{k!}{|k|!} \omega_{\Gamma, O} \quad \text{and} \quad w_{\Gamma, O}^f = \int_{C_{n,m}^+} \omega_{\Gamma, O}^f,$$

where $k! = k_1! \ldots k_n!$ and $|k| = \sum k_i$ if $k_i$ is the number of edges emanating from the vertex $p_i$ of $\Gamma$, and $\omega_{\Gamma, O} = d\Phi_{e_1} \wedge \cdots \wedge d\Phi_{e_{|k|}}$ if $E(\Gamma) = \{e_1 < \cdots < e_{|k|}\}$.

We denote by $GO_{n,m}'$ the set of oriented graphs $(\Gamma', O')$, with $O'$ not necessarily compatible. Then

$$\mathcal{U}_n = \sum_{m \geq 0} \sum_{(\Gamma', O') \in GO_{n,m}'^0} w_{(\Gamma', O')}^f B_{(\Gamma', O')}.$$

We write the formality equation for $\mathcal{U}$ as

$$F_n = E_n - d_H(\mathcal{U}_n) = 0.$$

Rewriting the proof of the formality theorem by Kontsevich, one can see that $F_n$ looks like a sum over the faces $F$ of the boundary $\partial C_{n,m}^+$ of $C_{n,m}^+$ (see [Arnal et al. 2002] for details):

$$F_n = \sum_{m \geq 0} \sum_{F \subset \partial C_{n,m}^+} \sum_{(\Gamma', O') \in GO_{n,m}'^0} w_{(\Gamma', O')}^F B_{(\Gamma', O')}.$$

where $w_{(\Gamma', O')}^F$ is the integral over $F$ of the closed $2$-form $\omega_{(\Gamma', O')}^F$.

That $F_n = 0$ then follows directly from the Stokes formula. In particular, we have $\alpha(E_n) = 0$.

Now, we saw that $\alpha(E_n) = \alpha(E_n^{(1)})$. Thus, for a fixed face $F$ of $\partial C_{n,m}^+$, the corresponding term in $\alpha(E_n)$ is a sum over $1$-graphs of the form

$$\alpha \left( \sum_{(\Gamma', O') \in GO_{n,m}'^{(1)}} w_{(\Gamma', O')}^F B_{(\Gamma', O')} \right).$$

Each term of this sum satisfies our relation

$$\alpha \left( \sum_{(\Gamma', O') \in GO_{n,m}'^{(1)}} w_{(\Gamma', O')}^{(\Delta, O_\Delta)} B_{(\Gamma, O')^\Delta} (\alpha) \right) = \sum_{(\Delta, O_\Delta)} w_{(\Delta, O_\Delta)}^{(\Delta, O_\Delta)} \frac{1}{m!} \sum_{GO_{n,m}^0 (\Gamma, O) \supset (\Delta, O_\Delta)} \frac{k!}{k!} \varepsilon(s_0) \varepsilon(t_0) B_{(\Gamma, O)} (\alpha),$$
where \( w_{(\Delta, O_2)}^F = \int_F \omega(\Delta, O_2) \). Let’s prove this:

A face is of either type 1 or type 2 (see [Kontsevich 2003] or [Arnal et al. 2002]). We consider only the faces such that \( w_{(\Gamma_1', O_1')}^F \) can be different from 0.

(i) If the face \( F \) has type 1: Two vertices \( p_i, p_j \) of \( \Gamma_1' \), related by exactly one edge, are collapsing and the face is \( F = C_{\{p_i, p_j\}} \times C_{\{p, p_i, p_j, \ldots, p_n\}} \). We parametrize \( C_{n,m}^+ \) by

\[
\rho = \frac{|p_j - p_i|}{\text{Im} p_i}, \quad p_j' = \frac{p_j - p_i}{|p_j - p_i|} \quad p_i' = \frac{p_i - \text{Re} p_i}{\text{Im} p_i} \quad q_s' = \frac{q_s - \text{Re} p_i}{\text{Im} p_i}.
\]

With the signs computed in [Arnal et al. 2002], we can write

\[
w_{(\Gamma_1', O_1')}^F = -\int_{C_2^+} d\Phi \int_{C_{n-1,m}}^+ \omega_{(\Gamma_2', O_2')},
\]

where \( \Gamma_2' \) is the graph obtained from \( \Gamma_1' \) by gluing together \( p_i \) and \( p_j \) at the point \( p \) and suppressing the edge \( \overrightarrow{p_i p_j} \). This weight \( w_{(\Gamma_1', O_1')}^F \) corresponds to a limit when \( \rho \) tends to zero. In fact, if we put

\[
C_{n,m}^+ (\varepsilon) = C_{n,m}^+ \cap \{(p, q) : \rho = \varepsilon\},
\]

we get

\[
w_{(\Gamma_1', O_1')}^F = \lim_{\varepsilon \to 0} \frac{k!}{k!} \int_{C_{n,m}^+ (\varepsilon)} \omega_{(\Gamma_1', O_1')} := \lim_{\varepsilon \to 0} w_{(\Gamma_1', O_1')}^F (\varepsilon).
\]

This limit vanishes for graphs \( (\Gamma_1', O_1') \) whose vertices \( p_i \) and \( p_j \) are linked by two edges or no edges at all. We can thus also consider these graphs in our sum. Then

\[
a\left( \sum_{(\Gamma_1', O_1') \in GO^{(1)}_{n,m}} w_{(\Gamma_1', O_1')}^F B_{(\Gamma_1', O_1')}(\alpha) \right) = \lim_{\varepsilon \to 0} a\left( \sum_{(\Gamma_1', O_1') \in GO^{(1)}_{n,m}} w_{(\Gamma_1', O_1')}^F (\varepsilon) B_{(\Gamma_1', O_1')}(\alpha) \right).
\]

Passing to compatible orderings, we obtain

\[
a\left( \sum_{(\Gamma_1', O_1') \in GO^{(1)}_{n,m}} w_{(\Gamma_1', O_1')}^F (\varepsilon) B_{(\Gamma_1', O_1')}(\alpha) \right) = \lim_{\varepsilon \to 0} a\left( \sum_{(\Gamma_1', O_1') \in GO^{(1)}_{n,m}} w_{(\Gamma_1', O_1')}(\varepsilon) B_{(\Gamma_1', O_1')}(\alpha) \right).
\]
By Proposition 3.3, we get, as announced,

\[
\alpha \left( \sum_{(\Gamma', O') \in GO_{n,m}^{(1)}} w^F_{(\Gamma', O')} B_{(\Gamma', O')} (\alpha) \right)
\]

\[
= \lim_{\epsilon \to 0} \frac{1}{m!} \sum_{(\Delta, O_{\Delta}) \in GO_{n,m}^{(0)}} w^F_{(\Delta, O_{\Delta})} (\epsilon) \sum_{(\Gamma', O') \in GO_{n,m}^{(1)}} \frac{l!}{k!} \epsilon(s_{\Delta}) \epsilon(\tau_{O'}) B_{(\Gamma', O')} (\alpha)
\]

\[
= \frac{1}{m!} \sum_{(\Delta, O_{\Delta}) \in GO_{n,m}^{(0)}} w^F_{(\Delta, O_{\Delta})} \sum_{(\Gamma', O') \in GO_{n,m}^{(1)}} \frac{l!}{k!} \epsilon(s_{\Delta}) \epsilon(\tau_{O'}) B_{(\Gamma', O')} (\alpha).
\]

(ii) If $F$ has type 2: Since our graphs $(\Gamma', O')$ have exactly one leg for each foot, $F$ is isomorphic to $C_{n_1, m_1}^+ \times C_{n_2, m_2}^+$ with $n_2 > 0$ and $n_1 > 0$. This case corresponds to the subcase 1 of [Arnal et al. 2002]. Suppose that $p_{i_1}, \ldots, p_{i_{n_1}}$ and $q_{\ell+1}, \ldots, q_{\ell+m}$ are collapsing on $q \in \mathbb{R}$. Denote by $p_j$ the first aerial vertex of $\Gamma'$ that is not a $p_{i_j}$, and impose the condition $p_j = \sqrt{-1}$. The other parameters are then fixed and we get a parametrization of our configuration space $C_{n,m}^+$ by variables $a, b, s, t$ (see the notation of [Arnal et al. 2002]). We put $a_{i_1} = q, b = \text{Im} p_{i_1}$, and

\[
p_{i_k}' = \frac{p_{i_k} - q}{b} \quad (2 \leq k \leq n_1), \quad q_{\ell+r}' = \frac{q_{\ell+r} - q}{b} \quad (1 \leq r \leq m_1).
\]

That is, $p_{i_k} = b p_{i_k}' + q b$ and $q_{\ell+r} = q_{\ell+r}' + q b$, and when $b$ tends to zero, the $p_{i_k}$ and the $q_{\ell+r}$ tend to $q$. We finally set

\[
C_{n,m}^+ (\epsilon) = \{(p, q) \in C_{n,m}^+ : b = \epsilon \}.
\]

We get

\[
w^F_{(\Gamma', O')} = \lim_{\epsilon \to 0} \frac{k!}{\epsilon} \int_{C_{n,m}^+ (\epsilon)} \omega_{(\Gamma', O')} = \lim_{\epsilon \to 0} w^F_{(\Gamma', O')} (\epsilon).
\]

If $\Gamma'$ has a bad edge, the weight $w^F_{(\Gamma', O')} (\epsilon)$ vanishes. We can thus consider also these graphs in our sum. Now, a computation similar to that of (i) gives the result.

From now on, for any aerial oriented graph $(\Delta, O_{\Delta})$ in $GO_{n,m}^{(0)}$, denote by $C_{(\Delta, O_{\Delta})}$ the operator $C_{(\Delta, O_{\Delta})} : T_{\text{poly}}^\otimes (\mathbb{R}^d) \to D_{\text{poly}} (\mathbb{R}^d)^{(1)} \simeq T_{\text{poly}} (\mathbb{R}^d)$ defined by

\[
C_{(\Delta, O_{\Delta})} (\alpha_1 \otimes \cdots \otimes \alpha_n) = \sum_{m \geq 0} \frac{1}{m!} \sum_{(\Gamma, O) \in GO_{n,m}^{(1)}} \frac{l!}{k!} \epsilon(s_{\Delta}) \epsilon(\tau_{O}) B_{(\Gamma, O)} (\alpha_1 \otimes \cdots \otimes \alpha_n),
\]

where $\epsilon(s_{\Delta})$ and $\epsilon(\tau_{O})$ have the same meaning as above.
Remark. The definition of $C_{(\Delta, O_\Delta)}$ can be extended naturally to the space $GO_n^{(0)}$ of aerial graphs $(\Delta', O'_\Delta)$ with $O'_\Delta$ not necessarily compatible just by putting

$$C_{(\Delta', O'_\Delta)} = \sum_{m \geq 0} \frac{1}{m!} \sum_{(\Gamma, O) \in GO_n^{(1)}} \frac{\ell!}{k!} \varepsilon(s_{O'}) \varepsilon(\tau O') B_{(\Gamma', O')},$$

We will need to use this extension in Section 5.

Summing up:

**Proposition 3.4.** Consider the explicit Kontsevich formality $c$ on $\mathbb{R}^d$. The formality equation can be read as

$$F_n = E_n - d_H c = 0,$$

and the skewsymmetrization of $E_n$ has the form

$$a \circ E_n = \sum_{m \geq 0} \sum_{\text{F face of } \partial C_{n,m}} \sum_{(\Gamma', O') \in GO_n^{(1)}} w^F_{(\Gamma', O')} B_{(\Gamma', O')},$$

where $w^F_{(\Gamma', O')} = \int_{F \in \partial C_{n,m}} \omega'_{(\Gamma', O')}$. Then, for each face $F$,

$$a \left( \sum_{(\Gamma', O') \in GO_n^{(1)}} w^F_{(\Gamma', O')} B_{(\Gamma', O')} \right) = \sum_{(\Delta, O_\Delta) \in GO_n^{(0)}} w_{(\Delta, O_\Delta)} C_{(\Delta, O_\Delta)}(\alpha).$$

This proposition suggests that we define:

**Definition 3.5.** A mapping $\varphi$ from $T_{poly}(\mathbb{R}^d)^{\otimes n}$ to $D_{poly}(\mathbb{R}^d)^{(1)} \simeq T_{poly}(\mathbb{R}^d)$ is called a $K$-graph mapping if it can be written

$$\varphi = \sum_{(\Delta, O_\Delta) \in GO_n^{(0)}} c_{(\Delta, O_\Delta)} C_{(\Delta, O_\Delta)}$$

with real coefficients $c_{(\Delta, O_\Delta)}$. Such a mapping is homogeneous of degree $s$ if $c_{(\Delta, O_\Delta)} = 0$ for all $\Delta$ such that $\# E(\Delta) + s \neq 2n - 2$.

**Definition 3.6.** A $K$-graph formality $\mathcal{F}$ at order $n$ is a graph formality up to order $n - 1$ such that $\varphi_n = \mathcal{F}_1^{-1} \circ a \circ E_n$ is a $K$-graph mapping.

### 4. Symmetrization

**4.1. Expressions for $\partial$.** If $B$ is an $n$-linear mapping $B : T_{poly}(\mathbb{R}^d)^{\otimes n} \to T_{poly}(\mathbb{R}^d)$, we define $SB$ by setting

$$SB(\alpha_1 \otimes \cdots \otimes \alpha_n) = \frac{1}{n!} \sum_{\sigma \in S_n} e_\sigma(\sigma) B(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)}).$$
and say that $B$ is symmetric if $SB = B$. Any symmetric mapping can be viewed as a map $\varphi : S^n(T_{\text{poly}}(\mathbb{R}^d)) \to T_{\text{poly}}(\mathbb{R}^d)$. With this symmetrization operator $S$, the expression of the Chevalley coboundary operator can be conveniently simplified:

**Proposition 4.1.** Let $\varphi : S^n(T_{\text{poly}}(\mathbb{R}^d)[1]) \to T_{\text{poly}}(\mathbb{R}^d)[1]$ be an $n$-cochain for $\partial$, homogeneous of degree $|\varphi|$. Then we can write

$$\tilde{\partial}\varphi = S(\tilde{\partial}\varphi),$$

where $\tilde{\partial}\varphi$ is given by

$$\tilde{\partial}\varphi(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (n+1)\left(\varphi(\alpha_1 \otimes \cdots \otimes \alpha_n) \bullet \alpha_{n+1} + (-1)^{|\varphi|} \alpha_1 \bullet \varphi(\alpha_2 \otimes \cdots \otimes \alpha_{n+1}) + (-1)^{|\varphi|+1} n\varphi(\alpha_1 \bullet \alpha_2 \otimes \alpha_3 \otimes \cdots \otimes \alpha_{n+1})\right),$$

or else by an expression imitating the Hochschild coboundary operator:

$$\tilde{\partial}\varphi(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (n+1)\left(\varphi(\alpha_1 \otimes \cdots \otimes \alpha_n) \bullet \alpha_{n+1} + (-1)^{|\varphi|+1} \sum_{k=2}^{n+1} (-1)^{\sum_{i=1}^{k-2} |\alpha_i|} \varphi(\alpha_1 \otimes \cdots \otimes \alpha_{k-1} \bullet \alpha_k \otimes \cdots \otimes \alpha_{n+1}) + (-1)^{|\varphi|} \alpha_1 \bullet \varphi(\alpha_2 \otimes \cdots \otimes \alpha_{n+1})\right).$$

**Proof.** By the definition of $\partial$, we have

$$\partial\varphi(\alpha_1 \ldots \alpha_{n+1}) = (1) + (2) + (3),$$

with

(1) = $\sum_{i=1}^{n+1} \varepsilon_\alpha (1 \ldots \hat{i} \ldots n+1, i) \varphi(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1}) \bullet \alpha_i$,

(2) = $\sum_{i=1}^{n+1} (-1)^{|\varphi|} \varepsilon_\alpha (i, 1 \ldots \hat{i} \ldots n+1) \alpha_i \bullet \varphi(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1})$,

(3) = $\sum_{i \neq j} (-1)^{|\varphi|+1} \varepsilon_\alpha (ij, 1 \ldots \hat{i} \ldots \hat{j} \ldots n+1) \varphi(\alpha_i \bullet \alpha_j \ldots \hat{\alpha}_i \hat{\alpha}_j \ldots \alpha_{n+1})$.

Now, put

$$\psi_1(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (n+1)\varphi(\alpha_1 \otimes \cdots \otimes \alpha_n) \bullet \alpha_{n+1},$$

$$\psi_2(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (-1)^{|\varphi|} \varepsilon_\alpha (1 \ldots n+1) \alpha_1 \bullet \varphi(\alpha_2 \otimes \cdots \otimes \alpha_{n+1}),$$

$$\psi_3(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (-1)^{|\varphi|+1} n\varphi(\alpha_1 \bullet \alpha_2 \otimes \cdots \otimes \alpha_{n+1}),$$

$$\psi_3'(\alpha_1 \otimes \cdots \otimes \alpha_{n+1}) = (-1)^{|\varphi|+1} \sum_{k=2}^{n+1} (-1)^{\sum_{i=1}^{k-2} |\alpha_i|} \varphi(\alpha_1 \otimes \cdots \otimes \alpha_{k-1} \bullet \alpha_k \otimes \cdots \otimes \alpha_{n+1})).$$
First

\[
S\psi_1(\alpha_1 \ldots \alpha_{n+1}) = \frac{(n+1)}{(n+1)!} \sum_{\sigma \in S_{n+1}} \epsilon_\sigma(\sigma) \psi(\alpha_{\sigma(1)} \ldots \alpha_{\sigma(n)}) \bullet \alpha_{\sigma(n+1)}
\]

\[
= \frac{(n+1)}{(n+1)!} \sum_{i=1}^{n+1} \sum_{\sigma : \sigma(n+1) = i} \epsilon_\sigma(\sigma) \psi(\alpha_{\sigma(1)} \ldots \alpha_{\sigma(n)}) \bullet \alpha_i
\]

\[
= \frac{(n+1)}{(n+1)!} \sum_{i=1}^{n+1} \sum_{\tau : \tau(i) = i} \epsilon_\sigma(\tau \circ \sigma_i) \psi(\alpha_{\tau(\sigma(1))} \ldots \alpha_{\tau(\sigma(n))}) \bullet \alpha_i.
\]

Here \(\sigma_i\) is the permutation of \(S_{n+1}\) sending \((1, \ldots, n+1)\) to \((1, \ldots, i, \ldots, n+1, i)\).

And, denoting by \(\bar{\tau}\) the restriction of \(\tau\) to \([1, \ldots, i, \ldots, n+1]\), we easily get

\[
S\psi_1(\alpha_1 \ldots \alpha_{n+1})
\]

\[
= \frac{n+1}{(n+1)!} \sum_{i=1}^{n+1} \sum_{t \in S_n} \epsilon_{\alpha_i}[\alpha_i](\bar{\tau}) \epsilon_\tau(\sigma_i) \psi(\alpha_{\bar{\tau}(1)} \ldots \alpha_{\bar{\tau}(n+1)}) \bullet \alpha_i
\]

\[
= \frac{(n+1)}{(n+1)!} n! \sum_{i=1}^{n+1} \epsilon_\tau(1 \ldots \bar{i} \ldots n+1, i) \psi(\alpha_1 \ldots \alpha_i \ldots \alpha_{n+1}) \bullet \alpha_i = (1).
\]

With exactly the same argument, we obtain

\[
S\psi_2(\alpha_1 \ldots \alpha_{n+1}) = (2).
\]

Now,

\[
S\psi_3(\alpha_1 \ldots \alpha_{n+1})
\]

\[
= \sum_{\sigma \in S_{n+1}} \frac{1}{(n+1)!} (-1)^{\left|\sigma\right|} \epsilon_\sigma(\sigma)(n+1)n \psi(\alpha_{\sigma(1)} \bullet \alpha_{\sigma(2)} \otimes \alpha_{\sigma(3)} \otimes \cdots \otimes \alpha_{\sigma(n+1)})
\]

\[
= \sum_{i \neq j} \sum_{\sigma : \sigma(1) = i, \sigma(2) = j} \left( \epsilon_\sigma(\sigma) \frac{1}{(n+1)!} (-1)^{\left|\sigma\right|+1} (n+1)n \psi(\alpha_i \bullet \alpha_j \otimes \alpha_1 \otimes \alpha_{\sigma(3)} \otimes \cdots \otimes \alpha_{\sigma(n+1)}) \right)
\]

\[
= \sum_{i \neq j} \sum_{\tau : \tau(i) = i, \tau(j) = j} \left( \epsilon_\sigma(\sigma) \frac{1}{(n+1)!} \epsilon_\sigma(\sigma_{ij}) (-1)^{\left|\sigma_{ij}\right|+1} (n+1)n \psi(\alpha_i \bullet \alpha_j \otimes \alpha_{\sigma(3)} \otimes \cdots \otimes \alpha_{\sigma(n+1)}) \right),
\]

where \(\sigma_{ij}\) is the permutation of \(S_{n+1}\) sending \((1, \ldots, n+1)\) to \((ij, 1 \ldots \bar{i} \ldots \bar{j} \ldots n+1)\).

Now, if \(\bar{\tau}\) denotes the restriction of \(\tau\) to \([1, \ldots, \bar{i} \ldots \bar{j} \ldots n+1]\), we get

\[
S\psi_3(\alpha_1 \ldots \alpha_{n+1})
\]

\[
= \sum_{i \neq j} \frac{(-1)^{\left|\sigma_{ij}\right|+1}}{(n-1)!} \sum_{\bar{\tau} : \tau(i) = i, \tau(j) = j} \left( \epsilon_\sigma(\sigma_{ij}) \epsilon_\sigma(\bar{\tau}) \psi(\alpha_i \bullet \alpha_j \otimes \alpha_{\bar{\tau}(1)} \otimes \cdots \otimes \alpha_{\bar{\tau}(n+1)}) \right)
\]
Let \( \sigma \) be the permutation \( \sigma(1) \otimes \cdots \otimes \alpha_{(k-2)}(1) \otimes \alpha_{(k-1)} \otimes \cdots \otimes \alpha_{(n+1)} \). Then, we have used the composition \( \sigma^k \) of the permutation \( \sigma \). Finally, we get

\[
S\psi^k_{\sigma}(\alpha_1, \ldots, \alpha_{n+1}) = \sum_{i \neq j} (-1)^{|\psi| + 1} \varepsilon_a(i, j, 1 \ldots \hat{i} \ldots \hat{j} \ldots n+1) \varphi(\alpha_i \cdot \alpha_j \cdot \cdots \alpha_{\hat{i}} \hat{j} \cdots \alpha_{n+1}) = (3).
\]

This ends the proof. \( \square \)
4.2. Symmetrization on graphs. We now want to describe the symmetrization directly on the space of graphs. Since we are mainly interested in $K$-graph formalities, we will restrict ourselves to linear combinations of graphs for which the associated operator is a $K$-graph mapping (see Section 3.3).

The $S_n$ action on $GO_{n,m}$ and $GO_n^{(0)}$. There is a natural action of $S_n$ on $GO_{n,m}$ and $GO_n^{(0)}$, which we now define. Let $\sigma$ be a permutation in $S_n$. Let $(\Gamma, O)$ be in $GO_{n,m}$; for the moment, denote by $P_i$ the set $\text{strt}(p_i)$, ordered by $O$. Let $\sigma\Gamma$ be the permutation of the ordered set $E(\Gamma)$ of edges of $\Gamma$ sending $P_1 \cup \cdots \cup P_n$ to $P_{\sigma(1)} \cup \cdots \cup P_{\sigma(n)}$. We denote by $\varepsilon(\sigma\Gamma)$ the sign of $\sigma\Gamma$ and by $\sigma(\Gamma, O) := (\sigma(\Gamma), \sigma(O))$ the graph with aerial vertices $p_1' = p_{\sigma(1)}, \ldots, p_n' = p_{\sigma(n)}$ oriented by $\sigma\Gamma(E(\Gamma))$ (see Figure 2). We apply the same definition to aerial graphs in $GO_n^{(0)}$. Clearly, $\sigma$ sends $GO_{n,m}$ (and $GO_n^{(0)}$) onto itself.

This $S_n$ action on $GO_{n,m}^{(1)}$ is entirely different from the action of $S_m$ defined in Section 3. But there is an analog of Lemma 3.1:

**Lemma 4.2.** For all $\sigma$ in $S_n$, all $(\Gamma, O)$ in $GO_{n,m}^{(1)}$ and all polyvector fields $\alpha_i$,

$$B(\sigma(\Gamma), \sigma(O))(\alpha_1 \otimes \cdots \otimes \alpha_n) = B(\Gamma, O)(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)}).$$

**Proof.** With our notations,

$$B(\Gamma, O)(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)})(f_1, \ldots, f_m) = \sum_{1 \leq i_1, \ldots, i_m \leq d} \prod_{i=1}^n \partial_{\text{end}(p_i)} \alpha_{\sigma(i)} \prod_{j=1}^m \partial_{\text{end}(q_j)} f_j.$$

Since the permutation $\sigma\Gamma$ does not affect the order inside each $P_i$, we have

$$B(\Gamma, O)(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)})(f_1, \ldots, f_m) = \sum_{1 \leq i_1, \ldots, i_m \leq d} \prod_{i=1}^n \partial_{\text{end}(p_{\sigma(i)})} \alpha_{\sigma'(i)} \prod_{j=1}^m \partial_{\text{end}(q_j)} f_j$$

$$= \sum_{1 \leq i_1, \ldots, i_m \leq d} \prod_{i=1}^n \partial_{\text{end}(p'_i)} \alpha_{i} \prod_{j=1}^m \partial_{\text{end}(q_j)} f_j$$

$$= B(\Gamma, O)(\alpha_1 \otimes \cdots \otimes \alpha_n)(f_1, \ldots, f_m). \quad \Box$$
Symmetrization for $K$-graph mappings.

**Definition 4.3.** Let

$$(\delta, O_\delta) = \sum_{(\Delta, O_\Delta) \in GO_n^0} c_{(\Delta, O_\Delta)}(\Delta, O_\Delta)$$

be a linear combination of aerial graphs with $n$ vertices. We say that $(\delta, O_\delta)$ is symmetric if

$$c_{(\sigma(\Delta), \sigma(O_\Delta))} = \varepsilon(\sigma_\Delta)c_{(\Delta, O_\Delta)}$$

for all $(\Delta, O_\Delta)$ and $\sigma \in S_n$.

**Proposition 4.4.** If $$(\delta, O_\delta) = \sum_{(\Delta, O_\Delta) \in GO_n^0} c_{(\Delta, O_\Delta)}(\Delta, O_\Delta)$$
is symmetric, so is the corresponding $K$-graph mapping

$$C_{(\delta, O_\delta)} = \sum_{(\Delta, O_\Delta) \in GO_n^0} c_{(\Delta, O_\Delta)}C_{(\Delta, O_\Delta)}.$$ 

**Proof.** Let $\sigma$ be in $S_n$ and let $\alpha_1, \ldots, \alpha_n$ be $n$ polyvector fields on $\mathbb{R}^d$. By Lemma 4.2 and using the fact that $\delta$ is symmetric, we have

$$C_{(\delta, O_\delta)}(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)})$$

$$= \sum_{(\Delta, O_\Delta)} c_{(\Delta, O_\Delta)} \frac{1}{m!} \sum_{(\Gamma, O) \supseteq (\Delta, O_\Delta)} \frac{\ell!}{k!} \varepsilon(s_O)\varepsilon(\tau_O) B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n)$$

$$= \sum_{\sigma^{-1}(\Delta, O_\Delta)} c_{(\sigma^{-1}(\Delta), \sigma^{-1}(O_\Delta))} \frac{1}{m!} \sum_{\sigma^{-1}(\Gamma, O) \supseteq \sigma^{-1}(\Delta, O_\Delta)} \frac{\ell!}{k!} \varepsilon(s_{\sigma^{-1}(O)})\varepsilon(\tau_{\sigma^{-1}(O)}) B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n)$$

$$= \sum_{(\Delta, O_\Delta)} \varepsilon_{\Delta}(\sigma_\Delta)c_{(\Delta, O_\Delta)} \frac{1}{m!} \sum_{(\Gamma, O) \supseteq (\Delta, O_\Delta)} \frac{\ell!}{k!} \varepsilon(s_{\sigma^{-1}(O)})\varepsilon(\tau_{\sigma^{-1}(O)}) B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n).$$

Extending $\sigma_\Delta$ to $E(\Gamma)$ in the obvious way, we can write

$$\tau_O \circ s_O = \sigma_\Delta \circ \tau_{\sigma^{-1}(O)} \circ s_{\sigma^{-1}(O)} \circ \sigma_\Gamma^{-1}.$$ 

Thus

$$C_{\delta}(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)})$$

$$= \sum_{(\Delta, O_\Delta)} c_{(\Delta, O_\Delta)} \frac{1}{m!} \sum_{(\Gamma, O) \supseteq (\Delta, O_\Delta)} \varepsilon_{\Gamma}(\sigma_{\Gamma}) \frac{\ell!}{k!} \varepsilon(s_O)\varepsilon(\tau_O) B_{(\Gamma, O)}(\alpha_1 \otimes \cdots \otimes \alpha_n).$$
Since each $\varepsilon_{\Gamma}(\sigma_{\Gamma})$ clearly coincides with the sign $\varepsilon_{\alpha}(\sigma)$ of $\sigma$, we get

$$C_{\delta}(\alpha_{\sigma(1)} \otimes \cdots \otimes \alpha_{\sigma(n)}) = \varepsilon_{\alpha}(\sigma) C_{\delta}(\alpha_{1} \otimes \cdots \otimes \alpha_{n}).$$

This proves the result. \hfill \Box

5. Chevalley cohomology for graphs

We will now prove that, on $K$-graph mappings, the Chevalley coboundary operator can be nicely reduced to an operator acting on purely aerial graphs.

5.1. Purely aerial and compatible oriented graphs. For any $(\Delta, O_{\Delta})$ in $GO_{n}^{(0)}$ with vertices $p_{1} < \cdots < p_{n}$, we still write $\ell_{i} = \#\text{str}_{\Delta}(p_{i})$. We also put $|\Delta| = \sum \ell_{i} = |\ell|$.

Fix two indexes $i \neq j$. We say that an aerial graph $(\Delta', O_{\Delta'})$ in $GO_{n+1}^{(0)}$ (with $O_{\Delta'}$ not necessarily compatible) with vertices $p_{1}' < \cdots < p_{n+1}'$ reduces to $(\Delta, O_{\Delta})$ in the indexes $i, j$ if the two following assertions hold:

(i) The vertices $p_{i}'$ and $p_{j}'$ of $\Delta'$ are linked by only the edge $p_{i}'p_{j}'$.

(ii) the new graph $(\Delta'_{i,j}, O_{\Delta'_{i,j}})$, obtained by gluing together the vertices $p_{i}', p_{j}'$ of $\Delta'$, by suppressing the edge $p_{i}'p_{j}'$ and considering the induced ordering, coincides with $(O, \Delta)$.

We say that $(\Delta', O_{\Delta'})$ reduces properly to $(\Delta, O_{\Delta})$ in the indexes $i, j$ if $(\Delta', O_{\Delta'})$ reduces to $(\Delta, O_{\Delta})$ in the same indexes and in addition

$$\inf (\#\text{str}^{\Delta'}(p_{i}'), \#\text{end}^{\Delta'}(p_{i}'), \#\text{str}^{\Delta'}(p_{j}'), \#\text{end}^{\Delta'}(p_{j}')) > 1.$$ 

In the situations above we write

$$(\Delta', O_{\Delta'}) \to_{i,j} (\Delta, O_{\Delta}) \quad \text{and} \quad (\Delta', O_{\Delta'}) \to_{i,j}^{\text{prop}} (\Delta, O_{\Delta}),$$

respectively. We use the same notation for graphs $(\Gamma, O)$ in $GO_{n, m}^{(1)}$.

\textbf{Definition 5.1.} If $(\Delta, O_{\Delta})$ is an aerial oriented graph in $GO_{n}^{(0)}$, we define the coboundary $\partial(\Delta, O_{\Delta})$ of $(\Delta, O_{\Delta})$ by

$$\partial(\Delta, O_{\Delta}) = (-1)^{|\Delta|+1} \sum_{i \neq j} \sum_{(\Delta', O_{\Delta'}) \to_{i,j}^{\text{prop}} (\Delta, O_{\Delta})} \varepsilon(\Delta', O_{\Delta'}, \Delta, O_{\Delta})(\Delta', O_{\Delta'}).$$

Here $\varepsilon(\Delta', O_{\Delta'}, \Delta, O_{\Delta})$ is the sign of the permutation of $E(\Delta')$, that consists in putting first the edge $p_{i}'p_{j}'$, then the other edges starting from $p_{i}'$ (with the ordering induced by $O_{\Delta'}$), then the edges starting from $p_{j}'$ (also with the induced ordering), and finally all the remaining edges (with the ordering given by $O_{\Delta}$).
We extend \( \partial \) by linearity to all combinations \( (\delta, O_\delta) = \sum_{(\Delta, O_\Delta)} c_{(\Delta, O_\Delta)} (\Delta, O_\Delta) \).

Note that the restriction of \( \partial \) to symmetric combinations of graphs is an operator of cohomology.

More precisely:

**Proposition 5.2.** With the same notations as above and for any symmetric combination of graphs \( (\delta, O_\delta) \), we have

\[
\partial (C(\delta, O_\delta)) = C(\delta, O_\delta).
\]

**Proof.** First, \( C(\Delta, O_\Delta) \) is a linear combination of \( m \)-differential operators \( B_\Gamma(\alpha) \), for certain \( k_i \)-vector fields \( \alpha_i \):

\[
m - 2 = |B_\Gamma(\alpha)\alpha_1 \otimes \cdots \otimes \alpha_n| = \sum_{i=1}^n |\alpha_i| + |B_\Gamma(\alpha)| = \sum_{i=1}^n k_i - 2n + |B_\Gamma(\alpha)|,
\]

where \( | \cdot | \) stands for the degree in \( T_{\text{poly}}(\mathbb{R}^d)[1] \) and \( D_{\text{poly}}(\mathbb{R}^d)[1] \). Now, since the graphs \( (\Gamma, O) \) occurring in \( C(\Delta, O_\Delta) \) are 1-graphs, we have \( k_i = \ell_i + m_i \) for each \( i \) and \( m = \sum_{i=1}^n m_i \). Thus

\[
|B_\Gamma(\alpha)| = \sum_{i=1}^n \ell_i = |\Delta| \mod 2.
\]

Now, by the definition of \( \partial \) on operators,

\[
\partial C(\Delta, O_\Delta)(\alpha_1 \ldots \alpha_{n+1})
\]

\[
= \sum_{j=1}^{n+1} \varepsilon(\alpha_1 \ldots j \ldots n+1, j) C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_j \ldots \alpha_{n+1}) \cdot \alpha_j
\]

\[
+ \sum_{i=1}^{n+1} (-1)^{|\Delta|/|\alpha|} \varepsilon(\alpha, 1 \ldots \hat{i} \ldots n+1) \alpha_i \cdot C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1})
\]

\[
+ \sum_{i \neq j} (-1)^{|\Delta|+1} \varepsilon(\alpha, i \ldots j \ldots n+1) C(\Delta, O_\Delta)(\alpha_i \cdot \alpha_j \ldots \alpha_{n+1})
\]

\[
= (i) + (ii) + (iii).
\]

We first consider the term (iii). We have

\[
C(\Delta, O_\Delta)(\alpha_i \cdot \alpha_j \ldots \hat{\alpha}_j \alpha_{i} \ldots \alpha_{n+1})
\]

\[
= \sum_{m \geq 0} \frac{1}{m!} \sum_{GO_{\alpha,m} \supset (\Gamma, O) \supset (\Delta, O_\Delta)} \frac{\ell!}{k!} \varepsilon(s_O) \varepsilon(\tau_O) B_{(\Gamma, O)}(\alpha_i \cdot \alpha_j \ldots \hat{\alpha}_j \alpha_i \ldots \alpha_{n+1}).
\]
Now, we can write (see [Arnal et al. 2002] for details)

\[ B_{(\Gamma, O)}(\alpha_i \bullet \alpha_j \bullet \alpha_1 \ldots \alpha_{n+1}) = \sum_{(\Gamma', O') \rightarrow (\Gamma, O)} (-1)^{\ell_{\Gamma'}} B_{(\Gamma', O')}(\alpha_1 \ldots \alpha_{n+1}), \]

where \( \ell_{\Gamma'} \) denotes the position of the edge \( \overrightarrow{p_i p_j} \) in \( \Gamma' \), and the sign \((-1)^{\ell_{\Gamma'}}\) comes directly from the definition of \( \bullet \).

Next consider a graph \((\Gamma', O')\) that reduces to \((\Gamma, O)\) in the indexes \(i, j\). We permute the edges as follows: we put first the edge \( p_i p_j \), then the other edges starting from \( p_i' \), then the edges starting from \( p_j' \), and finally we put all the legs at the end in order of their feet. This gives a sign that can be written as

\[ \varepsilon_a(i j, 1 \ldots \hat{i} \ldots n+1) (-1)^{\ell_{\Gamma'}} \varepsilon(s_O) \varepsilon(\tau_O). \]

Starting from \((\Gamma', O')\), one can also place the legs at the end in order of their feet, preceded by the aerial edges starting from \( p_i' \) and those starting from \( p_j' \), and then by the aerial edge \( \overrightarrow{p_i p_j} \) at the first position. If we denote by \( \Delta' \) the aerial part of \( \Gamma' \) and by \( \ell_{\Delta'} \) the position of the edge \( \overrightarrow{p_i p_j} \) in \( \Delta' \), the resulting sign is

\[ \varepsilon(s_O) \varepsilon(\tau_O) \varepsilon(\Delta', \Delta)(-1)^{\ell_{\Delta'}}. \]

These two permutations of the edges of \( \Gamma' \) obviously coincide; thus

\[ \varepsilon_a(i j, 1 \ldots \hat{i} \ldots n+1) (-1)^{\ell_{\Gamma'}} \varepsilon(s_O) \varepsilon(\tau_O) = \varepsilon(s_O) \varepsilon(\tau_O) \varepsilon(\Delta', \Delta)(-1)^{\ell_{\Delta'}}. \]

It follows that

\[ C_{(\Delta, O_{\Delta})}(\alpha_i \bullet \alpha_j \ldots \overrightarrow{\alpha_i \alpha_j} \ldots \alpha_{n+1}) \]

\[ = \sum_{m \geq 0} \frac{1}{m!} \left( \sum_{(\Gamma, O) \in GO_{n, m}^{(1)}} \sum_{(\Gamma', O') \rightarrow (\Delta, O_{\Delta})} \varepsilon(\Delta', \Delta) \varepsilon(\tau_O) B_{(\Gamma', O')}(\alpha_1 \ldots \alpha_{n+1}) \right) \]

\[ = \varepsilon_a(i j, 1 \ldots n+1) \sum_{m \geq 0} \frac{1}{m!} \left( \sum_{(\Delta', O_{\Delta}) \rightarrow (\Delta, O_{\Delta})} (-1)^{\ell_{\Delta'} - 1} \varepsilon(\Delta', \Delta) \varepsilon(\tau_O) B_{(\Gamma', O')}(\alpha_1 \ldots \alpha_{n+1}) \right) \]

\[ = \varepsilon_a(i j, 1 \ldots n+1) \sum_{(\Delta', O_{\Delta}) \rightarrow (\Delta, O_{\Delta})} (-1)^{\ell_{\Delta'} - 1} \varepsilon(\Delta', \Delta) C_{(\Delta', O_{\Delta})}(\alpha_1 \ldots \alpha_{n+1}). \]
Finally,
\[(iii) = (-1)^{|\Delta|+1} \sum_{(\Delta', O_{\Delta'}) \to i, j (\Delta, O_\Delta)} (-1)^{\ell_{\Delta'} - 1} \varepsilon(\Delta', \Delta) C_{(\Delta', O_{\Delta'})}(\alpha_1 \ldots \alpha_{n+1})} = (-1)^{|\Delta|+1} \sum_{(\Delta', O_{\Delta'}) \to i, j (\Delta, O_\Delta)} \varepsilon(\Delta', O_{\Delta'}, \Delta, O_\Delta) C_{(\Delta', O_{\Delta'})}(\alpha_1 \ldots \alpha_{n+1}).\]

Now let \((\delta, O_\delta) = \sum c(\Delta, O_\Delta) (\Delta, O_\Delta)\) be a symmetric combination of graphs and put
\[C(\delta, O_\delta) = (i)_\delta + (ii)_\delta + (iii)_\delta.\]

We have to prove that \(-(i)_\delta + (ii)_\delta\) coincides with the nonproper terms of \((iii)_\delta\), that is, with
\[\sum_{(\Delta, O_\Delta)} c(\Delta, O_\Delta) (-1)^{|\Delta|+1} \sum_{i \neq j (\Delta', O_{\Delta'}) \to i, j (\Delta, O_\Delta)} (-1)^{\ell_{\Delta'} - 1} \varepsilon(\Delta', O_{\Delta'})(\Delta', O_{\Delta'}).\]

Consider first the term
\[(ii)_\delta = \sum_{(\Delta, O_\Delta)} c(\Delta, O_\Delta) \sum_{i=1}^n (-1)^{|\alpha_i|} \varepsilon_{\alpha}(i, 1 \ldots n+1) \alpha_i \cdot C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1}).\]

We identify \(C(\Delta, O_\Delta)(\alpha)\) with a polyvector field, and put
\[C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1}) = \left(C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1})\right)^{r_1 \ldots r_m} \partial_1 \wedge \ldots \wedge \partial_m.\]

Thus
\[\alpha_i \cdot C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i \ldots \alpha_{n+1}) = \sum_{j \neq i} \sum_{l \leq k_i} (-1)^{1 - \ell_1} \alpha_i \hat{\alpha}_i \ldots \hat{\alpha}_{k_i+1} (C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_j(a_j) \ldots \hat{\alpha}_i \ldots \alpha_{n+1}))^{r_1 \ldots r_m} \partial_1 \wedge \ldots \wedge \partial_{k_i-1} \wedge \partial_j \wedge \ldots \wedge \partial_m.\]

Let \(\sigma\) be the permutation \((j_1 \ldots \hat{j}_i \ldots n+1)\) and \((\Delta^\sigma, O_{\Delta^\sigma})\) be the aerial graph obtained by relabeling the vertices of \(\Delta\) in the ordering given by \(\sigma\). Then
\[C(\Delta, O_\Delta)(\alpha_1 \ldots \hat{\alpha}_i(a_j) \ldots \hat{\alpha}_j \ldots \alpha_{n+1}) = C(\Delta^\sigma, O_{\Delta^\sigma})(\partial_j a_j a_1 \ldots \hat{\alpha}_j \hat{\alpha}_j \ldots \alpha_{n+1}).\]

But \((\delta, O_\delta)\) is symmetric; thus
\[c(\Delta^\sigma, O_{\Delta^\sigma}) = c(\Delta, O_\Delta) \varepsilon_{\alpha}(j, 1 \ldots \hat{j}_i \ldots n+1).\]

Hence,
\[(ii)_\delta = \sum_{(\Delta, O_\Delta)} \sum_{i \neq j} (-1)^{|\alpha_i|} \varepsilon_{\alpha}(i j 1 \ldots n+1) c(\Delta, O_\Delta) \sum_{\ell \leq k_i} (-1)^{1 - \ell} \alpha_i^{l_1 \ldots l_{k_i+1}} (C(\Delta, O_\Delta)(\partial_j a_j a_1 \ldots \hat{\alpha}_j \hat{\alpha}_j \ldots \alpha_{n+1}))^{r_1 \ldots r_m} \partial_1 \wedge \ldots \wedge \partial_{k_i-1} \wedge \partial_j \wedge \ldots \wedge \partial_m.\]
It is now easy to see that \(-\text{(ii)}\) coincides with certain nonproper terms of \((\text{iii})_\delta\) — more precisely, with those corresponding to the graphs \(\Delta'\) with 
\[
(\Delta', O_{\Delta'}) \rightarrow i, j \ (\Delta, O_{\Delta}) \quad \text{and} \quad \left(\# \text{str}^\Delta(p'_i) + \# \text{end}^\Delta(p'_j)\right) = 1.
\]
(In this case, \(\ell_{\Delta'} = 1\).) In the same way, one can check that \(-\text{(i)}\) coincides with the remaining nonproper terms of \((\text{iii})_\delta\), that is, with the nonproper terms corresponding to the case 
\[
(\Delta', O_{\Delta'}) \rightarrow i, j \ (\Delta, O_{\Delta}) \quad \text{and} \quad \left(\# \text{str}^\Delta(p'_i) + \# \text{end}^\Delta(p'_j)\right) = 1.
\]
The result follows. \(\Box\)

5.2. Purely aerial and nonoriented graphs. We say that a graph is nonoriented if there is an ordering only on the aerial vertices but no ordering on the edges of the graph. We are now interested in translating our cohomology on nonoriented graphs.

Let \(\Delta\) be an aerial nonoriented graph with \(n\) vertices \(p_1 < \cdots < p_n\). We still write \(\ell_i = \text{str}^\Delta(p_i)\) and \(\ell! = \ell_1! \cdots \ell_n!\). We order the edges of \(\Delta\) lexicographically:
\[
\vec{a}b \leq \vec{a'}b' \quad \text{if and only if} \quad (a = a' \text{ and } a < b') \text{ or } (a < a').
\]
This yields a compatible ordering on \(\Delta\), called the standard ordering. We denote by \((\Delta, O_{\Delta})\) the resulting oriented graph.

Now put
\[
\Delta = \frac{1}{\ell!} \sum_{O_{\Delta}: (\Delta, O_{\Delta}) \in \text{GO}^0_\Delta} \varepsilon(\sigma_{O_{\Delta}^{\text{std}}, O_{\Delta}})(\Delta, O_{\Delta}).
\]
By the definition of \(\partial\) on compatible oriented graphs, we have:
\[
\partial \Delta = \frac{1}{\ell!} \left( \sum_{O_{\Delta}: (\Delta, O_{\Delta}) \in \text{GO}^0_\Delta} \varepsilon(\sigma_{O_{\Delta}^{\text{std}}, O_{\Delta}})(-1)^{|\Delta|+1} \sum_{i \not= j} \sum_{(\Delta', O_{\Delta'}) \rightarrow i^\text{pop}_{ij}(\Delta, O_{\Delta})} \varepsilon(\Delta', O_{\Delta'}, \Delta, O_{\Delta})(\Delta', O_{\Delta'}) \right).
\]
Note that the sign
\[
\tilde{\varepsilon}(\Delta, \Delta') := \varepsilon(O_{\Delta}^{\text{std}}, O_{\Delta}) \varepsilon(\Delta', O_{\Delta'}, \Delta, O_{\Delta}) \varepsilon(O_{\Delta'}^{\text{std}}, O_{\Delta'})
\]
does not depend on \(O_{\Delta}\) or \(O_{\Delta'}\). This yields a very simple expression for the coboundary \(\partial \Delta\) of \(\Delta\):
\[
\partial \Delta = \frac{1}{\ell!} \sum_{i \not= j} \sum_{\Delta' \supset \Delta} \tilde{\varepsilon}(\Delta', \Delta) \Delta'.
\]
We extend \(\partial\) to linear combination of graphs \(\delta = \sum_{\Delta} c_{\Delta} \Delta\).
Now, if $\Delta$ is a nonoriented graph with vertices $p_1 < \cdots < p_n$ and if $\sigma$ is a permutation in $S_n$, we denote by $\sigma(\Delta)$ the nonoriented graph with vertices $p_{\sigma(1)} < \cdots < p_{\sigma(n)}$. A linear combination $\delta = \sum_{\Delta} c_{\Delta} \Delta$ of nonoriented graphs with $n$ labeled vertices is said to be symmetric if for any $\sigma$ in $S_n$, we have $c_{\Delta} = c_{\sigma(\Delta)}$. Our operator $\partial$ restricted to symmetric $\delta$ is clearly a cohomology operator.

More precisely, for an aerial nonoriented graph $\Delta$, let

$$C_{\Delta} = \frac{1}{\ell!} \sum_{O_{\Delta}(\Delta, \sigma_{\Delta}) \in GO_n^{(0)}} \varepsilon(\sigma_{\Delta}) \varepsilon(\sigma_{\Delta}) C_{\Delta}(\sigma_{\Delta}).$$

Extend this definition by linearity to all linear combinations. Then, by computations similar to those we did before for oriented graphs, we can prove:

**Proposition 5.3.** For any symmetric combination $\delta = \sum_{\Delta} c_{\Delta} \Delta$ of graphs with $n$ labeled vertices, we have

$$\partial(\delta) = C_{\partial(\delta)}.$$

5.3. Examples. Let $\Delta_1$ be the graph with only one vertex $p_1$. Let $\alpha_1$ be a $k_1$-vector field. Then

$$C_{\Delta_1}(\alpha_1) = \frac{1}{(k_1)!^2} \sum_{G_{\Delta_1}(1) \supset (\Gamma, O) \supset \Delta_1} \varepsilon(\sigma_{\Delta_1}) \varepsilon(\sigma_{\Delta_1}) B_{(\Gamma, O)}(\alpha_1).$$

There is only one graph occurring in this sum, namely the graph $\Gamma$ with one aerial vertex $p_1$, $k_1$ terrestrial vertices $q_1, \ldots, q_{k_1}$ and $k_1$ edges $p_1q_{(1)}, \ldots, p_1q_{(k_1)}$. For any $\sigma$ in $S_{k_1}$, denote by $(\Gamma, O^*_{\sigma})$ the graph $\Gamma$ endowed with the ordering given by $\overrightarrow{p_1q_{(1)}} \cdots \overrightarrow{p_1q_{(k_1)}}$. Clearly,

$$C_{\Delta_1}(\alpha_1) = \frac{1}{(k_1)!^2} \sum_{\sigma \in S_{k_1}} \varepsilon(\sigma_{\Delta_1}) B_{(\Gamma, O^*_{\sigma})}(\alpha_1) = B_{(\Gamma, O^*)}(\alpha_1) \simeq \alpha_1,$$

and $C_{\Delta_1}$ just corresponds to the identity mapping.

Now let $\Delta_2$ be the aerial graph with two vertices $p_1 < p_2$ and one edge $p_1p_2$. Let $\alpha_1$ be a $k_1$-vector field and $\alpha_2$ a $k_2$-vector field. Then

$$C_{\Delta_2}(\alpha_1 \otimes \alpha_2) = \frac{1}{(k_1 + k_2 - 1)!} \sum_{(\Gamma, O) \supset \Delta_2} \frac{1}{k_1! k_2!} \varepsilon(s_{\sigma_{\Delta}}) \varepsilon(\sigma_{\Delta}) B_{(\Gamma, O)}(\alpha_1 \otimes \alpha_2).$$

There are exactly $(k_1 + k_2 - 1)!/(k_1! k_2!)$ graphs $\Gamma$ containing $\Delta_2$ and having exactly $(k_1 - 1)$ legs starting from $p_1$ and $k_2$ legs starting from $p_2$. For each of them, we choose a compatible ordering. There are $k_1! k_2!$ possibilities to do it. Thus, there are exactly $k_1(k_1 + k_2 - 1)!$ compatible oriented graphs $(\Gamma, O)$ occurring in $C_{\Delta_2}$. For each of these graphs, $\varepsilon(s_{\sigma_{\Delta}})$ corresponds to the permutation of $S_{k_1}$ that consists in
putting the aerial edge of \((\Gamma, O)\) at the first position and \(\varepsilon(\tau_O)\) corresponds to the permutation of \(S_{k_1+k_2-1}\) that consists in putting the legs in the order of the feet. There is thus \(k_1(k_1 + k_2 - 1)!\) terms in \(C_{\Delta_2}\), each of which looks like

\[
\frac{1}{(k_1 + k_2 - 1)!k_1!k_2!} \varepsilon(s_O) \varepsilon(\tau_O) B(\Gamma, O) = \frac{1}{(k_1 + k_2 - 1)!k_1!k_2!} (-1)^{\ell-1} \varepsilon(\sigma) \alpha_i \sigma(1) \cdots \sigma(\ell-1) s_i \sigma(\ell) \cdots \sigma(k_1-1).
\]

Thus

\[
C_{\Delta_2}(\alpha_1 \otimes \alpha_2) = \varepsilon(0) (\alpha_1 \bullet \alpha_2) \simeq \alpha_1 \bullet \alpha_2.
\]

Now consider the aerial graph \(\Delta_2^-\) with two vertices \(p_1 < p_2\) and one edge \(\overrightarrow{p_2 p_1}\).

In the same way as above, one can see that

\[
C_{\Delta_2^-}(\alpha_1 \otimes \alpha_2) = \varepsilon(0) (\alpha_1 \bullet \alpha_2) \simeq \alpha_1 \bullet \alpha_2.
\]

In other words, \(C_{\Delta_2+\Delta_2^-}\) coincides with \(Q_2\).

The identity map \(\text{Id}\) and \(Q_2\) are thus easy examples of \(K\)-graph mappings, and the fact that \(Q_2\) is the Chevalley coboundary of \(\text{Id}\) can be checked directly on the graphs. Indeed, we have with our notations:

\[
\partial \Delta_1 = \bar{\varepsilon}((\Delta_2, \Delta_1) \Delta_2 + \bar{\varepsilon}(\Delta_2^-, \Delta_1) \Delta_2^-) = \Delta_2 + \Delta_2^-.
\]

Hence,

\[
Q_2 = C_{\Delta_2+\Delta_2^-} = \partial C_{\Delta_1} = \partial \text{Id}.
\]

6. Triviality of the cohomology for small \(n\)

Our first example proves that the first cohomology group \(H^1\) is trivial, since, for \(n = 1\), there is only one purely aerial graph, namely \(\Delta_1\).

Now suppose \(n = 2\). There is one graph \(\Delta\) with two vertices and with degree 0 \(|\Delta| = 0\), the nonconnected symmetric graph denoted \(\Delta_1 \times \Delta_1\) without any edges. Its coboundary does not vanish; in the obvious notation, we have

\[
\partial(\Delta_1 \times \Delta_1) = S((\Delta_2^+ + \Delta_2^-) \times \Delta_1 + \Delta_1 \times (\Delta_2^+ + \Delta_2^-)) \neq 0.
\]

In degree 1 \(|\Delta| = 1\), there is only one symmetrized graph, \(\Delta_2^+ + \Delta_2^-\). Our second example shows that this graph is a coboundary.

Finally, there is no graph with degree larger than 1; indeed, the number of edges for a graph with 2 vertices is at most 2, but there is only one graph \(\Delta\) with \(|\Delta| = 2\), the graph \(\Delta_{2,2}\) given by

\[
p_1 \overset{\text{edge}}{\longrightarrow} p_2
\]
But the symmetrization of this graph is $\Delta_{2,2} - \Delta_{2,2} = 0$. Thus the second cohomology group $H^2$ vanishes.

It is possible to prove with elementary arguments that $H^3 = 0$ too. For that, we consider the different cases, $|\Delta| = 0, \ldots, 6$, then we define the order of a graph in the following way:

We define the order $o_i$ of a vertex $p_i$ as the pair $(\ell_i, r_i)$ of number $\ell_i$ of edges starting from $p_i$ and the number $r_i$ of edges ending at $p_i$, we shall say that $o = (\ell, r)$ is smaller than $o' = (\ell', r')$ and note $o < o'$ if and only if $\ell + r < \ell' + r'$ or $\ell + r = \ell' + r'$ and $\ell < \ell'$.

We define then the order $o(\Delta)$ of a graph $\Delta$ as $o(\Delta) = (o_1, \ldots, o_n)$ if $\Delta$ has $n$ vertices. The order $o(\delta)$ of a linear combination $\delta = \sum c_\Delta \Delta$ of graphs is the maximum of $o(\Delta)$ for $c_\Delta \neq 0$ for the lexicographic ordering. We define the symbol of $\delta$ by

$$\text{symb}\ \delta = \sum_{o(\Delta) = o(\delta)} c_\Delta C_\Delta.$$ 

**Case 1:** $|\Delta| = 0$. There is only one graph, disconnected and symmetric: the graph $\Delta_1 \times \Delta_1 \times \Delta_1$. It is not a cocycle since

$$\partial(\Delta_1 \times \Delta_1 \times \Delta_1) = \delta((\Delta_2^+ + \Delta_2^-) \times \Delta_1 \times \Delta_1) \neq 0.$$ 

**Case 2:** $|\Delta| = 1$. There is, up to the ordering of vertices, only one symmetrized, disconnected graph: $\delta = S(\Delta_2^+ \times \Delta_1)$. This graph is a coboundary:

$$\partial(\Delta_1 \times \Delta_1) = \frac{1}{3} S((\Delta_2^+ + \Delta_2^-) \times \Delta_1) = \frac{2}{3} \delta.$$ 

**Case 3:** $|\Delta| = 2$. There is, up to the ordering of vertices, a disconnected graph $\Delta_{2,2} \times \Delta_1$ and three connected graphs, listed below. (We choose the ordering of vertices that maximizes the order, and for a given order maximizes, for the lexicographic ordering, the set $E(\Delta)$ of edges of graphs $\Delta$.)

$$\Delta_{3,2,1} \quad \text{with} \quad E(\Delta_{3,2,1}) = \{\overrightarrow{p_1 p_2}, \overrightarrow{p_1 p_3}\},$$

$$\Delta_{3,2,2} \quad \text{with} \quad E(\Delta_{3,2,2}) = \{\overrightarrow{p_2 p_1}, \overrightarrow{p_3 p_1}\},$$

$$\Delta_{3,2,3} \quad \text{with} \quad E(\Delta_{3,2,3}) = \{\overrightarrow{p_2 p_1}, \overrightarrow{p_3 p_1}\}.$$ 

After symmetrization, we get

$$S(\Delta_{2,2} \times \Delta_1) = 0, \ S(\Delta_{3,2,1})) = S(\Delta_{3,2,3}) = 0$$

and

$$\text{symb} \ S(\Delta_{3,2,2}) = \delta_{\Delta_{3,2,2}}, \quad o(S(\Delta_{3,2,2})) = ((1, 1), (1, 0), (0, 1)).$$

When we compute $\partial(S(D))$, we have to consider the blow-up of each vertex of each graph in $S(\Delta)$. If the vertex $p$ has order $o = (\ell, r)$, we get a few graphs with two vertices $p'$ and $p''$ at the place of $p$; these vertices have order $o' = (\ell', r')$,
Then $\partial$ is still a one-to-one mapping on that space of graphs.

Case 4: $|\Delta| = 3$. From now on, all our graphs are connected. Repeating the argument of the preceding case, we get the following results:

They are, up to a permutation of vertices, four graphs:

- $\Delta_{3,3,1}$ with $E(\Delta_{3,3,1}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}\}$,
- $\Delta_{3,3,2}$ with $E(\Delta_{3,3,2}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_1}\}$,
- $\Delta_{3,3,3}$ with $E(\Delta_{3,3,3}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_3}\}$,
- $\Delta_{3,3,4}$ with $E(\Delta_{3,3,4}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_2p_3}, \overrightarrow{p_3p_1}\}$.

Their symmetrizations do not vanish:

- $o(S(\Delta_{3,3,1})) = (2, 1), (1, 1), (0, 1))$,
- $o(\partial(S(\Delta_{3,3,1}))) = ((3, 0), (1, 1), (0, 2), (0, 1))$,
- $o(S(\Delta_{3,3,2})) = ((1, 2), (1, 1), (1, 0))$,
- $o(\partial(S(\Delta_{3,3,2}))) = ((2, 1), (1, 1), (0, 2), (0, 1))$,
- $o(S(\Delta_{3,3,3})) = ((2, 0), (1, 1), (1, 0))$,
- $o(\partial(S(\Delta_{3,3,3}))) = ((2, 0), (2, 0), (0, 2), (0, 2))$,
- $o(S(\Delta_{3,3,4})) = ((1, 1), (1, 1), (1, 1))$,
- $o(\partial(S(\Delta_{3,3,4}))) = ((2, 0), (1, 1), (1, 1), (0, 2))$.

Then $\partial$ is still a one-to-one mapping on that space of graphs.

Case 5: $|\Delta| = 4$. They are, up to a permutation of vertices, four graphs:
$\Delta_{3,4,1}$ with $E(\Delta_{3,4,1}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_1}\}$.

$\Delta_{3,4,2}$ with $E(\Delta_{3,4,2}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_2}\}$.

$\Delta_{3,4,3}$ with $E(\Delta_{3,4,3}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_2}\}$.

$\Delta_{3,4,4}$ with $E(\Delta_{3,4,4}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_1}, \overrightarrow{p_3p_2}\}$.

Their symmetrizations do not vanish:

\[
o(\Delta_{3,4,1}) = (2, 2), (1, 1), (1, 1)\),

\[
o(\partial(S(\Delta_{3,4,1}))) = ((3, 1), (1, 1), (1, 1), (0, 2))\),

\[
o(\Delta_{3,4,2}) = (2, 1), (2, 1), (0, 2)\),

\[
o(\partial(S(\Delta_{3,4,2}))) = ((3, 0), (2, 1), (0, 2), (0, 2))\),

\[
o(\Delta_{3,4,3}) = (2, 1), (1, 2), (1, 1)\),

\[
o(\partial(S(\Delta_{3,4,3}))) = ((3, 0), (1, 2), (1, 1), (0, 2))\),

\[
o(\Delta_{3,4,4}) = (1, 2), (1, 2), (0)\),

\[
o(\partial(S(\Delta_{3,4,4}))) = ((2, 1), (1, 2), (2, 0))\).

Then $\partial$ is still a one-to-one mapping on that space of graphs.

Case 6: $|\Delta| = 5$. Up to a permutation of vertices, this space contains only one graph:

$\Delta_{3,5,1}$ with $E(\Delta_{3,5,1}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_2}\}$.

Its symmetrization does not vanish,

\[
o(S(\Delta_{3,5,1})) = (2, 2), (2, 1), (1, 2)\),

\[
o(\partial(S(\Delta_{3,5,1}))) = ((3, 1), (2, 1), (1, 2), (0, 2))\).

Then $\partial$ is still a one-to-one mapping on that space of graphs.

Case 7: $|\Delta| = 6$. In this last case, there is only one graph:

$\Delta_{3,6,1}$ with $E(\Delta_{3,6,1}) = \{\overrightarrow{p_1p_2}, \overrightarrow{p_1p_3}, \overrightarrow{p_2p_1}, \overrightarrow{p_3p_2}\}$.

But its symmetrization does vanish.

This proves:

**Proposition 6.1.** The three first spaces $H^1$, $H^2$ and $H^3$ of the Chevalley cohomology for graphs vanish.
7. Canonical cocycles for the linear case

We first recall the construction of the relevant cocycles for the cohomology of the Lie algebra of vector fields $\mathfrak{X}(\mathbb{R}^d)$ associated to the Lie derivative of smooth functions; see for instance [De Wilde and Lecomte 1983] for an explicit presentation of this cohomology.

A basis of the Lie algebra $\wedge^\text{inv} (\mathfrak{gl}(d, \mathbb{R}))$ of multilinear, skewsymmetric, invariant forms on $\mathfrak{gl}(d, \mathbb{R})$ is given by

$$\zeta^{(j_1)} \wedge \cdots \wedge \zeta^{(j_q)}$$

with $j_k$ odd and $j_1 < j_2 < \cdots < j_q < 2d$,

where the $\zeta^{(j)}$ are the mappings

$$\zeta^{(j)}(A_1, \ldots, A_j) = a(\text{Tr}(A_1 \ldots A_j)).$$

Then, for each odd $n$, the linear form $\theta$ defined on $\wedge^n \mathfrak{X}(\mathbb{R}^d)$ by

$$\theta(\xi_1, \xi_2, \ldots, \xi_n) = \zeta^{(n)}(\text{Jac}(\xi_1), \ldots, \text{Jac}(\xi_n))$$

is a cocycle for the coboundary operator associated to the Lie derivative:

$$d\theta(\xi_0, \ldots, \xi_n) = \sum_{i=0}^{n} (-1)^i \mathcal{L}_{\xi_i} \theta(\xi_0, \ldots, \hat{\xi}_i, \ldots, \xi_n)$$

$$+ \frac{1}{2} \sum_{i \neq j} (-1)^{i+j} \theta([\xi_i, \xi_j], \xi_0, \ldots, \hat{\xi}_i \hat{\xi}_j, \ldots, \xi_n).$$

This cocycle is not a coboundary; see [De Wilde and Lecomte 1983].

Let $\Psi$ be an $n$-cochain on $T_{\text{poly}}(\mathbb{R}^d)$ with values in the space $T_{\text{poly}}(\mathbb{R}^d)^{-1}$ (that is, in $C^\infty(\mathbb{R}^d)$), and let $\psi$ be its restriction to $\mathfrak{X}(\mathbb{R}^d)$. Then the restriction of $\partial \Psi$ to $\mathfrak{X}(\mathbb{R}^d)$ is exactly $d\psi$.

For instance, we consider the “wheel without an axis”, the graph $\Delta$ of this form:
Denote by $\delta$ its symmetrization, which defines a cochain $\Psi = C_\delta$. By construction, on vector fields $\xi_i$, we get

$$\psi(\xi_1, \ldots, \xi_n) = C_\delta(\xi_1, \ldots, \xi_n) = \frac{1}{n!} \sum_{\sigma \in S_n} \varepsilon(\sigma) \partial_{i_1} \xi_{\sigma(1)} \partial_{i_2} \xi_{\sigma(2)} \cdots \partial_{i_n} \xi_{\sigma(n)}$$

Thus

$$C_{\delta \delta}(\xi_0, \ldots, \xi_n) = \partial C_\delta(\xi_0, \ldots, \xi_n) = \partial \Psi(\xi_0, \ldots, \xi_n) = d\theta(\xi_0, \ldots, \xi_n) = 0.$$

We now restrict ourselves to the space of linear polyvector fields. This is a subalgebra of $T_{\text{poly}}^d$ equipped with the Schouten bracket; thus we can restrict our coboundary operator to cochains defined on this subalgebra. We get a new operator $\partial_{\text{lin}}$. Our previous computation tells us that the graphs happening in $\partial \delta$ are of the following forms:

For linear polyvector fields, only the first case appears. Then $B_{\partial_{\text{lin}}(\delta)}(\alpha_0, \ldots, \alpha_n)$ vanishes if one of the $\alpha_j$ is not a vector field. And

$$B_{\partial_{\text{lin}}(\delta)}(\xi_0, \ldots, \xi_n) = C_{\delta \delta}(\xi_0, \ldots, \xi_n) = 0.$$

Since the mapping $\gamma \mapsto B_\gamma$ is one-to-one, $\partial_{\text{lin}} \delta = 0$.

Now, suppose $\delta$ is a coboundary $d = \partial_{\text{lin}} \beta$. Then $\beta$ has $n - 1$ vertices and $n - 1$ edges. At each vertex there ends exactly one edge. If there is a vertex $p$ from which no edge emanates, denote by $\vec{p}p$ the edge ending at $p$. Since the graphs in $\beta$ can be deduced from the graphs $\partial_{\text{lin}} \beta$ only by proper reduction, there is no reduction at the vertex $p$, and in $\partial_{\text{lin}} \beta$ there remains a unique edge $\vec{p}p$. But there is no such graph in $\delta$, so we can eliminate in $\beta$ all the graphs with a vertex without emanating edges (we consider only “nonhanded” graphs). Now from each vertex of a graph in $\beta$, there is exactly one edge starting. As previously, the restriction of
\[ \partial \beta \text{ to the vector fields coincides with } \partial_{\text{lin}} \beta, \text{ and} \]
\[ dC_\beta(\xi_0, \ldots, \xi_n) = \partial C_\beta(\xi_0, \ldots, \xi_n) = C_{\partial \beta}(\xi_0, \ldots, \xi_n) \]
\[ = C_{\partial_{\text{lin}} \beta}(\xi_0, \ldots, \xi_n) = C_\delta(\xi_0, \ldots, \xi_n) = \delta(\xi_0, \ldots, \xi_n). \]

This is impossible.

Thus any “wheel without an axis” \( \Delta \) having an odd number of vertices gives rise to a canonical true cocycle for \( \partial_{\text{lin}} \).

**Remark.** Suppose we want to build a linear formality \( \mathcal{F} \) from the space of linear polyvector fields to the space of multidifferential operators. As we saw in Section 2, the obstruction to such a construction is a mapping \( \varphi \), of degree 1, with \( n \geq 4 \) arguments. Such a mapping corresponds to purely aerial graphs with \( n \) vertices and \( 2n - 3 \) edges; in the linear case, we should have \( 2n - 3 \leq n \), which is impossible. Every linear formality at order \( n \) can be extended to a linear formality.
