BASE LOCUS OF LINEAR SYSTEMS ON THE BLOWING-UP OF $\mathbb{P}^3$ ALONG AT MOST 8 GENERAL POINTS

CINDY DE VOLDER AND ANTONIO LAFACE
BASE LOCUS OF LINEAR SYSTEMS ON THE BLOWING-UP OF $\mathbb{P}^3$ ALONG AT MOST 8 GENERAL POINTS

CINDY DE VOLDER AND ANTONIO LAFACE

Consider a (nonempty) linear system of surfaces of degree $d$ in $\mathbb{P}^3$ through at most 8 multiple points in general position and let $\mathcal{L}$ denote the corresponding complete linear system on the blowing-up $X$ of $\mathbb{P}^3$ along those general points. Then we determine the base locus of such linear systems $\mathcal{L}$ on $X$.

1. Introduction

We work over an algebraically closed field of characteristic 0.

Let $P_1, \ldots, P_r$ be general points of the $n$-dimensional projective space $\mathbb{P}^n$ and choose some nonnegative integers $m_1, \ldots, m_r$. Consider the linear system $\mathcal{L}'$ of hypersurfaces of degree $d$ in $\mathbb{P}^n$ having multiplicities at least $m_i$ at $P_i$, for all $i = 1, \ldots, r$. Let $X$ denote the blowing-up of $\mathbb{P}^n$ along $P_1, \ldots, P_r$, and let $\mathcal{L}$ denote the complete linear system on $X$ corresponding to $\mathcal{L}'$.

A point $Q \in X$ is called a basepoint of $\mathcal{L}$ if $Q \in D$ for every divisor $D \in \mathcal{L}$. The scheme-theoretical union of all basepoints of $\mathcal{L}$ is called the base locus of $\mathcal{L}$.

In the case $n = 2$ (i.e., if $X$ is a rational surface obtained by blowing-up $\mathbb{P}^2$ along $r$ general points) the dimension, base locus and other properties of linear systems $\mathcal{L}$ has been widely studied; see, for example, [Chauvin and De Volder 2002; Ciliberto and Miranda 1998; 2001; d'Almeida and Hirschowitz 1992; Gimigliano 1989].

In the case $n = 3$, i.e., if $X$ is a rational threefold obtained by blowing-up $\mathbb{P}^3$ along $r$ general points, very little is known.

In this paper, for $n = 3$ and $r \leq 8$, we will completely describe the base locus of $\mathcal{L}$ on $X$.

If $n = 3$ and $r \leq 8$, the dimension of $\mathcal{L}$ can be determined using the results from [De Volder and Laface 2003]. These results as well as the ones stated in [Harbourne 1985] (concerning the dimension and base locus of linear systems on

MSC2000: 14C20.

Keywords: base locus, linear systems, fat points, projective space.

De Volder is a Postdoctoral Fellow of the Fund for Scientific Research, Flanders (F.W.O.-Vlaanderen). Laface acknowledges the support of the MIUR of the Italian Government in the framework of the National Research Project “Geometry in Algebraic Varieties” (Cofin 2002).
rational surfaces with irreducible reduced anticanonical divisor) will play a crucial role in the main proofs of this paper.

In Sections 2 to 5 we state some preliminaries and notation. The main results are formulated in Section 6, and the last three sections contain their proofs.

2. Preliminaries

Let \( P_1, \ldots, P_8 \) be general points on \( \mathbb{P}^3 \), let \( X \) denote the blowing-up of \( \mathbb{P}^3 \) along these 8 points, denote the projection map by \( \pi : X \to \mathbb{P}^3 \) and let \( E_i \) be the exceptional divisor corresponding to \( P_i \).

By \( \mathcal{L}_3(d; m_1, \ldots, m_r) \), with \( r \leq 8 \), we denote the complete linear system on \( X \) corresponding to the invertible sheaf \( \pi^*(\mathcal{O}_{\mathbb{P}^3}(d)) \otimes \mathcal{O}_X(-m_1 E_1 - \cdots - m_r E_r) \); i.e. the complete linear system corresponding to the linear system of hypersurfaces of degree \( d \) with multiplicities at least \( m_i \) at \( P_i \). Similarly, by \( \mathcal{L}_3(d; m_1', \ldots, m_r') \) (with \( r_1 + \cdots + r_8 \leq 8 \)), we denote the complete linear system on \( X \) corresponding to the linear system of hypersurfaces of degree \( d \) with \( r_j \) points of multiplicities at least \( m_j \).

With \( \langle h, e_1, \ldots, e_r \rangle \) we denote a basis of \( \mathbb{A}^2(X) \), where \( h \) is the pullback of a class of a general line in \( \mathbb{P}^3 \) and \( e_i \) is the class of a line on \( E_i \). The notation \( \ell = \ell_3(\delta, \mu_1, \ldots, \mu_r) \) indicates the set of the strict transforms of all curves in \( \mathbb{P}^3 \) of degree \( \delta \) through \( r \) points of multiplicity \( \mu_1, \ldots, \mu_r \) or equivalently all curves in \( |\delta h - \sum_{i=1}^r \mu_i e_i| \) on \( X \).

For \( 1 \leq i < j \leq 8 \), we denote the strict transform of the line through \( P_i \) and \( P_j \) by \( \ell_{i,j} \).

We say a class \( \mathcal{L}_3(d; m_1, \ldots, m_r) \) is in standard form if \( m_1 \geq \cdots \geq m_r \geq 0 \) and \( 2d \geq m_1 + m_2 + m_3 + m_4 \).

**Lemma 2.1** [De Volder and Laface 2003, Proposition 2.2]. A linear system \( \mathcal{L} = \mathcal{L}_3(d; m_1, \ldots, m_r) \) is in standard form if and only if \( \mathcal{L} = \mathcal{F} + \sum_{i=4}^a c_i \mathcal{F}_i \) with \( c_i \in \mathbb{Z}_{\geq 0}, \mathcal{F}_i = \mathcal{L}_3(2; 1^i) \) and \( \mathcal{F} = \mathcal{L}_3(d - 2m_4, m_1 - m_4, m_2 - m_4, m_3 - m_4) \). \( \square \)

For all \( 1 \leq i \leq 8 \), let \( Q_i \) be a general element of \( \mathcal{F}_i (= \mathcal{L}_3(2; 1^i)) \). Then \( Q_i \) is the blowing-up of \( \tilde{Q}_i \), a general quadric hypersurface in \( \mathbb{P}^3 \) through the points \( P_1, \ldots, P_i \), along those \( i \) points. Also \( \text{Pic} \ Q_i = \langle f_1, f_2, e_1, \ldots, e_i \rangle \), with \( f_1 \) and \( f_2 \) the pullbacks of the two rulings on \( \tilde{Q}_i \) and \( e_1, \ldots, e_i \) the exceptional curves. By \( \mathcal{L}_Q(a, b; m_1, \ldots, m_i) \) we denote the complete linear system \( |af_1 + bf_2 - m_1 e_1 - \cdots - m_i e_i| \), and, as before, if some of the multiplicities are the same, we also use the notation \( \mathcal{L}_Q(a, b; m_1', \ldots, m_r') \).

Let \( B_j \) be the blowing-up of \( \mathbb{P}^2 \) along \( j \) general points. Then

\[
\text{Pic} \ B_j = \langle h, e'_1, \ldots, e'_j \rangle,
\]
with \( h \) the pullback of a line and \( e'_j \) the exceptional curves. By \( \mathcal{L}_2(d; m_1, \ldots, m_j) \) we denote the complete linear system \(|dh - m_1e'_1 - \cdots - m_ge'_g|\). And again, as before, if some of the multiplicities are the same, we also use the notation \( \mathcal{L}_2(d; m_1^{n_1}, \ldots, m_n^{n_r}) \).

On \( B_j \), a system \( \mathcal{L}_2(d; m_1, \ldots, m_j) \) is said to be in standard form if \( d \geq m_1 + m_2 + m_3 \) and \( m_1 \geq m_2 \geq \cdots \geq m_j \geq 0 \); and it is called standard if there exists a base \( \langle \tilde{h}, e_1, \ldots, e_j \rangle \) of Pic \( B_j \) such that \( \mathcal{L}_2(d; m_1, \ldots, m_j) = |\tilde{d}h - m_1e_1 - \cdots - m_je_j| \) is in standard form.

As explained in [De Volder and Laface 2003, §6], the blowing-up \( Q_i \) of the quadric along \( i \) general points can also be seen as a blowing-up of the projective plane along \( i + 1 \) general points, and

\[
\mathcal{L}_{Q_i}(a, b; m_1, \ldots, m_i) = \mathcal{L}_2(a + b - m_1; a - m_1, b - m_1, m_2, \ldots, m_i).
\]

In particular the anticanonical class \(-K_{Q_i}\) contains an irreducible reduced divisor which we denote by \( D_{Q_i} \).

### 3. Cubic Cremona transformation

The cubic Cremona transformation on \( \mathbb{P}^3 \), whose associated rational map is given by

\[
\text{Cr : } \mathbb{P}^3 \rightarrow \mathbb{P}^3 \quad (x_0 : x_1 : x_2 : x_3) \mapsto (x_0^{-1} : x_1^{-1} : x_2^{-1} : x_3^{-1}),
\]

induces an action on Pic \( X \) and one on \( \Lambda^2(X) \), as stated in the next two propositions (see [Laface and Ugaglia 2003] for a proof of both results).

**Proposition 3.1.** Let the Cremona transformation (3–1) use the points \( P_1, \ldots, P_4 \). Its induced action on \( \mathcal{L} = \mathcal{L}_3(d, m_1, \ldots, m_r) \) is given by

\[
\text{Cr}(\mathcal{L}) = \mathcal{L}_3(d+k, m_1+k, \ldots, m_r+ k, m_5, \ldots, m_r),
\]

where \( k = 2d - \sum_{i=1}^{4} m_i \). \( \square \)

**Proposition 3.2.** Let the Cremona transformation (3–1) use the points \( P_1, \ldots, P_4 \). Its induced action on \( \ell = \ell_3(\delta, \mu_1, \ldots, \mu_r) \), with \( \ell \) skew to the \( \ell_{i,j} \) for \( 1 \leq i < j \leq 4 \), is given by

\[
\text{Cr}(\ell) = \ell_3(\delta + 2h, \mu_1 + h, \ldots, \mu_4 + h, \mu_5, \ldots, \mu_r),
\]

where \( h = \delta - \sum_{i=1}^{4} \mu_i \). Moreover, under the same assumption, for all \( 1 \leq i < j \leq 4 \), we have that \( \text{Cr}(\ell_{i,j}) = \ell_{u,v} \), with \( \{i, j, u, v\} = \{1, 2, 3, 4\} \). \( \square \)

**Remark 3.3.** It follows immediately from the previous propositions that the Cremona transformation fixes \( \mathcal{F}_i \) (for \( 4 \leq i \leq 8 \)) and \( K_{Q_i} (= \ell_3(4; 1^8)) \), i.e., \( \text{Cr}(\mathcal{F}_i) = \mathcal{F}_i \) and \( \text{Cr}(K_{Q_i}) = K_{Q_i} \). Moreover \( \text{Cr}(\mathcal{L}).K_{Q_i} = \mathcal{L}.K_{Q_i} \).
Remark 3.4. It can be proved (see [Laface and Ugaglia 2003]) that the cubic Cremona transformation on $X$, is obtained by blowing-up the strict transforms of the six edges of the tetrahedron through the four points used by the cubic Cremona transformation, and blowing down along the other rulings of the exceptional quadrics. This implies in particular that the cubic Cremona transformation is not just a base change of $\text{Pic} X$.

Let $Y$ denote the blowing-up of $X$ along the $l_{1,2}, l_{1,3}, l_{1,4}, l_{2,3}, l_{2,4}$ and $l_{3,4}$. Then

$$\text{Pic} Y = \langle H, E_1, \ldots, E_8, E_{1,2}, \ldots, E_{3,4} \rangle$$

where $H$ is the pullback of a plane in $\mathbb{P}^3$, $E_i$ is the pullback of $E_i$ on $X$ (for all $1 \leq i \leq 8$) and $E_{i,j}$ is the exceptional quadric corresponding to $l_{i,j}$ (for all $1 \leq i < j \leq 4$).

On $Y$ the Cremona transformation using the points $P_1, \ldots, P_4$, is then nothing else than a base change for $\text{Pic} Y$. In particular, in [Laface and Ugaglia 2003], it is shown that

\[
\text{Pic} Y = \langle H, E_1, \ldots, E_8, E_{1,2}, \ldots, E_{3,4} \rangle
\]

\[
= \langle H', F_1, \ldots, F_4, E_5, \ldots, E_8, F_{1,2}, \ldots, F_{3,4} \rangle,
\]

with

\[
\begin{align*}
H' &= \text{Cr}(H) = 3H - \sum_{i=1}^{4} 2E_i - \sum_{1 \leq i < j \leq 4} E_{i,j}, \\
F_k &= \text{Cr}(E_k) = H - \sum_{1 \leq j \leq 4} E_j - \sum_{1 \leq j < l \leq 4, j \neq k} E_{i,j}, \\
F_{i,j} &= \text{Cr}(E_{i,j}) = E_{i,j}, \quad \text{with } \{i, j, k, l\} = \{1, 2, 3, 4\}.
\end{align*}
\]

It follows immediately from these formulas that

\[
\left| dH - \sum_{1 \leq i \leq 4} m_i E_i - \sum_{1 \leq i < j \leq 4} m_{i,j} E_{i,j} \right|
= \left| (d+s)H' - \sum_{1 \leq i \leq 4} (m_i + s)F_i - \sum_{1 \leq i < j \leq 4} (d - m_k - m_l + m_{k,l})F_{i,j} \right|
\]

Similarly, for $\mathbb{A}^2(Y)$, we have, by [Laface and Ugaglia 2003],

\[
\mathbb{A}^2(Y) = \langle h, e_1, \ldots, e_8, e_{1,2}, \ldots, e_{3,4} \rangle
\]

\[
= \langle h', f_1, \ldots, f_4, e_5, \ldots, e_8, f_{1,2}, \ldots, f_{3,4} \rangle.
\]
with \( h \) the pullback of a line in \( \mathbb{P}^3 \), \( e_l \) the class of a line in \( E_l \), \( e_{i,j} \) the vertical ruling of \( E_{i,j} \) and

\[
\begin{align*}
\begin{cases}
\quad h' = \text{Cr}(h) = 3h - \sum_{i=1}^{4} e_i, \\
\quad f_k = \text{Cr}(e_k) = 2h - \sum_{1 \leq j \leq 4, \ j \neq k} e_j, \\
\quad f_{i,j} = \text{Cr}(e_{i,j}) = h + e_{k,l} - e_k - e_l, \\
\end{cases}
\end{align*}
\tag{3–8}
\]

Henceforth, we will use sheaf notation (as in \( \pi^*(\mathcal{O}_{\mathbb{P}^3}(d)) \otimes \mathcal{O}_X(-m_1 E_1) \)) as well as linear system notation (as in \( |dH - m_1 E_1| \)) for both purposes. It should be clear from the context which one is intended.

4. \((-1)\)-curves on \( X \)

A curve \( C \in \ell = \ell_3(\delta, \mu_1, \ldots, \mu_4) \) is called a \((-1)\)-curve if \( \ell \) is obtained by applying a finite set of cubic Cremona transformations on the system \( \ell_3(1, 1^2) \).

For all \( a \in \mathbb{Z}_{\geq 0} \) and distinct \( b, c \in \{1, \ldots, 8\} \), set

\[
\delta_{i;b,c} = \begin{cases}
0 & \text{if } i \notin \{b, c\}, \\
1 & \text{if } i \in \{b, c\};
\end{cases}
\]

and

\[
\ell_a^{b,c} = \begin{cases}
\ell_3(2a + 1; \frac{1}{2}a + \delta_{1;b,c}, \frac{1}{2}a + \delta_{2;b,c}, \ldots, \frac{1}{2}a + \delta_{8;b,c}) & \text{if } a \text{ is even}, \\
\ell_3(2a + 1; \frac{1}{2}(a + 1) - \delta_{1;b,c}, \frac{1}{2}(a + 1) - \delta_{2;b,c}, \ldots, \frac{1}{2}(a + 1) - \delta_{8;b,c}) & \text{if } a \text{ is odd}.
\end{cases}
\]

**Lemma 4.1.** A curve \( C \in \ell \) on \( X \) is a \((-1)\)-curve if and only if there exists \( a \in \mathbb{Z}_{\geq 0} \) and \( b, c \in \{1, \ldots, 8\} \), \( b \neq c \), such that \( \ell = \ell_a^{b,c} \).

**Proof.** First of all, note that \( \ell_{i,j} = \ell_0^{i,j} \). So all \( \ell_0^{i,j} \) are classes of \((-1)\)-curves. To simplify notation, we now assume that \( i = 1 \) and \( j = 2 \), and by \( B \) we denote the set of the four indices of the points used for the transformation \((3–1)\). To determine \( \text{Cr}(\ell_{1,2}) \) we distinguish three cases:

(a) \( P_1 \) and \( P_2 \in B \). Without loss of generality we may assume that the transformation \((3–1)\) uses the points \( P_1, \ldots, P_4 \), i.e. that \( B = \{1, 2, 3, 4\} \). So, by Proposition 3.2 we obtain that \( \text{Cr}(\ell_{1,2}) = \ell_{3,4} \), i.e. \( \text{Cr}(\ell_{1,2}^{0,1,2}) = \ell_{0}^{3,4} \).

(b) \( P_2 \in B \) and \( P_1 \notin B \). Then we may assume that \( B = \{2, 3, 4, 5\} \). So, by Proposition 3.2 we obtain that \( \text{Cr}(\ell_{1,2}) = \ell_{1,2} \), i.e. \( \text{Cr}(\ell_{1,2}^{0,1,2}) = \ell_{0}^{1,2} \).
(c) $P_1$ nor $P_2$ is used for the transformation $(3\!-\!1)$. Then we may assume that $B = \{3, 4, 5, 6\}$. So, by Proposition 3.2 we obtain that $\text{Cr}(\ell_{1,2}) = \ell_3(3; 1^6)$, i.e. $\text{Cr}(\ell_{1,2}^1) = \ell_1^{7,8}$.

Since we can do this for any $i, j$, we conclude that all $\ell_{i,j}^1$ are classes of $(-1)$-curves. Similarly, one can see that, for $a$ odd,

$$ \text{Cr}(\ell_{i,j}^1) = \begin{cases} 
\ell_{3,4}^1 & \text{if } B = \{1, 2, 3, 4\}, \\
\ell_{1,2}^1 & \text{if } B = \{2, 3, 4, 5\}, \\
\ell_{7,8} & \text{if } B = \{3, 4, 5, 6\}; 
\end{cases} $$

and, for $a$ even (and $a > 0$),

$$ \text{Cr}(\ell_{i,j}^1) = \begin{cases} 
\ell_{3,4}^1 & \text{if } B = \{1, 2, 3, 4\}, \\
\ell_{1,2}^1 & \text{if } B = \{2, 3, 4, 5\}, \\
\ell_{7,8} & \text{if } B = \{3, 4, 5, 6\}; 
\end{cases} $$

So, we can obtain all classes of type $\ell_{i,j}^1$, and no others. \hfill \Box

**Remark 4.2.** Lemma 4.1 implies that $\ell_{i,j}^{b,c}$ contains precisely one (irreducible) curve, which we denote by $C_{a}^{b,c}$. If $a$ is even, $C_{a}^{b,c}$ is the strict transform of a curve of degree $2a + 1$ with multiplicity $\frac{1}{2}a$ at $P_i$ for $i \not\in \{b, c\}$ and multiplicity $\frac{1}{2}a + 1$ at $P_b$ and $P_c$. If $a$ is odd, $C_{a}^{b,c}$ is the strict transform of a curve of degree $2a + 1$ with multiplicity $\frac{1}{2}(a + 1)$ at $P_i$ for $i \not\in \{b, c\}$ and multiplicity $\frac{1}{2}(a - 1)$ at $P_b$ and $P_c$.

5. Blowings-up of Hirzebruch surfaces along general points

Let $\mathbb{F}_n$ be a Hirzebruch surface with $n > 0$, i.e. $\mathbb{F}_n$ is the geometrically ruled surface over $\mathbb{P}^1$ determined by the vector bundle $\mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(n)$. Then $\text{Pic} \mathbb{F}_n = \langle f, h_n \rangle = \langle f, c_n \rangle$ with $f^2 = 0, h_0, f = 1, h_n^2 = n, c_n = h_n - nf$ and $c_n^2 = -n$; see, for example, [Beauville 1996, Proposition IV.1].

Now let $\mathbb{F}_n^j$ be the blowing-up of $\mathbb{F}_n$ along $j$ general points. By abuse of notation, let $f, h_n$ and $c_n$ also denote the pullbacks of these curves on $\mathbb{F}_n^j$, then $\text{Pic} \mathbb{F}_n^j = \langle f, c_n, e_1, \ldots, e_j \rangle$, where $e_1, \ldots, e_j$ are the exceptional divisors.

**Lemma 5.1.** The surface $\mathbb{F}_n^1$, with $n > 1$, can also be seen as the blowing-up of an $\mathbb{F}_{n-1}$ along a general point of $c_{n-1}$. In particular $\text{Pic} \mathbb{F}_n^1 = \langle f, h_{n-1}, e'_1 \rangle$ with $h_{n-1} = h_n - e_1$ and $e'_1 = f - e_1$ the exceptional divisor corresponding to the blown-up point on $c_{n-1}$. Moreover $af + \beta h_{n-1} - me_1 = (\alpha + \beta - m)f + \beta h_{n-1} - (\beta - m)e'_1$.

**Proof.** The last equality follows immediately, using $h_{n-1} = h_n - e_1$ and $e'_1 = f - e_1$, so $\text{Pic} \mathbb{F}_n^1 = \langle f, h_{n-1}, e'_1 \rangle$ is true. Note that $e'_1^2 = -1$ and $h_{n-1}^2 = n - 1$. Consider $c_{n-1} = h_{n-1} - (n - 1)f = c_n + e'_1$, then $c_{n-1}^2 = -(n - 1)$.
Now, let $b: \mathbb{F}_n^1 \to V$ denote the map obtained by blowing down $e_i'$, then $\text{Pic}(V) = \langle f, h_n \rangle = \langle f, c_{n-1} \rangle$, and $b(e_i') = Q_1$ is a (general) point on $c_{n-1}$ which is an irreducible curve on $V$ of negative self-intersection. So $V = \mathbb{F}_{n-1}$ and $\mathbb{F}_n^1$ is the blowing-up of $\mathbb{F}_{n-1}$ along the point $Q_1 \in c_{n-1}$. □

**Corollary 5.2.** The surface $\mathbb{F}_{n-1}$ can also be seen as the blowing-up of an $\mathbb{F}_1$ along $n - 1$ general points of $c_1$. In particular $\text{Pic}\mathbb{F}_{n-1} = \langle f, h_1, e_1', \ldots, e_{n-1}' \rangle$ with $h_1 = h_n - e_1 - \cdots - e_{n-1}$ and $e_i' = f - e_i$ for all $i = 1, \ldots, n - 1$. Moreover $\alpha f + \beta h_n - m_1 e_1 - \cdots - m_{n-1} e_{n-1} = (\alpha + (n-1) \beta - m_1 - \cdots - m_{n-1}) f + \beta h_n - (\beta - m_1) e_1' - \cdots - (\beta - m_{n-1}) e_{n-1}'$.

**Proof.** This follows immediately by applying Lemma 5.1 $n - 1$ times. □

6. Base locus of linear systems on $X$

A point $P$ of $X$ is called a basepoint of a linear system $\mathcal{L} = L_3(d; m_1, \ldots, m_r)$ if $P \in D$ for all $D \in \mathcal{L}$.

A divisor $F$ on $X$ is called a fixed component of $\mathcal{L}$ if $F \subset D$ for all $D \in \mathcal{L}$.

The base locus of $\mathcal{L}$, which we denote by $\text{Bs}(\mathcal{L})$, is defined as the scheme-theoretical union of all basepoints.

**Example 6.1.** $\text{Bs}(L_3(2; 2^3)) = 2H$, with $H$ the unique element of $L_3(1; 1^3)$.

Since an empty system obviously has no base locus, we only consider nonempty linear systems on $X$ (the results from [De Volder and Laface 2003] can be used to determine whether or not a system is empty).

The main results of this paper are the following:

**Theorem 6.2.** Let $\mathcal{L} = L_3(d; m_1, \ldots, m_r) = \mathcal{L} + \sum_{i=4}^r c_i \mathcal{L}_i$, $r \leq 8$, be (nonempty and) in standard form on $X$.

(1) if $d \geq m_1 + m_2$ and $\mathcal{L} \notin \{L_3(2m; m^8), L_3(2m; m^7, m-1)\}$ then $\mathcal{L}$ is basepoint-free;

(2) if $\mathcal{L} = L_3(2m; m^8)$ ($m \geq 1$) then $\text{Bs}(\mathcal{L}) = mD_{Q_8}$;

(3) if $\mathcal{L} = L_3(2m; m^7, m-1)$ ($m \geq 1$) then $\text{Bs}(\mathcal{L}) = mP$ where $P$ is the unique basepoint of $\mathcal{L}|_{Q_8}$ (which is a point on $D_{Q_8}$);

(4) if $d < m_1 + m_2$, then $\text{Bs}(\mathcal{L}) = \sum_{n,j > 0} t_{i,j} \ell_{i,j}$, with $t_{i,j} = m_i + m_j - d$ ($i \neq j$) and $\ell_{i,j}$ the strict transform of the line through $P_i$ and $P_j$.

**Remark 6.3.** Theorem 6.2 implies in particular that a class in standard form does not have fixed components.

**Theorem 6.4.** Consider the (nonempty) linear system $\mathcal{L} = L_3(d; m_1, \ldots, m_r)$, $r \leq 8$, on $X$, then one can obtain the fixed components of $\mathcal{L}$ as follows:

(1) Renumber the multiplicities such that $m_1 \geq m_2 \geq \cdots \geq m_r$. 
(2) If $2d < m_1 + m_2 + m_3 + m_4$ then apply the cubic Cremona transformation to these 4 multiplicities and goto (1); otherwise goto (3).

(3) If $m_i < 0$ then $-m_i E'_i$ is a fixed component, and you can apply the cubic Cremona transforms in the opposite direction to obtain the class $F_i$ that corresponds to $E'_i$ in the original situation; $-m_i F_i$ then belongs to the fixed components of $\mathcal{L}$. Moreover, in this way you obtain all fixed components of $\mathcal{L}$.

**Theorem 6.5.** Let $\mathcal{L} = \mathcal{L}_3(d; m_1, \ldots, m_r)$ be a (nonempty) linear system on $X$ with $m_1 \geq \cdots \geq m_r$. Assume that $\mathcal{L}$ has no fixed components and that $\mathcal{L}$ is not in standard form. Define $t^{b,c}_a := -\mathcal{L} \cdot \mathcal{L}'_{a}^{b,c}$.

(1) If $4d - \sum_{i=1}^{r} m_i \neq 1$ then

$$\text{Bs}(\mathcal{L}) = \sum_{t^{b,c}_a > 0} t^{b,c}_a C^{b,c}_a.$$ 

(2) If $4d - \sum_{i=1}^{r} m_i (= \mathcal{L} \cdot D_{Q8}) = 1$ then $\mathcal{L}$ can be transformed, by a finite number of Cremona transformations, into $\mathcal{L}_3(2m; m^7, m - 1)$ for some $m > 0$, and

$$\text{Bs}(\mathcal{L}) = \sum_{t^{b,c}_a > 0} t^{b,c}_a C^{b,c}_a + m P,$$

with $P$ the unique basepoint of $\mathcal{L}$ on $D_{Q8}$.

**Remark 6.6.** Using Theorems 6.2, 6.4 and 6.5, we can completely determine the base locus of any linear system $\mathcal{L}$ on $X$. Indeed, using Theorem 6.4, you can write $\mathcal{L}$ as $F + \mathcal{L}'$, with $F$ the fixed components of $\mathcal{L}$ and $\mathcal{L}'$ without fixed components. Then, using either Theorem 6.2 or 6.5, depending on whether or not $\mathcal{L}'$ is in standard form, you can obtain $\text{Bs}(\mathcal{L}')$. But since $\text{Bs}(\mathcal{L}) = F + \text{Bs}(\mathcal{L}')$, you then also know the base locus of $\mathcal{L}$.

**Example 6.7.** Consider the linear system $\mathcal{L} = \mathcal{L}_3(15; 13, 10, 9, 7, 6, 3^2, 2)$ on $X$.

First, we apply the algorithm of Theorem 6.4 to determine the fixed components of $\mathcal{L}$. We use the following diagram (where Step 1 consists of marking the four biggest multiplicities):

<table>
<thead>
<tr>
<th></th>
<th>15</th>
<th>13</th>
<th>10</th>
<th>9</th>
<th>7</th>
<th>6</th>
<th>3</th>
<th>3</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>4</td>
<td>1</td>
<td>0</td>
<td>-2</td>
<td>6</td>
<td>3</td>
<td>3</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>-2</td>
<td>2</td>
<td>-1</td>
<td>-1</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>-1</td>
<td>0</td>
<td>0</td>
<td>-2</td>
<td>1</td>
<td>-1</td>
<td>-1</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

So, after applying the cubic Cremona transform 3 times, we obtain that $E'_1 + 2E'_4 + E'_6 + E'_7$ is the fixed part. In order to go back to the original situation, we now
apply the three cubic Cremona transforms in opposite order. For instance, for $E'_1$ we obtain

$$
\begin{bmatrix}
0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\
2 & 1 & 1 & 0 & 0 & 2 & 1 & 1 \\
4 & 3 & 3 & 2 & 2 & 2 & 1 & 1 & 1
\end{bmatrix}
$$

Proceeding in the same way for the other $E'_i$, we deduce that the fixed components of $\mathcal{L}$ are $F = F_1 + 2F_2 + F_3 + F_4$, with $F_1 \in \mathcal{L}_3(4; 3^2, 2^3, 1^3)$, $F_2 \in \mathcal{L}_3(1; 1^3)$, $F_3 \in \mathcal{L}_3(2; 2, 1^4, 0, 1, 0)$ and $F_4 \in \mathcal{L}_3(2; 1, 1^5)$.

Now consider $\mathcal{L}' := \mathcal{L} - F$. Then $\mathcal{L}' = \mathcal{L}_3(5; 4, 3^3, 2, 1^3)$ is a system without fixed components and not in standard form, so we can apply Theorem 6.5 to obtain

$$
\text{Bs}(\mathcal{L}') = \sum_{2 \leq i \leq 4} 2 C^{1,i}_0 + C^{1,5}_0 + \sum_{2 \leq i < j \leq 4} C^{i,j}_0 + \sum_{6 \leq i < j \leq 8} C^{i,j}_1
$$

and

$$
\text{Bs}(\mathcal{L}) = F_1 + 2F_2 + F_3 + F_4 + \text{Bs}(\mathcal{L}')
$$

7. Proof of Theorem 6.2

Without loss of generality, we may assume that $m_r > 0$.

(1) In case $r > 4$, we consider the exact sequence

$$
0 \rightarrow \mathcal{L} - \mathcal{L}_r \rightarrow \mathcal{L} \rightarrow \mathcal{L} \otimes \mathcal{O}_{Q_r} \rightarrow 0.
$$

We then have

$$
\mathcal{L} \otimes \mathcal{O}_{Q_r} = \mathcal{L}_{Q_r}(d, d; m_1, \ldots, m_r) = \mathcal{L}_2(2d - m_1; (d - m_1)^2, m_2, \ldots, m_r).
$$

Also, using [De Volder and Laface 2003, Theorem 5.3], we know that $h^1(\mathcal{L} - \mathcal{L}_r) = h^1(\mathcal{L}) = 0$, so $\mathcal{L}|_{Q_r} = \mathcal{L} \otimes \mathcal{O}_{Q_r}$; that is,

$$
\mathcal{L}|_{Q_r} = \mathcal{L}_2(2d - m_1; (d - m_1)^2, m_2, \ldots, m_r).
$$

Since $d \geq m_1 + m_2$, we see that $d - m_1 \geq m_2(\geq m_3 \geq \cdots \geq m_r)$. On the other hand $2d - m_1 \geq 2(d - m_1) + m_2$ and $\mathcal{L}|_{Q_r}.K_{Q_r} = -4d + m_1 + \cdots + m_r < -1$ (the inequality is true because $\mathcal{L} \notin \mathcal{L}_3(2m; m^8)$, $\mathcal{L}_3(2m; m^7, m - 1)$). This means that we can apply [Harbourne 1985, Theorem 3.1 and Corollary 3.4] to conclude that $\mathcal{L}|_{Q_r}$ is basepoint-free or thus that $\mathcal{L}$ has no basepoints on $Q_r$.

Proceed using the exact sequence (7–1), replacing $\mathcal{L}$ by $\mathcal{L} - \mathcal{L}_r$, then by $\mathcal{L} - 2\mathcal{L}_r$ and so on, until the residue class becomes $\mathcal{L} - c_r\mathcal{L}_r$.

Now, let $b$ be $\max\{i < r : c_i > 0\}$, and, if $b \geq 4$, again use the same arguments, now using $Q_b$ in stead of $Q_r$. 
Continuing in this way, we reduce the proof of the basepoint-freeness of $\mathcal{L}$ to proving it for the case $r \leq 3$; that is, to proving the basepoint-freeness of $\mathcal{F}$.

In order to see that $\mathcal{F}$ is basepoint-free, let $H$ be the unique element of $\mathcal{L}^*(1; 1^3)$ and consider the exact sequence

$$(7-2) \quad 0 \longrightarrow \mathcal{F} - \mathcal{L}^*(1; 1^3) \longrightarrow \mathcal{F} \longrightarrow \mathcal{F} \otimes \mathcal{O}_H \longrightarrow 0.$$  

Using [De Volder and Laface 2003, Theorem 5.3], we know that

$$h^1(\mathcal{F} - \mathcal{L}^*(1; 1^3)) = h^1(\mathcal{F}) = 0,$$

so $\mathcal{F}|_H = \mathcal{F} \otimes \mathcal{O}_H$. But $\mathcal{F} \otimes \mathcal{O}_H = \mathcal{L}(d - 2m_4; m_1 - m_4, m_2 - m_4, m_3 - m_4)$, which is basepoint-free (since $d \geq m_1 + m_2$).

We can use this procedure to see that if $\mathcal{L}(d - m_3 - m_4; m_1 - m_3, m_2 - m_3)$, is basepoint-free then $\mathcal{F}$ is basepoint-free.

Then proceed in the same way, but use a general $H' \in \mathcal{L}^*(1; 1^2)$ until the residue class is $\mathcal{L}(d - m_2 - m_4; m_1 - m_2)$; and after this, use a general $H'' \in \mathcal{L}^*(1; 1)$ until the residue class is $\mathcal{L}(d - m_1 - m_4)$.

So we actually only need to prove that $\mathcal{L}(d - m_1 - m_4)$ is basepoint-free, but this is obviously true since $d - m_1 - m_4 \geq 0$.

(2) We use induction on $m$ to prove that $\text{Bs}(\mathcal{L}) = mD_{Q_8}$.

In case $m = 1$, $Q_8 \in \mathcal{L} = \mathcal{F}_8$ and we can consider the exact sequence

$$0 \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{F}_8 \longrightarrow \mathcal{F}_8 \otimes \mathcal{O}_{Q_8} \longrightarrow 0.$$  

Since $h^1(\mathcal{F}_8) = h^1(\mathcal{O}_X) = 0$, we have $\mathcal{F}_8|_{Q_8} = \mathcal{F}_8 \otimes \mathcal{O}_{Q_8}$. So $\mathcal{F}_8|_{Q_8} = \mathcal{L}_2(3; 1^3) = -K_{Q_8}$, and $D_8$, the unique element of $-K_{Q_8}$, is the fixed locus of $\mathcal{F}_8|_{Q_8}$ and thus also of $\mathcal{L}$.

Now assume that $m > 1$ and that the statement is true for all $m' \leq m - 1$. Consider the exact sequence

$$0 \longrightarrow \mathcal{L} - \mathcal{F}_8 \longrightarrow \mathcal{L} \longrightarrow \mathcal{L} \otimes \mathcal{O}_{Q_8} \longrightarrow 0.$$  

Since $\mathcal{L} = \mathcal{L}_3(2m; m^8)$ and $\mathcal{L} - \mathcal{F}_8 = \mathcal{L}_3(2(m - 1); (m - 1)^8)$, we see that $d \geq m_1 + m_2$ for $\mathcal{L}$ and $\mathcal{L} - \mathcal{F}_8$. So, because of [De Volder and Laface 2003, Theorem 5.3], we know that $h^1(\mathcal{L} - \mathcal{F}_8) = h^1(\mathcal{L}) = 0$. Thus we obtain $\mathcal{L}|_{Q_8} = \mathcal{L} \otimes \mathcal{O}_{Q_8} = -mK_{Q_8}$.

The only element of $-mK_{Q_8}$ is $mD_{Q_8}$; thus $\text{Bs}(\mathcal{L}) = D_{Q_8} = \text{Bs}(\mathcal{L} - \mathcal{F}_8)$ and $\mathcal{L} - \mathcal{F}_8 = \mathcal{L}_3(2(m - 1); (m - 1)^8)$. By induction we obtain $\text{Bs}(\mathcal{L}) = mD_{Q_8}$.

(3) The same procedure as in (2) can be used. The only difference being that $\mathcal{L}|_{Q_8} = \mathcal{L}_2(3m; m^8, m - 1)$, which has exactly one basepoint $P$ on $D_{Q_8}$; see [Harbourne 1985, Corollary 3.4].
(4) Since obviously \( \sum_{i,j > 0} t_{i,j} \ell_{i,j} \subset \text{Bs}(\mathcal{L}) \), it is sufficient to show that \( \text{Bs}(\mathcal{L}) \subset \sum_{i,j > 0} t_{i,j} \ell_{i,j} \). To do this, we have to distinguish between \( \mathcal{I} \neq \emptyset \) and \( \mathcal{I} = \emptyset \).

- In the case \( \mathcal{I} \neq \emptyset \), \( d \geq m_1 + m_4 \), and thus also \( t_{i,j} \leq 0 \) for all \( i \geq 1 \) and \( j \geq 4 \). Now consider the exact sequence \((7-1)\). Using [De Volder and Laface 2003, Theorem 5.3], we see that \( h^1(\mathcal{L} - \mathcal{I}_r) = h^1(\mathcal{I})(\neq 0) \), and, because of Lemma 5.2 of the same reference, \( h^1(\mathcal{L} \otimes \mathcal{O}_{Q_r}) = 0 \), so

\[
\mathcal{L}|_{Q_r} = \mathcal{L} \otimes \mathcal{O}_{Q_r} = \mathcal{L}_2(2d - m_1; (d - m_1)^2, m_2, \ldots, m_r).
\]

On the other hand, \( \mathcal{L}|_{Q_r}.K_{Q_r} = -4d + m_1 + \cdots + m_r < -1 \) (the inequality is true because \( \mathcal{L} \notin \{\mathcal{L}_3(2m; m^2), \mathcal{L}_3(2m; m^2, m - 1)\} \) and \( \mathcal{L}|_{Q_r} \) is standard (see the proof of [De Volder and Laface 2003, Lemma 5.2]). This means that we can apply [Harbourne 1985, Theorem 3.1 and Corollary 3.4] to conclude that \( \mathcal{L}|_{Q_r} \) is basepoint-free or thus that \( \mathcal{L} \) has no basepoints on \( Q_r \).

Continuing this procedure as in (1), we see that \( \text{Bs}(\mathcal{L}) \subset \text{Bs}(\mathcal{I}) \).

Now consider the exact sequence \((7-2)\). Using [De Volder and Laface 2003, Theorem 5.3], we obtain

\[
h^1(\mathcal{I}) = \sum_{t_{i,j} \geq 2} \left( \frac{t_{i,j} + 1}{3} \right) \quad \text{and} \quad h^1(\mathcal{I} - \mathcal{L}_3(1; 1^3)) = \sum_{t_{i,j} \geq 2} \left( \frac{t_{i,j}}{3} \right).
\]

So \( h^1(\mathcal{I}) - h^1(\mathcal{I} - \mathcal{L}_3(1; 1^3)) = h^1(\mathcal{I} \otimes \mathcal{O}_H) \), which implies that \( \mathcal{I}|_H = \mathcal{I} \otimes \mathcal{O}_H \).

Since \( \text{Bs}(\mathcal{I} \otimes \mathcal{O}_H) = \sum_{t_{i,j} \geq 1} t_{i,j} \ell_{i,j} \), we see that

\[
\text{Bs}(\mathcal{I}) = \sum_{t_{i,j} \geq 1} t_{i,j} \ell_{i,j} + \text{Bs}(\mathcal{I} - \mathcal{L}_3(1; 1^3)).
\]

Again continuing as in (1), we finally get \( \text{Bs}(\mathcal{L}) = \text{Bs}(\mathcal{I}) = \sum_{t_{i,j} \geq 1} t_{i,j} \ell_{i,j} \).

- In the case \( \mathcal{I} = \emptyset \), \( d < m_1 + m_4 \), i.e. \( t_{1,2} \geq t_{1,3} \geq t_{1,4} > 0 \) (and thus also \( r \geq 4 \)). Moreover \( 2d \geq m_1 + m_2 + m_3 + m_4 \), so \( d > m_2 + m_3 \), and thus \( t_{i,j} \leq 0 \) for all \( 2 \leq i < j \).

Let \( W_r \) be a general element of \( \mathcal{L}_3(2; 2, 1^5) \) with \( x = \min\{r - 1, 5\} \), i.e. \( W_r \) corresponds in \( \mathbb{P}^3 \) with an irreducible cone with vertex \( P_1 \) and through the points \( P_2, \ldots, P_{x+1} \). Then (in \( X) \) \( W_r \) is the blowing-up of a Hirzebruch surface \( \mathbb{F}_2 \) along \( x \) general points, and \( \text{Pic}(W_r) = \langle f, h_2, e_2, \ldots, e_{x+1} \rangle = \langle f, c_2, e_2, \ldots, e_{x+1} \rangle \), with \( c_2 = h_2 - 2f, \mathcal{L}_3(1)|_{W_r} = h_2, E_1|_{W_r} = c_2 \) and \( E_i|_{W_r} = e_1 \) for all \( i = 2, \ldots, x + 1 \).

Now consider the exact sequence

\[
0 \longrightarrow \mathcal{L} - \mathcal{L}_3(2; 2, 1^5) \longrightarrow \mathcal{L} \longrightarrow \mathcal{L} \otimes \mathcal{O}_{W_r} \longrightarrow 0.
\]

Because of [De Volder and Laface 2003, Theorem 5.3], we know that \( h^1(\mathcal{L}) = \sum_{t_{i,j} > 0} \binom{t_{i,j} + 1}{3} \).
Claim 7.1. \( h^1(\mathcal{L} \otimes \mathcal{O}_{W_r}) = \sum_{t_{i,j}>0, j \leq x+1} \binom{t_{i,j}}{2} \) and \( \text{Bs}(\mathcal{L} \otimes \mathcal{O}_{W_r}) = \sum_{t_{i,j}>0, j \leq x+1} t_{i,j} \ell_{1,j} \).

Claim 7.2. The linear system \( \mathcal{L} - \mathcal{L}_3(2; 2, 1^x) \) is in standard form unless \( \mathcal{L} = \mathcal{L}_3(m + m' + t; m' + 2t, m', m^6) \) for some \( m' \geq m \geq t > 0 \). Moreover

\[
h^1(\mathcal{L} - \mathcal{L}_3(2; 2, 1^x)) = \sum_{t_{i,j}>0, j \leq x+1} \binom{t_{i,j}}{3} + \sum_{x+1 < j \leq r} \binom{t_{i,j}+1}{3}.
\]

Using these two claims, we obtain

\[
\mathcal{L}|_{W_r} = \mathcal{L} \otimes \mathcal{O}_{W_r} \quad \text{and} \quad \text{Bs}(\mathcal{L}|_{W_r}) = \sum_{t_{i,j}>0, j \leq x} t_{i,j} \ell_{1,j}.
\]

Thus

\[
\text{Bs}(\mathcal{L}) \subseteq \text{Bs}(\mathcal{L} - \mathcal{L}_3(2; 2, 1^x)) + \sum_{t_{i,j}>0, j \leq x+1} \ell_{1,j}.
\]

If \( r > 6 \), let \( H \) be a general element of \( \mathcal{L}_3(1; 1, 0^5, 1^{r-6}) \), denote \( \mathcal{L} - \mathcal{L}_3(2; 2, 1^5) \) by \( \tilde{\mathcal{L}} \) and consider the exact sequence

\[
0 \longrightarrow \mathcal{L} - \mathcal{L}_3(3; 3, 1^{r-1}) \longrightarrow \tilde{\mathcal{L}} \longrightarrow \tilde{\mathcal{L}} \otimes \mathcal{O}_H \longrightarrow 0.
\]

Claim 7.3. \( h^1(\tilde{\mathcal{L}} \otimes \mathcal{O}_H) = \sum_{t_{i,j}>0, 6 < j \leq r} \binom{t_{i,j}}{2} \) and \( \text{Bs}(\tilde{\mathcal{L}} \otimes \mathcal{O}_H) = \sum_{t_{i,j}>0, 6 < j \leq r} t_{i,j} \ell_{1,j} \).

Claim 7.4. The linear system \( \mathcal{L} - \mathcal{L}_3(3; 3, 1^{r-1}) \) is in standard form and

\[
h^1(\mathcal{L} - \mathcal{L}_3(3; 3, 1^{r-1})) = \sum_{t_{i,j}>0} \binom{t_{i,j}}{3}.
\]

Using Claims 7.2 and 7.4, we obtain \( \tilde{\mathcal{L}}|_H = \tilde{\mathcal{L}} \otimes \mathcal{O}_H \) and

\[
\text{Bs}(\tilde{\mathcal{L}}|_H) = \sum_{t_{i,j}>0, 6 < j \leq r} t_{i,j} \ell_{1,j}.
\]

Now define

\[
\mathcal{L}' = \mathcal{L}_3(d'; m_1', \ldots, m_r') := \begin{cases} \mathcal{L} - \mathcal{L}_3(2; 2, 1^x) & \text{if } r \leq 6, \\ \mathcal{L} - \mathcal{L}_3(3; 3, 1^{r-1}) & \text{if } r > 6. \end{cases}
\]

and \( t'_{i,j} := m'_i + m'_j - d' \). Then \( d' = d - 3, m'_1 = m_1 - 3, m'_i = m_i - 1 \) for \( 2 \leq i \leq r \); \( t'_{1,j} = t_{1,j} - 1 \) for \( 2 \leq j \leq r \); and \( t'_{i,j} = t_{i,j} + 1 \) for \( 2 \leq i < j \leq r \). In particular, \( t'_{i,j} \leq t'_{2,3} = t_{2,3} + 1 \leq -t_{1,4} + 1 \leq 0 \) for \( 2 \leq i < j \leq r \).
If \( t_{1,4} > 0 \) (so \( t_{1,4} \geq 2 \)), then, since \( \mathcal{L}' \) is in standard form (by Claims 7.2 and 7.4), we can start our procedure again, and we can do this until \( t_{1,4}' = 0 \) for some \( \mathcal{L}' \). Thus we obtain
\[
\text{Bs}(\mathcal{L}) \subset \text{Bs}(\mathcal{L}') + \sum_{t_{1,j} > 0} \alpha_j \ell_{1,j}
\]
in any case, with
\[
\alpha_j = \begin{cases} 
t_{1,j} & \text{if } m_j' = 0, \\
\min\{m_j - m_j', t_{1,j}\} & \text{if } m_j' > 0.
\end{cases}
\]

Because of Claims 7.2 and 7.4, we also know that \( \mathcal{L}' \) is in standard form, which means that we are in one of the previously treated cases of our theorem (since \( t_{1,4} = 0 \)).

If we are in case (1) or in case (4) with \( \mathcal{L} \neq \emptyset \), then we immediately obtain
\[
\text{Bs}(\mathcal{L}) \subset \sum_{t_{1,j} > 0} t_{1,j} \ell_{1,j}.
\]

In case (2), we obtain \( \mathcal{L}' = \mathcal{L}_3(2m; m^8) \), for some \( m \geq 1 \), \( \text{Bs}(\mathcal{L}') = mD_{Q_8} \), and \( \mathcal{L} = \mathcal{L}_3(2m; m^8) + y\mathcal{L}_3(3; 3, 1^7) \) (\( y > 0 \)). So \( t_{1,i} = y \) for all \( 2 \leq i \leq 8 \) and \( \text{Bs}(\mathcal{L}) \subset mD_{Q_8} + \sum_{j=1}^{8} y\ell_{1,j} \) and, as \( D_{Q_8} \subset Q_8 \), it is sufficient to prove that \( \mathcal{L} \) is basepoint-free on \( Q_8 \).

Consider the exact sequence (7–1). Then, because of [De Volder and Laface 2003, Theorem 5.3] we know that \( h^1(\mathcal{L} - Q_{O}) = h^1(\mathcal{L}) = 8(1^+1) \). On the other hand, \( h^1(\mathcal{L} \otimes Q_8) = 0 \) by [De Volder and Laface 2003, Lemma 5.2], so \( \mathcal{L}|Q_8 = \mathcal{L} \otimes Q_8 = \mathcal{L}_2(3m + 3y; m^2, (m + y)^7) \), which is basepoint-free, since it is in standard form and \( \mathcal{L}|Q_8.K_{Q_8} = -2y \leq -2 \) (see [Harbourne 1985, Corollary 3.4]).

In case (3), we obtain \( \mathcal{L}' = \mathcal{L}_3(2m; m^7, m - 1) \), for some \( m \geq 1 \), \( \text{Bs}(\mathcal{L}') = mP \) and \( \mathcal{L} = \mathcal{L}_3(2m; m^7, m - 1) + y\mathcal{L}_3(3; 3, 1^7) \) (\( y > 0 \)) or
\[
\mathcal{L} = \mathcal{L}_3(2; 1^7) + y'\mathcal{L}_3(3; 3, 1^6) + y\mathcal{L}_3(3; 3, 1^7)
\]
(\( y, y' \geq 0 \) and \( y + y' > 0 \)). Proceeding as above, we can prove that \( \mathcal{L}|Q_8 \) is basepoint-free, and thus that
\[
\text{Bs}(\mathcal{L}) \subset \sum_{t_{1,j} > 0} t_{1,j} \ell_{1,j}.
\]

\( \square \)

\textbf{Proof of Claim 7.1.} We know that \( \mathcal{L} \otimes \mathcal{O}_{W_r} = |dh_2 - m_1c_2 - m_2e_2 - \cdots - m_{x+1}e_{x+1}| \), and, because of Corollary 5.2, we obtain
\[
\mathcal{L} \otimes \mathcal{O}_{W_r} = |(2d - m_2)h_1 - (d + m_1 - m_2)c_1 + t_{1,2}e_2 - m_3e_3 - \cdots - m_{x+1}e_{x+1}|.
\]
So \( \mathcal{L} \otimes \mathcal{O}_{W_r} = t_{1,2} \ell_{1,2} + M \) and \( \dim(\mathcal{L} \otimes \mathcal{O}_{W_r}) = \dim(M) \), with
\[
M = \mathcal{L}_2(2d - m_2; d + m_1 - m_2, m_3, \ldots, m_{x+1}).
\]
Using the results of [Harbourne 1985], it can be checked that

\[ h^1(\mathcal{M}) = \sum_{3 \leq j \leq x+1} \left( \frac{t_{1,j}}{2} \right) \quad \text{and} \quad \text{Bs}(\mathcal{M}) = \sum_{3 \leq j \leq x+1} t_{1,j} \ell_{1,j}. \]

Let us illustrate how this is done for the case \( x = 5 \), \( t_{1,6} \geq 1 \) (the other cases are easier). First, we apply twice the (plane) Cremona transformation on \( \mathcal{M} \) as shown in the table:

<table>
<thead>
<tr>
<th>( 2d - m_2 )</th>
<th>( d + m_1 - m_2 )</th>
<th>( m_3 )</th>
<th>( m_4 )</th>
<th>( m_5 )</th>
<th>( m_6 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 3d - \sum_{i=1}^{4} m_i )</td>
<td>( 2d - m_2 - m_3 - m_4 - t_{1,4} - t_{1,3} )</td>
<td>( m_5 )</td>
<td>( m_6 )</td>
<td></td>
<td></td>
</tr>
<tr>

</table>

So, with respect to the new base \( \tilde{h}_1, \tilde{e}_1, \tilde{e}_3, \ldots, \tilde{e}_6 \), we see that \( t_{1,4} \tilde{e}_3 + t_{1,3} \tilde{e}_4 + t_{1,6} \tilde{e}_5 + t_{1,5} \tilde{e}_6 \subset \text{Bs}(\mathcal{M}) \). Going back to the original base, we obtain \( \mathcal{M} = t_{1,3}l_{1,3} + t_{1,4}l_{1,4} + t_{1,5}l_{1,5} + t_{1,6}l_{1,6} + \mathcal{M}', \) with \( \mathcal{M}' \) basepoint-free and nonspecial (see [Harbourne 1985]). Thus we get \( \text{Bs}(\mathcal{M}) = t_{1,3}l_{1,3} + t_{1,4}l_{1,4} + t_{1,5}l_{1,5} + t_{1,6}l_{1,6}, h^0(\mathcal{M}) = h^0(\mathcal{M}') \) and \( h^1(\mathcal{M}') = 0 \). A simple calculation then shows that \( h^1(\mathcal{M}) = c_2(\mathcal{M}) + \sum_{j=3}^{6} t_{i,j}^2 \), that is, \( h^1(\mathcal{M}) = \sum_{j=3}^{6} \left( \frac{t_{i,j}}{2} \right) \).

Using (7–3) we may conclude that

\[ h^1(\mathcal{L} \otimes \mathcal{O}_{W_i}) = \sum_{3 \leq j \leq x+1} \left( \frac{t_{1,j}}{2} \right) \quad \text{and} \quad \text{Bs}(\mathcal{L} \otimes \mathcal{O}_{W_i}) = \sum_{3 \leq j \leq x+1} t_{1,j} \ell_{1,j}. \]

**Proof of Claim 7.2.** If \( \mathcal{L} = \mathcal{L}_3(2; 2, 1^x) \) is in standard form, then the equality for \( h^1(\mathcal{L} \otimes \mathcal{L}_3(2; 2, 1^x)) \) follows immediately from [De Volder and Laface 2003], Theorem 5.3.

Since \( d = m_1 + m_4 - t_{1,4} \) and \( 2d \geq m_1 + m_2 + m_3 + m_4 \), we get \( m_1 \geq m_2 + 2t_{1,4} + m_3 - m_4 \geq m_2 + 2 \). Using this, it is easy to see that \( 2d - 4 \) is bigger or equal to the sum of the bigger four multiplicities unless \( \mathcal{L} = \mathcal{L}_3(m' + t; m' + 2t, m', m^6) \) for some \( m' \geq m \geq t > 0 \).

**Proof of Claim 7.3.** This follows directly from \( \tilde{\mathcal{L}} \otimes \mathcal{O}_H = \mathcal{L}_2(d - 2; m_1 - 2, m_7, m_8) \) (or \( \mathcal{L}_2(d - 2; m_1 - 2, m_7) \) if \( r = 7 \)).

**Proof of Claim 7.4.** If \( \mathcal{L} = \mathcal{L}_3(3; 3, 1^{r-1}) \) is in standard form, then the equality for \( h^1(\mathcal{L} \otimes \mathcal{L}_3(3; 3, 1^{r-1})) \) follows immediately from [De Volder and Laface 2003], Theorem 5.3.

So we only need to show that \( \mathcal{L} = \mathcal{L}_3(3; 3, 1^{r-1}) \) is in standard form; in other words, that \( m_1 - 2 \geq m_2 \). Using \( d = m_1 + m_4 - t_{1,4} \) and \( 2d \geq m_1 + m_2 + m_3 + m_4 \), we get \( m_1 \geq m_2 + 2t_{1,4} + m_3 - m_4 \geq m_2 + 2 \).
8. Proof of Theorem 6.4

Since the Cremona transformation on $X$ is nothing else than blowing-up the lines of the tetrahedron (formed by the four points used for the transformation) and blowing down the other rulings of the quadrics obtained in this way (see remark 3.4), we cannot eliminate nor construct a fixed part of dimension 2 when applying such a cubic Cremona transformation.

Since we stop applying the Cremona transformation only when we obtain something of type $\mathcal{M} + \sum m_i E_i^r$, where $m_i > 0$ and $\mathcal{M}$ is a class in standard form (that is, a class without fixed components — see Remark 6.3), we obtain precisely all fixed components of $\mathcal{L}$.

9. Proof of Theorem 6.5

Proceeding as in the proof of [De Volder and Laface 2003, Proposition 4.3], it is easy to see that $F := \sum a_i b_i^r c_i^a \in Bs(\mathcal{L})$. So, if $4d - m_1 - \cdots - m_r \neq 1$ it is enough to prove that there are no basepoints outside $F$; and if $4d - m_1 - \cdots - m_r = 1$ it is enough to prove that $Bs(\mathcal{L}) - F = mP$.

**Lemma 9.1.** Let $\mathcal{L} = \mathcal{L}_3(d; m_1, \ldots, m_r)$ be a (nonempty) class on $X$ which has no fixed components. Then $4d - m_1 - \cdots - m_r = 1$ if and only if $\mathcal{L}$ can be transformed, by a finite number of Cremona transformations, into $\mathcal{L}_3(2m; m^7, m - 1)$ for some $m > 0$.

**Proof.** Since the Cremona transformation fixes $D_{08}$ and since $Cr(\mathcal{L}). D_{08} = \mathcal{L}. D_{08}$, it is clear that $4d - m_1 - \cdots - m_r = 1$ if, after a finite number of Cremona transformations, $\mathcal{L}$ transforms into $\mathcal{L}_3(2m; m^7, m - 1)$.

Conversely, assume $4d - m_1 - \cdots - m_r = 1$. Then $\mathcal{L}$ transforms into a class $\mathcal{M} = \mathcal{L}_3(d'; m'_1, \ldots, m'_8)$ in standard form with $m_8 \geq 0$ and $\mathcal{M}. D_{08} = 4d' - m'_1 - \cdots - m'_8 = 1$, which implies that $\mathcal{M} = \mathcal{L}_3(2m; m^7, m - 1)$. □

**Lemma 9.2.** Let $\mathcal{N} := \mathcal{L}_3(d; m_1, \ldots, m_8)$ be a class in standard form on $X$, then $\mathcal{N}. \mathcal{E}_a^{b,c} \geq 0$ for all $a > 0$ and for all $b, c \in \{1, \ldots, 8\}$.

**Proof.** If $a$ is even, then $\mathcal{N}. \mathcal{E}_a^{b,c} \geq \mathcal{N}. \mathcal{E}_a^{1,2}$ for all $b, c \in \{1, \ldots, 8\}$, and $\mathcal{N}. \mathcal{E}_a^{1,2} = -\frac{1}{2}a(t_0^{1,2} + t_0^{3,4} + t_0^{5,6}) - (\frac{1}{2}a - 1)t_0^{7,8} - t_0^{1,2} + t_0^{7,8}$). Since $\mathcal{N}$ is in standard form, $0 \geq t_0^{3,4} \geq t_0^{5,6} \geq t_0^{7,8}$ and $0 \geq t_0^{1,2} + t_0^{3,4} \geq t_0^{1,2} + t_0^{7,8}$, so $\mathcal{N}. \mathcal{E}_a^{1,2} \geq 0$.

If $a$ is odd, $\mathcal{N}. \mathcal{E}_a^{b,c} \geq \mathcal{N}. \mathcal{E}_a^{7,8}$ for all $b, c \in \{1, \ldots, 8\}$, and

$$\mathcal{N}. \mathcal{E}_a^{7,8} = -\frac{1}{2}(a - 1)(t_0^{1,2} + t_0^{3,4} + t_0^{5,6} + t_0^{7,8}) - t_0^{1,2} + t_0^{3,4} + t_0^{5,6} \geq 0.$$ □

To simplify the notation, assume we want to apply the Cremona transformation using $P_1, \ldots, P_4$. 

Let $Y$ be the blowing-up of $X$ along the $\ell_{i, j}$, $1 \leq i < j \leq 4$, $p : Y \to X$ the projection map, let $E_i$, $F_i$, $E_{i, j}$ and $F_{i, j}$ be as in (3–4) and (3–5) and let $h$, $h'$, $e_i$, $f_j$, $e_{i, j}$ and $f_{i, j}$ be as in (3–7) and (3–8).

Let $p' : Y \to X'$ be the map obtained by blowing down the $F_{i, j}$.

Now, analogously to $C_{a}^{b, c}$, define $D_{a}^{b, c}$ in $A^{2}(X')$; for example, we have $D_{1}^{7, 8} = [3h' - f_1 - \cdots - f_4 - e_5 - e_6]$. Also define $s_{a}^{b, c} := - \text{Cr}(E)D_{a}^{b, c}$.

By abuse of notation, if $a > 0$ or if $a = 0$ and $\{b, c\} \subset \{1, 2, 3, 4\}$, we also denote the pullbacks of $C_{a}^{b, c}$ and $D_{a}^{b, c}$ by $C_{a}^{b, c}$ and $D_{a}^{b, c}$, respectively.

Let $F^{*}$ denote the pullback on $Y$ of $F$, and write $F^{*}$ as $F^{(1)} + F^{(2)}$, with

$$F^{(2)} = \sum_{1 \leq b < c \leq 4 \atop s_{0}^{b, c} > 0} t_{0}^{b, c}E_{b, c}.$$ 

Similarly, let $G^{*}$ denote the pullback of $G = \sum_{b, c > 0} s_{a}^{b, c}D_{a}^{b, c}$ on $Y$, and write $G^{*}$ as $G^{(1)} + G^{(2)}$, with

$$G^{(2)} = \sum_{1 \leq b < c \leq 4 \atop s_{0}^{b, c} > 0} s_{0}^{b, c}F_{b, c}.$$ 

Define $\mathcal{M} := p^{*}(\mathcal{E}) \otimes \mathcal{O}_{Y}(-F^{(2)}) \otimes \mathcal{I}_{F^{(1)}}$.

**Proposition 9.3.**

\[ \mathcal{M} = p'^{*}(\text{Cr}(\mathcal{E})) \otimes \mathcal{O}_{Y}(-G^{(2)}) \otimes \mathcal{I}_{G^{(1)}}. \]

**Proof.** First of all, by abuse of notation, let us write $\mathcal{M}$ as $\mathcal{M}^{(2)} - \mathcal{M}^{(1)}$, with

$$\mathcal{M}^{(2)} = dH - \sum_{1 \leq i \leq 8} m_{i}E_{i} - \sum_{1 \leq i < j \leq 4 \atop t_{0}^{i, j} > 0} t_{0}^{i, j}E_{i, j} \quad \text{and} \quad \mathcal{M}^{(1)} = \sum_{a > 0 \text{ or } a = 0 \text{ and } 4 < c} t_{a}^{b, c}C_{a}^{b, c}.$$ 

Using the formulas (3–5) and the fact that $s_{0}^{i, j} = d - m_{k} - m_{l} = - i_{0}^{k, l}$ with $\{i, j, k, l\} = \{1, 2, 3, 4\}$, it can easily be checked that, if $s = 2d - \sum_{i=1}^{4} m_{i}$,

$$\mathcal{M}^{(2)} = (d + s)H' - \sum_{1 \leq i \leq 4} (m_{i} + s)F_{i} - \sum_{5 \leq i \leq r} m_{i}E_{i} - \sum_{1 \leq i < j \leq 4 \atop s_{0}^{i, j} > 0} s_{0}^{i, j}F_{i, j}.$$ 

Moreover, using the formulas (3–8), a simple calculation shows that

$$\mathcal{M}^{(1)} = \sum_{a > 0 \text{ or } a = 0 \text{ and } 4 < c} s_{a}^{b, c}D_{a}^{b, c}.$$ 

Combining these two results, we obtain

$$\mathcal{M} = p'^{*}(\text{Cr}(\mathcal{E})) \otimes \mathcal{O}_{Y}(-G^{(2)}) \otimes \mathcal{I}_{G^{(1)}}. \quad \square$$
Corollary 9.4. Bs(\mathcal{L}) - F \neq \emptyset if and only if Bs(Cr(\mathcal{L})) - G \neq \emptyset.

Proof. Since the Cremona transformation is an involution, it is sufficient to prove just one implication. If P ∈ Bs(\mathcal{L}) - F then p^{-1}(P) ⊂ Bs(\mathcal{L}) - F = Bs(\mathcal{L}) - G, which implies that p'(p^{-1}(P)) ⊂ Bs(Cr(\mathcal{L})) - G (and p'(p^{-1}(P)) \neq \emptyset).

(1) If 4d - m_1 - \cdots - m_r \neq 1, we apply Cremona until we obtain a class \mathcal{L}' in standard form. Because of Corollary 9.4, it is enough to prove that Bs(\mathcal{L}') - F' = \emptyset, with F' = \sum t_i^{b,c} - \sum t_i^{b,c}C_i^{b,c}. But, because of Lemma 9.2, we have t_i^{b,c} \leq 0 if a > 0, that is, F' = \sum t_i^{b,c} - \sum t_i^{b,c}C_i^{b,c}. On the other hand, 4d - m_1 - \cdots - m_r \neq 1 implies that \mathcal{L}' is of type (1) or (4) of Theorem 6.2 (\mathcal{L}' is not of type (2) since this is a class which is invariant under Cremona, and it is not of type (3) because of Lemma 9.1).

So it follows from Theorem 6.2 that Bs(\mathcal{L}') = F', and thus Bs(\mathcal{L}') - F' = \emptyset.

(2) If 4d - m_1 - \cdots - m_r = 1, we apply Cremona until we obtain the class \mathcal{L}' = \mathcal{L}_3(2m; m^7, m - 1) (see Lemma 9.1). Reasoning as before, we get

\[ F' = \sum_{t_i^{b,c} > 0} t_i^{b,c}C_i^{b,c}, \]

but now t_0^{b,c} is equal to either 0 or -1, so F' = \emptyset. On the other hand, because of Theorem 6.2, Bs(\mathcal{L}') = mP', and, since P' is never on a strict transform of an edge of the tetrahedron used for the Cremona transformation, proceeding as in the proof of Corollary 9.4, we conclude that, on X, P' corresponds to the basepoint P of \mathcal{L}_3(2; 1^7) on D_{Q_3}. Thus Bs(\mathcal{L}) - F = mP.
