A QUANTITATIVE ESTIMATE FOR QUASIINTEGRAL POINTS IN ORBITS

LIANG-CHUNG HSIA AND JOSEPH H. SILVERMAN
A QUANTITATIVE ESTIMATE FOR QUASIINTEGRAL POINTS IN ORBITS

LIANG-CHung HSIA AND JOSEPH H. SILVERMAN

Let \( \varphi(z) \in K(z) \) be a rational function of degree \( d \geq 2 \) defined over a number field whose second iterate \( \varphi^2(z) \) is not a polynomial, and let \( \alpha \in K \). The second author previously proved that the forward orbit \( \mathcal{O}_\varphi(\alpha) \) contains only finitely many quasi-\( S \)-integral points. We give an explicit upper bound for the number of such points.

Introduction

Let \( K/\mathbb{Q} \) be a number field, let \( S \) be a finite set of places of \( K \), and let \( 1 \geq \varepsilon > 0 \). An element \( x \in K \) is said to be quasi-(\( S, \varepsilon \))-integral if

\[
\sum_{v \in S} \frac{[K_v : \mathbb{Q}_v]}{[K : \mathbb{Q}]} \log^+ |x|_v \geq \varepsilon h(x).
\]

We observe that \( x \) is in the ring of \( S \)-integers of \( K \) if and only if it is quasi-(\( S, 1 \))-integral, in which case (1) is an equality by definition of the height.

Let \( \varphi(z) \in K(z) \) be a rational function of degree \( d \geq 2 \), let \( \alpha \in K \) be a point, and let

\[
\mathcal{O}_\varphi(\alpha) = \{\alpha, \varphi(\alpha), \varphi^2(\alpha), \ldots \}
\]

denote the forward orbit of \( \alpha \) under iteration of \( \varphi \). Silverman [1993] proved that if \( \varphi^2(z) \) is not a polynomial, then the orbit \( \mathcal{O}_\varphi(\alpha) \) contains only finitely many quasi-(\( S, \varepsilon \))-integral points. More generally, if \( \#\mathcal{O}_\varphi(\alpha) = \infty \) and if \( \beta \) is not an exceptional point for \( \varphi \), then there are only finitely many \( n \geq 1 \) such that

\[
\frac{1}{\varphi^n(\alpha) - \beta}
\]

is quasi-(\( S, \varepsilon \))-integral. In this note we give an upper bound for the number of such \( n \), making explicit the dependence on \( S, \varphi, \alpha, \) and \( \beta \). More precisely, we
prove that the number of elements in the set

\[ \{ n \geq 0 : (\varphi^n(\alpha) - \beta)^{-1} \text{ is quasi-}(S, \varepsilon)\text{-integral} \} \]

is smaller than

\[ 4^\#S \gamma + \log_d \left( \frac{h(\varphi) + \hat{h}_\varphi(\beta)}{\hat{h}_\varphi(\alpha)} \right) \]

where \( \gamma \) depends only on \( d, \varepsilon, \) and \([K : \mathbb{Q}]\). (See Section 2 for the definitions of the height \( h(\varphi) \) of the map \( \varphi \) and the canonical height \( \hat{h}_\varphi \).) Our main result, Theorem 11 in Section 5, is a strengthened version of this statement.

The specific form of the upper bound in (3) is interesting, especially the dependence on the wandering point \( \alpha \) and the target point \( \beta \). For example, if \( \hat{h}_\varphi(\alpha) \) is sufficiently large (depending on \( \beta \) and \( \varphi \)), then the bound is independent of \( \alpha, \beta, \) and \( \varphi \). It is also interesting to ask whether it is possible, for a given \( \varphi \) and \( \alpha \), to make the set (2) arbitrarily large by varying \( \beta \). We discuss this question further in Remark 14.

We briefly describe the organization of the paper. We start in Section 1 by setting notation and proving an elementary estimate for the chordal metric. Section 2 is devoted to height functions, both the canonical height associated to a rational map and various results relating heights and polynomials. In Section 3, we prove a uniform version of the inverse function theorem for rational maps of degree \( d \). Section 4 states an estimate for the ramification of the iterate of a rational function, taken from [Silverman 1993; 2007], and a quantitative version of Roth’s theorem, taken from [Silverman 1987b]. In Section 5 we combine the preliminary material to prove our main theorem. Finally, in Section 6, we use the main theorem to give an explicit upper bound for the number of \( S \)-integral points in an orbit.

**Remark 1.** Silverman’s paper [1993] on finiteness of quasi-\( S \)-integral points in orbits has been used by Patrick Ingram and Silverman [2009] to prove a dynamical version of the classical Bang–Zsigmondy theorem on primitive divisors [Bang 1886; Zsigmondy 1892]. It has also been used by Felipe Voloch and Silverman [2009] to prove a local-global criterion for dynamics on \( \mathbb{P}^1 \). The quantitative results proved here should enable one to prove quantitative versions of the papers with Ingram and Voloch, but we have not included these applications in this paper in order to keep it to a manageable length.

**Remark 2.** Quantitative estimates similar to those in this paper have been proved for the number of integral points on elliptic curves and on certain other types of curves. See for example [Gross and Silverman 1995] and [Silverman 1987b].
1. Preliminary material and notation

We set the following notation:

- $K$ a number field.
- $M_K$ the set of places of $K$.
- $M_K^\infty$ the set of archimedean (infinite) places of $K$.
- $M_K^0$ the set of nonarchimedean (finite) places of $K$.
- $\log^+(x)$ the maximum of $\log(x)$ and 0. We write $\log^+_d$ for log base $d$.

For each $v \in M_K$, we let $|\cdot|_v$ denote the corresponding normalized absolute value on $K$ whose restriction to $\mathbb{Q}$ gives the usual $v$-adic absolute value on $\mathbb{Q}$. That is, if $v \in M_K^\infty$, then $|x|_v$ is the usual archimedean absolute value, and if $v \in M_K^0$, then $|x|_v = |x|_p$ is the usual $p$-adic absolute value for a unique prime $p$. We also write $K_v$ for the completion of $K$ with respect to $|\cdot|_v$, and we let $C_v$ denote the completion of an algebraic closure of $K_v$.

For each $v \in M_K$, we let $\rho_v$ denote the chordal metric defined on $\mathbb{P}^1(C_v)$, where we recall that for $[x_1, y_1]$, $[x_2, y_2]$,

$$\rho_v([x_1, y_1], [x_2, y_2]) = \begin{cases} 
\frac{|x_1 y_2 - x_2 y_1|_v}{\sqrt{|x_1|^2_v + |y_1|^2_v} \sqrt{|x_2|^2_v + |y_2|^2_v}} & \text{if } v \in M_K^\infty, \\
\frac{|x_1 y_2 - x_2 y_1|_v}{\max\{|x_1|_v, |y_1|_v\} \max\{|x_2|_v, |y_2|_v\}} & \text{if } v \in M_K^0.
\end{cases}$$

In this paper, we use the logarithmic version of the chordal metric to measure the distance between points in $\mathbb{P}^1(C_v)$.

**Definition.** The logarithmic chordal metric function

$$\lambda_v : \mathbb{P}^1(C_v) \times \mathbb{P}^1(C_v) \to \mathbb{R} \cup \{\infty\}$$

is defined by

$$\lambda_v([x_1, y_1], [x_2, y_2]) = -\log \rho_v([x_1, y_1], [x_2, y_2]).$$

Note that $\lambda_v(P, Q) \geq 0$ for all $P, Q \in \mathbb{P}^1(C_v)$, and that two points $P, Q \in \mathbb{P}^1(C_v)$ are close if and only if $\lambda_v(P, Q)$ is large. We also note that $\lambda_v$ is a particular choice of an arithmetic distance function as defined in [Silverman 1987a, Section 3], that is, it is a local height function $\lambda_{\mathbb{P}^1 \times \mathbb{P}^1, \Delta}$, where $\Delta$ is the diagonal of $\mathbb{P}^1 \times \mathbb{P}^1$.

The next lemma relates the logarithmic chordal metric $\lambda_v(x, y)$ to the usual metric $|x - y|_v$ arising from the absolute value $v$.

**Lemma 3.** Let $v \in M_K$ and let $\lambda_v$ be the logarithmic chordal metric on $\mathbb{P}^1(C_v)$. Define $\ell_v = 2$ if $v$ is archimedean, and $\ell_v = 1$ if $v$ is nonarchimedean. Then for
Let $\varphi: \mathbb{P}^1 \to \mathbb{P}^1$ be a rational map on $\mathbb{P}^1$ of degree $d \geq 2$ defined over the number field $K$. We identify $K \cup \{\infty\} \simeq \mathbb{P}^1(K)$ by fixing an affine coordinate $z$ on $\mathbb{P}^1$, so $\alpha \in K$ equals $[\alpha, 1] \in \mathbb{P}^1(K)$, and the point at infinity is $[1, 0]$. With respect to this affine coordinate, we identify rational maps $\varphi: \mathbb{P}^1 \to \mathbb{P}^1$ with rational functions $\varphi(z) \in K(z)$.

Let $P \in \mathbb{P}^1$. Then the (forward) orbit of $P$ under iteration of $\varphi$ is the set

$$\mathcal{O}_\varphi(P) = \{\varphi^n(P) : n = 0, 1, 2, \ldots\}.$$ 

The point $P$ is called a wandering point of $\varphi$ if $\mathcal{O}_\varphi(P)$ is an infinite set; otherwise $P$ is called a preperiodic point of $\varphi$. The set of preperiodic points of $\varphi$ is denoted
A QUANTITATIVE ESTIMATE FOR QUASIINTEGRAL POINTS IN ORBITS 325

by PrePer(φ). We say that a point \( A \in \mathbb{P}^1 \) is an exceptional point if it is preperiodic and \( \varphi^{-1}(\mathcal{O}_\varphi(A)) = \mathcal{O}_\varphi(A) \), which is equivalent to the assumption that the complete (forward and backward) \( \varphi \)-orbit of \( A \) is a finite set. It is a standard fact that \( A \) is an exceptional point for \( \varphi \) if and only if \( A \) is totally ramified fixed point of \( \varphi^2 \). (One direction is clear, and the other follows from the fact [Silverman 2007, Theorem 1.6] that if \( A \) is an exceptional point, then \( \mathcal{O}_\varphi(A) \) consists of at most two points.)

For a point \( P = \begin{bmatrix} x_0, x_1 \end{bmatrix} \in \mathbb{P}^1(K) \), the height of \( P \) is

\[
h(P) = \sum_{v \in M_K} \frac{[K_v : \mathbb{Q}_v]}{[K : \mathbb{Q}]} \log \max(|x_0|_v, |x_1|_v).
\]

Then the canonical height of \( P \) relative to the rational map \( \varphi \) is given by the limit

\[
\hat{h}_\varphi(P) = \lim_{n \to \infty} h(\varphi^n P)/d^n.
\]

To simplify notation, we let \( d_v = \frac{[K_v : \mathbb{Q}_v]}{[K : \mathbb{Q}]} \).

Using the definition of \( \lambda_v \), we see that

\[
h(P) = \sum_{v \in M_K} d_v \lambda_v(P, \infty) + O(1).
\]

More precisely, writing \( P = \begin{bmatrix} x_0, x_1 \end{bmatrix} \) and \( \infty = \begin{bmatrix} 1, 0 \end{bmatrix} \), we have

\[
h(P) = \sum_{v \in M_K^0} d_v \lambda_v(P, \infty) + \sum_{v \in M_K^\infty} d_v \log \left( \frac{\max(|x_0|_v, |x_1|_v)}{\sqrt{|x_0|^2_v + |x_1|^2_v}} \right).
\]

The quantity \( \max(a, b)/\sqrt{a^2 + b^2} \) is between \( 1/\sqrt{2} \) and 1 for all nonnegative \( a, b \in \mathbb{R} \), so

\[
-\frac{1}{2} \log 2 \leq h(P) - \sum_{v \in M_K} d_v \lambda_v(P, \infty) \leq 0.
\]

For further material and basic properties of height functions, see [Silverman 2007, Sections 3.1–3.5].

For a polynomial \( f = \sum a_i z^i \in K[z] \) and absolute value \( v \in M_K \), we define

\[
|f|_v = \max(|a_i|_v) \quad \text{and} \quad h(f) = h([\ldots, a_i, \ldots]) = \sum_{v \in M_K} d_v \log|f|_v.
\]

We say that a rational function \( \varphi(z) = f(z)/g(z) \in K(z) \) of degree \( d \) is written in normalized form if

\[
f(z) = \sum_{i=0}^d a_i z^i \quad \text{and} \quad g(z) = \sum_{i=0}^d b_i z^i \quad \text{with} \ a_i, b_i \in K,
\]
if \( a_d \) and \( b_d \) are not both zero, and if \( f \) and \( g \) are relatively prime in \( K[z] \). For \( v \in M_K \), we set \( |\varphi|_v = \max\{|f|_v, |g|_v\} \), and then the height of \( \varphi \) is defined by

\[
h(\varphi) = h([a_0, \ldots, a_d, b_0, \ldots, b_d]) = \sum_{v \in M_K} d_v \log |\varphi|_v.
\]

Directly from the definitions, we have

(4) \( \max(h(f), h(g)) \leq h(\varphi) \).

The following basic properties of absolute values of polynomials will be useful.

**Lemma 4.** Let \( v \in M_K \) and let \( f, g \in K[x] \) be polynomials with coefficients in \( K \).

(a) \( |f + g|_v \leq \begin{cases} |f|_v + |g|_v & \text{if } v \text{ is archimedean,} \\ \max\{|f|_v, |g|_v\} & \text{if } v \text{ is nonarchimedean.} \end{cases} \)

(b) Gauss’s lemma. If \( v \) is nonarchimedean, then \( |fg|_v = |f|_v |g|_v \).

(c) If \( v \) is archimedean and \( \deg f + \deg g < d \), then

\[
4^{-d} |fg|_v \leq |f|_v |g|_v \leq 4^d |fg|_v.
\]

**Proof.** (a) follows from the definition. For (b) and (c), see for example [Lang 1983, Chapter 3, Propositions 2.1 and 2.3]. □

**Proposition 5.** Let \( \{f_1, \ldots, f_r\} \) be a collection of polynomials in the ring \( K[x] \).

(a) \( h(f_1 f_2 \cdots f_r) \leq \sum_{i=1}^{r} (h(f_i) + (\deg f_i + 1) \log 2) \)

\[
\leq r \max_{1 \leq i \leq r} \{h(f_i) + (\deg f_i + 1) \log 2\}.
\]

(b) \( h(f_1 + f_2 + \cdots + f_r) \leq \sum_{i=1}^{r} h(f_i) + \log r \).

(c) Let \( \varphi(z), \psi(z) \in K(z) \) be rational functions. Then

\[
h(\varphi \circ \psi) \leq h(\varphi) + (\deg \varphi) h(\psi) + (\deg \varphi)(\deg \psi) \log 8.
\]

(d) Let \( \varphi(z) \in K(z) \) be a rational function of degree \( d \geq 2 \). Then for all \( n \geq 1 \), we have

\[
h(\varphi^n) \leq \left( \frac{d^n - 1}{d - 1} \right) h(\varphi) + d^2 \left( \frac{d^{n-1} - 1}{d - 1} \right) \log 8.
\]

**Proof.** The proofs of (a) and (b) can be found in [Hindry and Silverman 2000, Proposition B.7.2], where the proposition is stated for multivariable polynomials. Since we’ll use the arguments in (a) for the proof of (c), we repeat the proof of (a) for the one-variable case. (Also, our situation is slightly different from that in
[Hindry and Silverman 2000], since we are using a projective height instead of an
affine height.) Writing $f_i = \sum_{E} a_i E^X$, we have

$$f_1 \cdots f_r = \sum_{E} \left( \sum_{e_1 + \cdots + e_r = E} a_{1e_1} \cdots a_{re_r} \right) X^E,$$

and hence for $v \in M_K$,

$$|f_1 \cdots f_r|_v = \max_E \left| \sum_{e_1 + \cdots + e_r = E} a_{1e_1} \cdots a_{re_r} \right|_v$$

and $h(f_1 \cdots f_r) = \sum_{v \in M_K} d_v \log |f_1 \cdots f_r|_v$. If $v$ is nonarchimedean, then by
Gauss’s lemma, Lemma 4(b), we have

$$|f_1 \cdots f_r|_v = \prod_{i=1}^r |f_i|_v.$$

It remains to deal with an archimedean place $v$. We note that the number of
terms in the sum appearing in the right side of (5) is $(E + r - 1)_E$. Hence

$$|f_1 \cdots f_r|_v \leq \max_E \left( \binom{E + r - 1}{E} \max_{e_1 + \cdots + e_r = E} |a_{1e_1} \cdots a_{re_r}|_v \right)$$

$$\leq \max_E \left( 2^{E + r - 1} \max_{e_1 + \cdots + e_r = E} |a_{1e_1} \cdots a_{re_r}|_v \right).$$

Further, if $E > \deg(f_1 \cdots f_r)$, then the product $a_{1e_1} \cdots a_{re_r}$ is zero, since in that
case at least one of the $a_{ij}$ is zero. Hence

$$|f_1 \cdots f_r|_v \leq 2^{\deg(f_1 \cdots f_r) + r - 1} \prod_{i=1}^r |f_i|_v.$$

Let $N_v = 2^{\sum_i (\deg f_i + 1)}$ if $v$ is archimedean, and $N_v = 1$ if $v$ is nonarchimedean.
Then we compute

$$h(f_1 \cdots f_r) = \sum_{v \in M_K} d_v \log |f_1 \cdots f_r|_v$$

$$\leq \sum_{v \in M_K} d_v \left( \log N_v + \log \prod_{i=1}^r |f_i|_v \right)$$

$$\leq \sum_{i=1}^r (h(f_i) + (\deg f_i + 1) \log 2)$$

$$\leq r \max_{1 \leq i \leq r} \{ h(f_i) + (\deg f_i + 1) \log 2 \},$$

which completes the proof of (a).
Next we give a proof of (c). Write $\psi = \psi_0/\psi_1 \in K(z)$ in normalized form, so in particular $\psi_0$ and $\psi_1$ are relatively prime polynomials. Then

$$(\varphi \circ \psi)(z) = \frac{\sum a_i \psi_0^i \psi_1^{d-i}}{\sum b_i \psi_0^i \psi_1^{d-i}},$$

so by definition of the height of a rational function, we have

$$h(\varphi \circ \psi) \leq \sum_{v \in M_K} d_v \log \max \left\{ \left| \sum a_i \psi_0^i \psi_1^{d-i} \right|_v, \left| \sum b_i \psi_0^i \psi_1^{d-i} \right|_v \right\}.$$

For the right side of this inequality, if $v$ is nonarchimedean, then by Gauss’s lemma again we have

$$\left| \sum a_i \psi_0^i \psi_1^{d-i} \right|_v \leq \max \{ |f|_v |\psi_0|^i |\psi_1|^{d-i} \} \leq |\varphi|_v |\psi|_v^d.$$

Similarly,

$$\left| \sum b_i \psi_0^i \psi_1^{d-i} \right|_v \leq |\varphi|_v |\psi|_v^d.$$

Hence for $v$ nonarchimedean, $|\varphi \circ \psi|_v \leq |\varphi|_v |\psi|_v^d$.

Next let $v$ be an archimedean place of $K$. Then the triangle inequality gives

$$\left| \sum a_i \psi_0^i \psi_1^{d-i} \right|_v \leq (d + 1) |f|_v \max_i \{ |\psi_0^i \psi_1^{d-i} |_v \}. $$

Applying the estimate (6) to the product $\psi_0^i \psi_1^{d-i}$ yields

$$|\psi_0^i \psi_1^{d-i} |_v \leq 2^{d(\deg \psi + 1)} |\psi_0|^i_1 |\psi_1|^{d-i}_1 \leq 2^{d(\deg \psi + 1)} |\psi|_v^d.$$

Therefore,

$$\left| \sum a_i \psi_0^i \psi_1^{d-1} \right|_v \leq (d + 1) 2^{d(\deg \psi + 1)} |f|_v |\psi|_v^d \leq (d + 1) 2^{d(\deg \psi + 1)} |\varphi|_v |\psi|_v^d.$$

Similarly,

$$\left| \sum b_i \psi_0^i \psi_1^{d-1} \right|_v \leq (d + 1) 2^{d(\deg \psi + 1)} |\varphi|_v |\psi|_v^d.$$

We combine these estimates. To ease notation, we let $N_v = 1$ for $v$ nonarchimedean and $N_v = (d + 1) 2^{d \deg \psi} = (d + 1) 4^{\deg \psi} \deg \psi$ for $v$ archimedean. Then

$$h(\varphi \circ \psi) \leq \sum_{v \in M_K} d_v \log \max \left\{ \left| \sum a_i \psi_0^i \psi_1^{d-1} \right|_v, \left| \sum b_i \psi_0^i \psi_1^{d-1} \right|_v \right\}$$

$$\leq \sum_{v \in M_K} d_v (\log |\varphi|_v + d \log |\psi|_v + \log N_v)$$

$$\leq h(\varphi) + dh(\psi) + (\deg \varphi)(\deg \psi) \log 4 + \log (d + 1)$$

$$\leq h(\varphi) + dh(\psi) + (\deg \varphi)(\deg \psi) \log 8,$$
since \( d + 1 \leq 2^d \leq 2^{d \deg \psi} \). This completes the proof of (c).

Finally, we prove (d) by induction on \( n \). The stated inequality is clearly true for \( n = 1 \). Assume now it is true for \( n \). Then
\[
\begin{align*}
  h(\varphi^{n+1}) & \leq h(\varphi^n) + d^n h(\varphi) + d^{n+1} \log 8 \quad \text{from (c) applied to } \varphi^n \text{ and } \varphi \\
  & \leq \left( \frac{d^n - 1}{d - 1} h(\varphi) + d^2 \frac{d^{n-1} - 1}{d - 1} \log 8 \right) + d^n h(\varphi) + d^{n+1} \log 8 \\
  & \quad \text{from the induction hypothesis} \\
  & = \left( \frac{d^{n+1} - 1}{d - 1} h(\varphi) + d^2 \left( \frac{d^n - 1}{d - 1} \right) \log 8 \right) .
\end{align*}
\]

\( \square \)

The following facts about height functions are well known.

**Proposition 6.** Let \( \varphi : \mathbb{P}^1 \rightarrow \mathbb{P}^1 \) be a rational map of degree \( d \geq 2 \) defined over \( K \). There are constants \( c_1, c_2, c_3, \) and \( c_4 \), depending only on \( d \), such that the following estimates hold for all \( P \in \mathbb{P}^1(\overline{K}) \).

(a) \( |h(\varphi(P)) - d h(P)| \leq c_1 h(\varphi) + c_2 \).

(b) \( |\hat{h}_\varphi(P) - h(P)| \leq c_3 h(\varphi) + c_4 \).

(c) \( \hat{h}_\varphi(\varphi(P)) = d \hat{h}_\varphi(P) \).

(d) \( P \in \text{PrePer}(\varphi) \) if and only if \( \hat{h}_\varphi(P) = 0 \).

**Proof.** See, for example, [Hindry and Silverman 2000, Sections B.2 and B.4] or [Silverman 2007, Section 3.4]. \( \square \)

### 3. A distance estimate

Our goal in this section is a version of the inverse function theorem that gives explicit estimates for the dependence on the (local) heights of both the points and the function. It is undoubtedly possible to give a direct, albeit long and messy, proof of the desired result. We instead give a proof using universal families of maps and arithmetic distance functions. Before stating our result, we set notation for the universal family of degree \( d \) rational maps on \( \mathbb{P}^1 \).

We write \( \text{Rat}_d \subset \mathbb{P}^{2d+1} \) for the space of rational maps of degree \( d \), where we identify a rational map \( \varphi = f/g = \sum a_i z^i / \sum b_i z^i \) with the point
\[
[\varphi] = [f, g] = [a_0, \ldots, a_d, b_0, \ldots, b_d] \in \mathbb{P}^{2d+1} .
\]

If \( \varphi \in \text{Rat}_d(\overline{\mathbb{Q}}) \) is defined over \( \overline{\mathbb{Q}} \), we define the height of \( \varphi \) as in Section 2 to be the height of the associated point in \( \mathbb{P}^{2d+1}(\overline{\mathbb{Q}}) \):
\[
h(\varphi) = h([a_0, \ldots, a_d, b_0, \ldots, b_d]) .
\]

Over \( \text{Rat}_d \), there is a universal family of degree \( d \) maps, which we denote by
\[
\Psi : \mathbb{P}^1 \times \text{Rat}_d \rightarrow \mathbb{P}^1 \times \text{Rat}_d , \quad (P, \psi) \mapsto (\psi(P), \psi) .
\]
We note that $\text{Rat}_d$ is the complement in $\mathbb{P}^{2d+1}$ of a hypersurface, which we denote by $\partial\text{Rat}_d$. (The set $\partial\text{Rat}_d$ is given by the resultant $\text{Res}(f, g) = 0$, so $\partial\text{Rat}_d$ is a hypersurface of degree $2d$.) Since $\mathbb{P}^1$ is complete, we have

$$\partial(\mathbb{P}^1 \times \text{Rat}_d) = \mathbb{P}^1 \times \partial\text{Rat}_d.$$ 

The map $\Psi$ is a finite map of degree $d$. Let $R(\Psi)$ denote its ramification locus. Looking at the behavior of $\Psi$ in a neighborhood of a point $(P, \psi)$, it is easy to see that the restriction of $R(\Psi)$ to a fiber $\mathbb{P}^1_{\psi} = \mathbb{P}^1 \times \{\psi\}$ is the ramification divisor $R(\Psi)|_{\mathbb{P}^1_{\psi}} = R(\psi)$ of $\psi$. So the ramification indices of the universal map $\Psi$ and a particular map $\psi$ are related by

$$(7) \quad e(P, \psi)(\Psi) = e_P(\psi).$$

**Proposition 7.** Let $\psi \in K(z)$ be a nontrivial rational function, let $S \subset M_K$ be a finite set of absolute values on $K$, each extended in some way to $\overline{K}$, and let $A, P \in \mathbb{P}^1(K)$. Then

$$\sum_{v \in S} \max_{A' \in \psi^{-1}(A)} e_{A'}(\psi) d_v \lambda_v(P, A') \geq \sum_{v \in S} d_v \lambda_v(\psi(P), A) + O(h(A) + h(\psi) + 1),$$

where the implied constant depends only on the degree of the map $\psi$.

**Proof.** The statement and proof of Proposition 7 use the machinery of arithmetic distance functions and local height functions on quasiprojective varieties, as described in [Silverman 1987a], to which we refer for definitions, notation, and basic properties. We begin with the distribution relation for finite maps of smooth quasiprojective varieties [Silverman 1987a, Proposition 6.2(b)]. Applying this relation to the map $\Psi$ and points $x, y \in \mathbb{P}^1 \times \text{Rat}_d$ yields

$$(8) \quad \delta(\Psi(x), y; v) = \sum_{y' \in \Psi^{-1}(y)} e_{y'}(\Psi) \delta(x, y'; v) + O(\lambda_{\partial(\mathbb{P}^1 \times \text{Rat}_d)}^2(x, y; v)),$$

where $\delta(\cdot, \cdot; v)$ is a $v$-adic arithmetic distance function on $\mathbb{P}^1 \times \text{Rat}_d$, and where $\lambda_{\partial(\mathbb{P}^1 \times \text{Rat}_d)}^2$ is a local height function for the indicated divisor. In particular, if we take $x = (P, \psi)$ and $y = (A, \psi)$, then the arithmetic distance function $\delta$ and the chordal metric $\lambda_v$ defined in Section 1 satisfy

$$(9) \quad \delta(\Psi(x), y; v) = \delta(\Psi(P, \psi), (A, \psi); v) = \delta((\psi(P), \psi), (A, \psi); v) = \lambda_v(\psi(P), A).$$

Similarly, if $y' = (A', \psi) \in \Psi^{-1}(y)$, then

$$\delta(x, y'; v) = \delta((P, \psi), (A', \psi); v) = \lambda_v(P, A').$$
Further, since \( \partial(\mathbb{P}^1 \times \text{Rat}_d) = \mathbb{P}^1 \times \partial \text{Rat}_d \) is the pull-back of a divisor on \( \text{Rat}_d \) and
\[
\partial(\mathbb{P}^1 \times \text{Rat}_d)^2 = (\mathbb{P}^1 \times \partial \text{Rat}_d) \times (\mathbb{P}^1 \times \text{Rat}_d) + (\mathbb{P}^1 \times \text{Rat}_d) \times (\mathbb{P}^1 \times \partial \text{Rat}_d),
\]
applying [Silverman 1987a, Proposition 5.3(a)] gives
\[
\lambda_{\partial(\mathbb{P}^1 \times \text{Rat}_d)^2}(x, y; v) \gg \lambda_{\mathbb{P}^1 \times \partial \text{Rat}_d}((P, \psi); v) + \lambda_{\mathbb{P}^1 \times \text{Rat}_d}((A, \psi); v)
\]
(10)

Substituting (7), (9), and (10) into the distribution relation (8) yields
\[
\lambda_v(\psi(P), A) = \sum_{A' \in \psi^{-1}(A)} e_{A'}(\psi)\lambda_v(P, A') + O(\lambda_{\partial \text{Rat}_d}(\psi; v)).
\]

To ease notation, let \( A'_v \in \psi^{-1}(A) \) be a point satisfying
\[
e_{A'_v}(\psi)\lambda_v(P, A'_v) = \max_{A' \in \psi^{-1}(A)} e_{A'}\lambda_v(P, A').
\]

Then for any \( A' \in \psi^{-1}(A) \) we have
\[
e_{A'}(\psi)\lambda_v(P, A') = \min\{e_{A'_v}(\psi)\lambda_v(P, A'_v), e_{A'}(\psi)\lambda_v(P, A')\}
\]
from the choice of \( A'_v \)
\[
\leq d \min\{\lambda_v(P, A'_v), \lambda_v(P, A')\} \quad \text{since } \psi \text{ has degree } d
\]
\[
\leq d\lambda_v(A'_v, A') + O(1)
\]
from the triangle inequality.

This is a nontrivial estimate for \( A' \neq A'_v \), so in (11) we pull off the \( A'_v \) term and use (12) for the other terms to obtain
\[
\lambda_v(\psi(P), A) \leq e_{A'_v}(\psi)\lambda_v(P, A'_v) + d \sum_{\substack{A' \in \psi^{-1}(A) \\ A' \neq A'_v}} \lambda_v(A'_v, A') + O(\lambda_{\partial \text{Rat}_d}(\psi; v)).
\]

The next lemma gives an upper bound for \( \lambda_v(A'_v, A') \).

**Lemma 8.** There is a constant \( C = C(d) \) such that the following holds. Let \( \psi \in \text{Rat}_d(\overline{\mathbb{Q}}) \), let \( A \in \mathbb{P}^1(\overline{\mathbb{Q}}) \), and let \( A', A'' \in \psi^{-1}(A) \) be distinct points. Then
\[
\sum_{v \in \mathcal{M}_K} d_v \lambda_v(A', A'') \leq C(h(A) + h(\psi) + 1).
\]

**Proof.** In the notation of [Silverman 1987a], we have
\[
\lambda_v(A', A'') = \delta_{\mathbb{P}^1 \times \text{Rat}_d}((A', \psi), (A'', \psi); v)
\]
\[
= \lambda_{(\mathbb{P}^1 \times \text{Rat}_d)^2 \Delta}((A', \psi), (A'', \psi); v),
\]
where $\Delta$ is the diagonal of $(\mathbb{P}^1 \times \text{Rat}_d)^2$. Summing over $v$ gives height functions

$$
\sum_{v \in M_K} \lambda_v(A', A'') = h((\mathbb{P}^1 \times \text{Rat}_d)^2, \Delta((A', \psi), (A'', \psi))) + O(h(\mathbb{P}^1 \times \text{Rat}_d)^2((A', \psi), (A'', \psi))) + 1.
$$

Choosing an ample divisor $H$ on $\mathbb{P}^1 \times \text{Rat}_d$, we use the fact that heights with respect to a subscheme are dominated by ample heights away from the support of the subscheme [Silverman 1987a, Proposition 4.2]. (This is where we use the assumption that $A' \neq A''$, which ensures that the point $((A', \psi), (A'', \psi))$ is not on the diagonal.) This yields

$$
\sum_{v \in M_K} \lambda_v(A', A'') \ll h(\mathbb{P}^1 \times \text{Rat}_d, H(A', \psi) + h(\mathbb{P}^1 \times \text{Rat}_d, H(A'', \psi) + 1
$$

(14)

We now use [Silverman 2009, Theorem 2], which says that there are positive constants $C_1, C_2, C_3$, depending only on the degree of $\psi$, such that

$$
h(\psi(P)) \geq C_1 h(P) - C_2 h(\psi) - C_3.
$$

(15)

(The paper [Silverman 2009] deals with general rational maps $\mathbb{P}^n \dashrightarrow \mathbb{P}^n$. In our case with $n = 1$, it would be a tedious, but not difficult, calculation to give explicit values for the $C_i$, including of course $C_1 = \deg \psi$.) Applying (15) with $P = A'$ and $P = A''$, we substitute into (14) to obtain

$$
\sum_{v \in M_K} \lambda_v(A', A'') \ll h(A) + h(\psi) + 1,
$$

which completes the proof of Lemma 8.

We use Lemma 8 to bound the sum in the right side of the inequality (13). We note that $\lambda_v(A', A'') \geq 0$ for all points, so the lemma implies in particular that $\sum_{v \in S} d_v \lambda_v(A', A'') \ll h(A) + h(\psi) + 1$ for any set of places $S$. Further, the sum in (13) has at most $d - 1$ terms. Hence we obtain

$$
\sum_{v \in S} d_v \lambda_v(\psi(P), A) \leq \sum_{v \in S} e_{A_v}(\psi)d_v \lambda_v(P, A_v) + O(h(A) + h(\psi) + 1).
$$

In this inequality, the $O(h(\psi))$ term comes from two places, Lemma 8 and

$$
\sum_{v \in S} d_v \lambda_{\partial \text{Rat}_d}(\psi; v) \leq \sum_{v \in M_K} d_v \lambda_{\partial \text{Rat}_d}(\psi; v) = h_{\partial \text{Rat}_d}(\psi) = O(h(\psi) + 1),
$$

where the last equality comes from the fact that $\partial \text{Rat}_d$ is a hypersurface of degree $2d$ in $\mathbb{P}^{2d+1}$. This completes the proof of Proposition 7.
4. A ramification estimate and a quantitative version of Roth’s theorem

In this section we state two known results that will be needed to prove our main theorem. The first says that away from exceptional points, the ramification of \( \varphi^m \) tends to spread out as \( m \) increases.

**Lemma 9.** Fix an integer \( d \geq 2 \). There exist constants \( \kappa_1 \) and \( \kappa_2 < 1 \), depending only on \( d \), such that for all degree \( d \) rational maps \( \varphi : \mathbb{P}^1 \to \mathbb{P}^1 \), all points \( Q \in \mathbb{P}^1 \) that are not exceptional for \( \varphi \), all integers \( m \geq 1 \), and all \( P \in \varphi^{-m}(Q) \), we have

\[
e_P(\varphi^m) \leq \kappa_1(\kappa_2 d)^m.
\]

**Proof.** This is [Silverman 2007, Lemma 3.52]; see in particular the last paragraph of the proof. It is not difficult to give explicit values for the constants. If \( Q \) is not preperiodic, then the stronger estimate \( e_P(\varphi^m) \leq \varepsilon^{2d-2} \) is true for all \( m \). \( \square \)

The second result is the following quantitative version of Roth’s theorem.

**Theorem 10.** Let \( S \) be a finite subset of \( M_K \) that contains all infinite places. We assume that each place in \( S \) is extended to \( K \) in some fashion. Set the following notation.

- \( s \) the cardinality of \( S \).
- \( \Upsilon \) a finite, \( G_{\overline{K}/K} \)-invariant subset of \( \overline{K} \).
- \( \beta \) a map \( S \to \Upsilon \).
- \( \mu > 2 \) a constant.
- \( M \geq 0 \) a constant.

There are constants \( r_1 \) and \( r_2 \), depending only on \( [K : \mathbb{Q}], \#\Upsilon, \) and \( \mu \), such that there are at most \( 4^s r_1 \) elements \( x \in K \) satisfying both of the following conditions:

\[
\sum_{v \in S} d_v \log^+ |x - \beta_v|_v^{-1} \geq \mu h(x) - M. 
\]

\[
h(x) \geq r_2 \max_{v \in S} \{ h(\beta_v), M, 1 \}.
\]

**Proof.** This is [Silverman 1987b, Theorem 2.1], with a small change of notation. For explicit values of the constants, see [Gross 1990]. \( \square \)

5. A bound for the number of quasiintegral points in an orbit

In this section we prove our main result, which is an explicit upper bound for the number of iterates \( \varphi^n(P) \) that are close to a given base point \( A \) in any one of a fixed finite number of \( v \)-adic topologies. Here is the precise statement.

**Theorem 11.** Let \( \varphi \in K(z) \) be a rational map of degree \( d \geq 2 \). Fix a point \( A \in \mathbb{P}^1(K) \) that is not an exceptional point for \( \varphi \), and let \( P \in \mathbb{P}^1(K) \) be a wandering
point for \( \varphi \). For any finite set of places \( S \subset M_K \) and any constant \( 1 \geq \varepsilon > 0 \), define a set of nonnegative integers by

\[
\Gamma_{\varphi, S}(A, P, \varepsilon) = \{ n \geq 0 : \sum_{v \in S} d_v \lambda_v(\varphi^n P, A) \geq \varepsilon \hat{h}_\varphi(\varphi^n P) \}.
\]

(a) There exist constants

\[
\gamma_1 = \gamma_1(d, \varepsilon, [K : \mathbb{Q}]) \quad \text{and} \quad \gamma_2 = \gamma_2(d, \varepsilon, [K : \mathbb{Q}])
\]

such that

\[
\#\{ n \in \Gamma_{\varphi, S}(A, P, \varepsilon) : n > \gamma_1 + \log_d^+ \left( \frac{h(\varphi) + \hat{h}_\varphi(A)}{\hat{h}_\varphi(P)} \right) \} \leq 4^{|S|} \gamma_2.
\]

(b) In particular, there is a constant \( \gamma_3 = \gamma_3(d, \varepsilon, [K : \mathbb{Q}]) \) such that

\[
\#\Gamma_{\varphi, S}(A, P, \varepsilon) \leq 4^{|S|} \gamma_3 + \log_d^+ \left( \frac{h(\varphi) + \hat{h}_\varphi(A)}{\hat{h}_\varphi(P)} \right).
\]

(c) There is a constant \( \gamma_4 = \gamma_4(K, S, \varphi, A, \varepsilon) \) that is independent of \( P \) such that

\[
\max \Gamma_{\varphi, S}(A, P, \varepsilon) \leq \gamma_4.
\]

Before giving the proof of Theorem 11, we make a number of remarks.

**Remark 12.** Note that as a consequence of Proposition 6(d), we have \( \hat{h}_\varphi(P) > 0 \) if \( P \) is wandering point for \( \varphi \). Hence the right side of (19) is well-defined.

**Remark 13.** If we take \( \varepsilon = 1 \), then the set \( \Gamma_{\varphi, S}(A, P, \varepsilon) \) more or less coincides with the set of points in the orbit \( \mathcal{O}_\varphi(P) \) that are \( S \)-integral with respect to \( A \). We say “more or less” because \( \Gamma_{\varphi, S}(A, P, \varepsilon) \) is defined using the canonical height of \( \varphi^n(P) \), rather than the naive height. But using the inequality \( |\hat{h}_\varphi(P) - h(P)| \ll h(\varphi) + 1 \) from Proposition 6 and adjusting the constants, it is not hard to see that the estimate (19) remains true for the set

\[
\Gamma_{\varphi, S}^{\text{naive}}(A, P, \varepsilon) = \{ n \geq 0 : \sum_{v \in S} d_v \lambda_v(\varphi^n P, A) \geq \varepsilon h(\varphi^n P) \}.
\]

(See the proof of Corollary 17.) For example, taking \( A = \infty \), the set \( \Gamma_{\varphi, S}^{\text{naive}}(A, P, \varepsilon) \) consists of the points \( \varphi^n(P) \) such that \( z(\varphi^n(P)) \) is \( (S, \varepsilon_0) \)-integral for some \( \varepsilon_0 \). This is the motivation for saying that the points in \( \Gamma_{\varphi, S}(A, P, \varepsilon) \) are quasi-\((S, \varepsilon)\)-integral with respect to \( A \), where \( \varepsilon \) measures the degree of \( S \)-integrality.

**Remark 14.** The dependence of the bounds (18) and (19) on \( h(\varphi), \hat{h}_\varphi(A) \), and \( \hat{h}_\varphi(P) \) are quite interesting. A dynamical analogue of a conjecture of Lang asserts that the ratio \( h(\varphi)/\hat{h}_\varphi(P) \) is bounded, independently of \( \varphi \) and \( P \), provided that \( \varphi \) is suitably minimal with respect to \( \text{PGL}_2(K) \)-conjugation. See [Silverman 2007, Conjecture 4.98].
On the other hand, there cannot be a uniform bound for the ratio $\hat{h}_{\varphi}(A)/\hat{h}_{\varphi}(P)$, since $A$ and $P$ may be chosen arbitrarily and independent of one another. This raises the interesting question of whether the bound for $\#\Gamma_{\varphi,S}(A, P, \varepsilon)$ actually needs to depend on $A$. Even in very simple situations, it appears difficult to answer this question. For example, consider the map $\varphi(z) = z^2$, the initial point $P = 2$, and the set of primes $S = \{\infty, 3, 5\}$. As $A \in \mathbb{Q}^*$ varies, is it possible for the orbit $\mathcal{O}_\varphi(P)$ to contain more and more points that are $S$-integral with respect to $A$?

Writing $A = x/y$, we are asking if

$$\sup_{x, y \in \mathbb{Z}} \#\{(n, i, j) \in \mathbb{N}^3 : y \cdot 2^n - x = 3^i 5^j\} = \infty.$$  

**Remark 15.** We observe that $\#\Gamma_{\varphi,S}(A, P, \varepsilon)$ can grow as fast as $\log(\varepsilon^{-1})$ as $\varepsilon \to 0^+$. For example, consider the map $\varphi(z) = z^d + z^{d-1}$, the points $A = 0$ and $P = p$, and the set of primes $S = \{p\}$. Since $\varphi^n(z) = z^{(d-1)n} + \text{higher order terms}$, we have $|\varphi^n(p)|_p = p^{-(d-1)n}$, so

$$\lambda_p(\varphi^n(P), A) = \lambda_p(\varphi^n(p), 0) = -\log|\varphi^n(p)|_p = (d-1)^n \log p.$$  

Thus $\Gamma_{\varphi,S}(A, P, \varepsilon)$ consists of all $n \geq 0$ satisfying

$$(d-1)^n \log p \geq \varepsilon \hat{h}_{\varphi}(\varphi^n P) = \varepsilon d^n \hat{h}_{\varphi}(P).$$

Hence

$$\#\Gamma_{\varphi,S}(A, P, \varepsilon) = \left[ \frac{\log \left( \frac{\log p}{\varepsilon \hat{h}_{\varphi}(P)} \right)}{\log \left( \frac{d}{d-1} \right)} \right] + 1 = \frac{\log(\varepsilon^{-1})}{\log(d/(d-1))} + o(\log \varepsilon^{-1}) \quad \text{as} \quad \varepsilon \to 0^+.$$  

In particular, if $\varepsilon$ is small and $d$ is large, so $\log(d/(d-1)) \approx 1/(d-1)$, then we have

$$\#\Gamma_{\varphi,S}(A, P, \varepsilon) \approx (d-1) \log(\varepsilon^{-1}).$$

**Remark 16.** See [Gross and Silverman 1995; Silverman 1987b] for a version of Theorem 11 for elliptic curves. These papers deal with points on an elliptic curve $E$ that are quasi-$(S, \varepsilon)$-integral with respect to $O$, the zero point of $E$. It is also of interest to study points that are integral with respect to some other point $A$, and in particular to see how the bound depends on $A$. The distance function on $E$ is translation invariant up to $O(h(E))$, so we want to estimate the size of the set

$$(20) \{ P \in E(K) : \sum_{v \in S} d_v \lambda_v(P - A) \geq \varepsilon \hat{h}_E(P) \}.$$  

Translating the points in (20) by $A$, we want to count points satisfying $\sum d_v \lambda_v(P) \geq \varepsilon \hat{h}_E(P + A) + O(h(E))$. The canonical height on an elliptic curve is a quadratic form, so $\hat{h}_E(P + A) \leq 2\hat{h}_E(P) + 2\hat{h}_E(A)$. Using the results in [Silverman 1987b],
this leads to a bound for the set (20) in which the dependence on $A$ appears as the ratio $\hat{h}_E(A)/\hat{h}_E(P_{\text{min}})$, where $P_{\text{min}}$ is the point of smallest nonzero height in $E(K)$. This is analogous to the dependence on $A$ in (19).

Proof of Theorem 11. For brevity, we will write $\Gamma_S(\varepsilon)$ in place of $\Gamma_{\varphi,S}(A, P, \varepsilon)$. For the given $\varepsilon$, we set $m \geq 1$ to be the smallest integer satisfying $\kappa_1^4 \leq \varepsilon/5\kappa_2$, where $\kappa_1$ and $\kappa_2$ are the positive constants appearing in Lemma 9. Since $\kappa_2 < 1$, there exists such an integer $m$. Notice that $\kappa_1$ and $\kappa_2$ depend only on $d$; consequently $m$ depends only on $d$ and $\varepsilon$. More precisely, if we assume (without loss of generality) that $\varepsilon < 1/2$, then $m \ll \log(\varepsilon^{-1})$, where the implied constant depends only on $d$.

Put 

$$e_m = \max_{A' \in \varphi^{-m}(A)} e_{A'}(\varphi^m).$$

Then Lemma 9 and our choice of $m$ imply that

$$e_m \leq \kappa_1(\kappa_2 d)^m \leq \varepsilon d^m/5.$$

Further, Proposition 7 says that for all $Q \in \mathbb{P}^1(K)$ we have

$$e_m \sum_{v \in S} \max_{A' \in \varphi^{-m}(A)} d_v \lambda_v(Q, A') \geq \sum_{v \in S} d_v \lambda_v(\varphi^m Q, A) - O(h(A) + h(\varphi^m) + 1),$$

where the implied constant depends on $\deg(\varphi^m)$.

Suppose first that $n \leq m$ for all $n \in \Gamma_S(\varepsilon)$. Then clearly $\#\Gamma_S(\varepsilon) \leq m$, and from our choice of $m$ we have

$$\#\Gamma_S(\varepsilon) \leq m \leq \frac{\log(5\kappa_1) + \log(\varepsilon^{-1})}{\log(\kappa_2^{-1})} + 1.$$

This upper bound has the desired form, since $\kappa_1 > 0$ and $1 > \kappa_2 > 0$ depend only on $d$.

We may thus assume that there exists an $n \in \Gamma_S(\varepsilon)$ such that $n > m$, and we fix such an $n$. By the definition of $\Gamma_S(\varepsilon)$ we have

$$\varepsilon \hat{h}_E(\varphi^n P) \leq \sum_{v \in S} d_v \lambda_v(\varphi^n P, A).$$

Applying (22) to the point $Q = \varphi^{n-m}(P)$ yields

$$\varepsilon \hat{h}_E(\varphi^n P) \leq e_m \sum_{v \in S} d_v \max_{A' \in \varphi^{-m}(A)} \lambda_v(\varphi^{n-m} P, A') + O(h(A) + h(\varphi^m) + 1),$$

where the big-$O$ constant depends on $\deg \varphi^m = d^m$, and so on $d$ and $\varepsilon$.

For each $v \in S$ we choose an $A'_v \in \varphi^{-m}(A)$ satisfying

$$\lambda_v(\varphi^{n-m} P, A'_v) = \max_{A' \in \varphi^{-m}A} \lambda_v(\varphi^{n-m} P, A').$$
(For ease of exposition, we will assume that \( z(A') \neq \infty \) for all \( A' \in \varphi^{-m}A \). If this is not the case, then we use \( z \) for some of the \( A' \), and we use \( z^{-1} \) for the others.)

Let \( S' \subset S \) be the set of places in \( S \) defined by

\[
S' = \{ v \in S : \lambda_v(\varphi^{n-m}(P), A'_v) > \lambda_v(A'_v, \infty) + \log \ell_v \},
\]

where we recall that \( \ell_v = 2 \) if \( v \) is archimedean and \( \ell_v = 1 \) otherwise. Set \( S'' = S \setminus S' \). Applying Lemma 3 to the places in \( S' \) and using the definition of \( S'' \) for the places in \( S'' \), we find that

\[
\varepsilon \hat{h}_\varphi(\varphi^n(P)) \\
\leq \left( \sum_{v \in S'} + \sum_{v \in S''} \right) d_v \lambda_v(\varphi^n P, A) \quad \text{since } n \in \Gamma_S(A, P, \varepsilon) \\
\leq e_m \left( \sum_{v \in S'} + \sum_{v \in S''} \right) d_v \lambda_v(\varphi^{n-m}(P), A'_v) + O(h(A) + h(\varphi^m) + 1) \quad \text{from the definition of } A'_v \text{ and (23)} \\
\leq e_m \sum_{v \in S'} d_v (2\lambda_v(A'_v, \infty) - \log|z(\varphi^{n-m}(P)) - z(A'_v)| + \log \ell_v) \\
\quad + e_m \sum_{v \in S''} d_v (\lambda_v(A'_v, \infty) + \log \ell_v) + O(h(A) + h(\varphi^m) + 1) \quad \text{from Lemma 3} \\
\leq e_m \sum_{v \in S'} d_v \log|z(\varphi^{n-m}(P)) - z(A'_v)|^{-1} \\
\quad + e_m \sum_{v \in S'} d_v (2\lambda_v(A'_v, \infty) + \log \ell_v) + O(h(A) + h(\varphi^m) + 1).
\]

We now use (b) and (c) of Proposition 6 to observe that

\[
\sum_{v \in S} d_v \lambda_v(A'_v, \infty) \leq \sum_{A' \in \varphi^{-m}(A)} \sum_{v \in S} d_v \lambda_v(A', \infty) \leq \sum_{A' \in \varphi^{-m}(A)} h(A') \\
\leq \sum_{A' \in \varphi^{-m}(A)} (\hat{h}_\varphi(A') + O(h(\varphi) + 1)) \\
\leq \hat{h}_\varphi(A) + O(h(\varphi) + 1),
\]

Here the last line follows because there are at most \( d^m \) terms in the sum, and \( \hat{h}_\varphi(A') = d^{-m} \hat{h}_\varphi(A) \). The constants depend only on \( m \) and \( d \), and so on \( \varepsilon \) and \( d \). Further, from the definition of \( \ell_v \), we have

\[
\sum_{v \in S} d_v \log \ell_v \leq \log 2.
\]
We also note from Proposition 5(d) that \( h(\varphi^m) \ll h(\varphi) + 1 \), with the implied constant depending only on \( d \) and \( m \). Hence

\[
\varepsilon \hat{h}_\varphi(\varphi^n(P)) \leq e_m \sum_{v \in S'} d_v \log^+ |z(\varphi^{n-m}(P)) - z(A'_v)|^{-1} + O(\hat{h}_\varphi(A) + h(\varphi) + 1).
\]

We are going to apply Roth’s theorem (Theorem 10) to the set

\[
\Upsilon = \{z(A') : A' \in \varphi^{-m}(A)\} \subset \bar{K},
\]

the map \( \beta : S' \to \Upsilon \) given by \( \beta_v = A'_v \), and the points \( x = \varphi^{n-m}(P) \) for \( n \in \Gamma_\zeta(\varepsilon) \).

We note that \( \Upsilon \) is a \( G_{\bar{K}/K} \)-invariant set and that \( \#\Upsilon \leq d^m \). We apply Theorem 10 to the set of places \( S' \), taking \( M = 0 \) and \( \mu = 5/2 \). This gives constants \( r_1 \) and \( r_2 \), depending only on \([K : \mathbb{Q}], d, \) and \( \varepsilon \), such that the set of \( n \in \Gamma_\zeta(\varepsilon) \) with \( n > m \) can be written as a union

\[
\{n \in \Gamma_\zeta(\varepsilon) : n > m\} = T_1 \cup T_2 \cup T_3,
\]

whose three sets are characterized as follows:

\[
\begin{align*}
\#T_1 &\leq 4^{#S'} r_1, \\
T_2 &\{n > m : \sum_{v \in S'} d_v \log^+ |z(\varphi^{n-m}(P)) - z(A'_v)|^{-1} \leq \frac{5}{2} h(\varphi^{n-m}(P))\}, \\
T_3 &\{n > m : h(\varphi^{n-m}(P)) \leq r_2 \max_{v \in S'} \{h(A'_v), 1\}\}.
\end{align*}
\]

We already have a bound for the size of \( T_1 \), so we look at \( T_2 \) and \( T_3 \). We start with \( T_3 \) and use (b) and (c) of Proposition 6 to estimate

\[
\begin{align*}
h(A'_v) &\leq \hat{h}_\varphi(A') + c_3 h(\varphi) + c_4 \\
&= d^{-m} \hat{h}_\varphi(A) + c_3 h(\varphi) + c_4,
\end{align*}
\]

\[
\begin{align*}
h(\varphi^{n-m}(P)) &\geq \hat{h}_\varphi(\varphi^{n-m}(P)) - c_3 h(\varphi) - c_4 \\
&= d^{-m} \hat{h}_\varphi(P) - c_3 h(\varphi) - c_4.
\end{align*}
\]

Hence

\[
T_3 \subset \{n > m : d^{-m} \hat{h}_\varphi(P) \leq c_5 \hat{h}_\varphi(A) + c_6 h(\varphi) + c_7\},
\]

so every \( n \in T_3 \) satisfies

\[
n \leq m + \log^+_d \left( \frac{c_5 \hat{h}_\varphi(A) + c_6 h(\varphi) + c_7}{\hat{h}_\varphi(P)} \right)
\]

\[
\leq c_8 + \log^+_d \left( \frac{\hat{h}_\varphi(A) + h(\varphi)}{\hat{h}_\varphi(P)} \right).
\]
Finally, we consider the set $T_2$. Again using (b) and (c) of Proposition 6 to relate $h(\varphi^{n-m}(P))$ to $d^{n-m}\hat{h}_\varphi(P)$, we find that every $n \in T_2$ satisfies
\[
\sum_{v \in S'} d_v \log^+ |z(\varphi^{n-m}(P)) - z(A'_v)|^{-1} \leq \frac{5}{2} d^{n-m} \hat{h}_\varphi(P) + c_3 h(\varphi) + c_4.
\]

We substitute this estimate into (24) to obtain
\[
\varepsilon \hat{h}_\varphi(\varphi^n(P)) \leq e_m \frac{5}{2} d^{n-m} \hat{h}_\varphi(P) + c_9 (\hat{h}_\varphi(A) + h(\varphi) + 1).
\]

We know from (21) that $e_m \leq \varepsilon d^m / 5$, and also $\hat{h}_\varphi(\varphi^n(P)) = d^n \hat{h}_\varphi(P)$, which yields
\[
\varepsilon d^n \hat{h}_\varphi(P) \leq \left( \frac{\varepsilon}{5} d^m \right) \frac{5}{2} d^{n-m} \hat{h}_\varphi(P) + c_9 (\hat{h}_\varphi(A) + h(\varphi) + 1).
\]

A little bit of algebra gives the inequality
\[
\varepsilon \hat{h}_\varphi(\varphi^n(P)) \leq e_m \frac{5}{2} d^{n-m} \hat{h}_\varphi(P) + c_9 (\hat{h}_\varphi(A) + h(\varphi) + 1).
\]

Combining the estimate for $\#T_1$ with the bounds (25) and (26) for the largest elements in $T_2$ and $T_3$ completes the proof of (a).

We note that (b) follows immediately from (a).

Finally, we prove (c). Our first observation is that the set $\Upsilon = z(\varphi^{-m}(A))$ used in the application of Roth’s theorem does not depend on the point $P$. So the largest element in the finite set $T_1$ is bounded independently of $P$. (Of course, since Roth’s theorem is not effective, we do not have an explicit bound for max $\Upsilon$ in terms $K, S, \varepsilon, \varphi$ and $A$, but that is not relevant.)

Our second observation is to note that the quantity
\[
\hat{h}_{\min, K} = \inf \{ \hat{h}_\varphi(P) : P \in \mathbb{P}^1(K) \text{ wandering for } \varphi \}
\]
is strictly positive. To see this, let $P_0 \in \mathbb{P}^1(K)$ be any $\varphi$-wandering point. Then
\[
\hat{h}_{\min, K} = \inf \{ \hat{h}_\varphi(P) : P \in \mathbb{P}^1(K) \text{ and } 0 < \hat{h}_\varphi(P) \leq \hat{h}_\varphi(P_0) \}.
\]

This last set is finite, so the infimum is over a finite set of positive numbers, and hence is strictly positive. Therefore in the upper bounds (25) and (26) for max $T_2$ and max $T_3$, we may replace $\hat{h}_\varphi(P)$ with $\hat{h}_{\min, K}$ to get upper bounds independent of $P$. This proves that max$(T_1 \cup T_2 \cup T_3)$ may be bounded independently of $P$, which completes the proof of (c).
6. A bound for the number of integral points in an orbit

In this section, we use Theorem 11 to give a uniform upper bound for the number of S-integral points in an orbit.

**Corollary 17.** Let $K$ be a number field, let $S \subset M_K$ be a finite set of places that includes all archimedean places, let $R_S$ be the ring of S-integers of $K$, and let $d \geq 2$. There is a constant $\gamma = \gamma(d, [K : \mathbb{Q}])$ such that for all rational maps $\varphi \in K(z)$ of degree $d$ satisfying $\varphi^2(z) \notin K[z]$ and all $\varphi$-wandering points $P \in \mathbb{P}^1(K)$, the number of $S$-integral points in the orbit of $P$ is bounded by

$$\# \{ n \geq 1 : z(\varphi^n(P)) \in R_S \} \leq 4^{#S} \gamma + \log d \left( \frac{h(\varphi)}{\hat{h}_\varphi(P)} \right).$$

**Proof.** By definition, an element $\alpha \in K$ is in $R_S$ if and only if $|\alpha|_v \leq 1$ for all $v \not\in S$, or equivalently, if and only if

$$h(\alpha) = \sum_{v \in S} d_v \log \max(|\alpha|_v, 1).$$

We note that for $v \in M_K^0$ we have

$$\lambda_v(\alpha, \infty) = \lambda_v([\alpha, 1], [1, 0]) = \log \max(|\alpha|_v, 1).$$

The formula for $\lambda_v$ when $v$ is archimedean is slightly different, but the trivial inequality $\max\{t, 1\} \leq \sqrt{t^2 + 1}$ shows that for $v \in M_K^\infty$ we have

$$\log \max(|\alpha|_v, 1) \leq \lambda_v(\alpha, \infty).$$

Hence $\alpha \in R_S$ implies $h(\alpha) \leq \sum_{v \in S} d_v \lambda_v(\alpha, \infty)$.

Let $n \geq 1$ satisfy $z(\varphi^n(P)) \in R_S$. Then

$$h(\varphi^n(P)) \leq \sum_{v \in S} d_v \lambda_v(\varphi^n(P), \infty).$$

Proposition 6 tells us that

$$h(\varphi^n(P)) \geq \hat{h}_\varphi(\varphi^n(P)) - c_3 h(\varphi) - c_4 = d^n \hat{h}_\varphi(P) - c_3 h(\varphi) - c_4,$$

where $c_3$ and $c_4$ depend only on $d$. Combining (27) and (28) gives

$$\sum_{v \in S} d_v \lambda_v(\varphi^n(P), \infty) \geq d^n \hat{h}_\varphi(P) - c_3 h(\varphi) - c_4.$$

We consider two cases. First, if

$$d^n \hat{h}_\varphi(P) \leq 2c_3 h(\varphi) + 2c_4,$$
then the number of possible values of $n$ is at most

$$\log_d^+ \left( \frac{2c_3 h(\varphi) + 2c_4}{\hat{h}_\varphi(P)} \right),$$

which has the desired form. Second, if

$$d^n \hat{h}_\varphi(P) \geq 2c_3 h(\varphi) + 2c_4,$$

then (29) implies that

$$(30) \sum_{v \in S} d_v \lambda_v (\varphi^n(P), \infty) \geq \frac{1}{2} d^n \hat{h}_\varphi(P) = \frac{1}{2} \hat{h}_\varphi(\varphi^n(P)).$$

Now Theorem 11(b) with $\varepsilon = 1/2$ and $A = \infty$ tells us that the number of $n$ satisfying (30) is at most

$$(31) 4^{\#S} \gamma_3 + \log_d^+ \left( \frac{h(\varphi) + \hat{h}_\varphi(\infty)}{\hat{h}_\varphi(P)} \right),$$

where $\gamma_3$ depends only on $[K : \mathbb{Q}]$ and $d$. (Note that our assumption that $\varphi^2(z)$ is not a polynomial is equivalent to the assertion that $\infty$ is not an exceptional point for $\varphi$. This is needed in order to apply Theorem 11.) It only remains to observe that

$$\hat{h}_\varphi(\infty) \leq h(\infty) + c_3 h(\varphi) + c_4 \quad \text{and} \quad h(\infty) = h([0, 1]) = 0$$

to see that the bound (31) has the desired form. \hfill \square
