MAHLO CARDINALS AND THE TORSION PRODUCT OF PRIMARY ABELIAN GROUPS

PATRICK W. KEEF

Nunke’s problem asks when the torsion product of two abelian \(p\)-groups is isomorphic to a direct sum of cyclic groups. A complete solution to the problem is given using a new invariant, denoted by \(L_G\), whose values are certain collections of finite sets of uncountable regular cardinals. This is a refinement of a previous approach to the problem that only worked up to the first cardinal that is weakly Mahlo. The multiplicative properties of \(L_G\) are then related to the generalized continuum hypothesis.

Introduction and terminology

A fundamental question of Nunke asks when the torsion product of two abelian \(p\)-groups is isomorphic to a direct sum of cyclic groups. Early work on the problem included [Hill 1983b; Keef 1988; 1990; 1991; 1993; Nunke 1964; 1967a; 1967b]. More recently, the paper [Keef 2008] presented a new approach that unfortunately had two drawbacks: it was rather complicated, and it only worked for groups whose cardinality did not exceed the first regular limit cardinal. Still more recently, in [Balof and Keef 2009] a second approach was presented. This refinement was more straightforward and also had the advantage of working up to the first weakly Mahlo cardinal, which is substantially larger than the first regular limit cardinal. (The definitions of these terms will be reviewed later.) The purpose of this paper is to give a complete solution to Nunke’s problem. In so doing, we will show that the limitations of the techniques of [Balof and Keef 2009] are unavoidable.

We stress that, except where explicitly stated, the results in this paper are valid in ZFC; that is, they do not depend upon special set-theoretic assumptions such as the axiom of constructibility (\(V = L\)) or the generalized continuum hypothesis (GCH).

To begin, by the term “group” we will mean an abelian \(p\)-group, where \(p\) is a fixed prime. Our terminology and notation will generally follow [Fuchs 1970; 1973], and we will on occasion refer the reader to [Eklof and Mekler 2002] or [Jech 2003] for set-theoretic material. A group will be said to be \(\Sigma\)-cyclic if it is isomorphic to a direct sum of cyclic groups. We will denote the torsion product of the groups \(G\)

MSC2010: 20K10, 20K40.

Keywords: primary abelian group, Mahlo cardinals, torsion product.
and $H$ by the (admittedly nonstandard) $G \vartriangleleft H$. This notation is considerably more compact than the usual $\text{Tor}(G, H)$ and will make our computations significantly clearer.

To answer Nunke’s problem we need to find an invariant that gives positive answers to the following two questions:

(N1) Does this invariant tell us when a group is $\Sigma$-cyclic?

(N2) Does this invariant behave well with respect to the torsion product?

Before describing two such possible invariants, which we designate by $K_G$ and $L_G$, we first introduce some set-theoretic terminology.

Suppose $\mathcal{H}$ is the class of uncountable regular cardinals, and let $\mathcal{H}_f$ denote the class of finite subsets of $\mathcal{H}$. By a $\mathcal{H}_f$-antichain we mean a set $M$ of finite subsets of $\mathcal{H}$ (that is, a subset of $\mathcal{H}_f$) such that whenever $S, T \in M$ and $S \subseteq T$, then $S = T$. Given an $\mathcal{H}_f$-antichain $M$, let $\mathcal{H}_{\mathcal{A}}$ be the class of all $T \in \mathcal{H}_f$ such that $S \subseteq T$ for some $S \in M$. We call such a class an $\mathcal{H}_f$-invariant and we say $M$ generates $\mathcal{H}_{\mathcal{A}}$. Note that if $\mathcal{H}_{\mathcal{A}}$ is an $\mathcal{H}_f$-invariant, then the set of minimal elements of $\mathcal{H}_{\mathcal{A}}$ under the inclusion ordering is precisely $M$, and if $S \in \mathcal{A}$ and $S \subseteq T \in \mathcal{H}_f$, then $T \in \mathcal{A}$. In other words, $\mathcal{H}_f$-antichains and $\mathcal{H}_f$-invariants are two terms for essentially the same phenomenon.

What we have just defined as an $\mathcal{H}_f$-invariant was called an $\mathcal{H}_K$-invariant in [Balof and Keef 2009]. The reason for the difference is that we define below another $\mathcal{H}_f$-invariant, $L_G$, in addition to the $\mathcal{H}_f$-invariant $K_G$ from the earlier work.

We now point out two special, and extreme, cases of the above notions. Clearly, $0_\mathcal{H} := \varnothing$ is the $\mathcal{H}_f$-invariant generated by $M = \varnothing$, and $1_\mathcal{H} := \mathcal{H}_f$ is the $\mathcal{H}_f$-invariant generated by $M = \{\varnothing\}$. Inclusion, $\subseteq$, is clearly reflexive, antisymmetric and transitive on $\mathcal{H}_f$-invariants; and under this ordering, $0_\mathcal{H}$ and $1_\mathcal{H}$ are the least and greatest $\mathcal{H}_f$-invariants, respectively.

If $\kappa$ is a regular uncountable cardinal, then $C \subseteq \kappa$ is a CUB if it is closed and unbounded in the order topology; $W \subseteq \kappa$ is stationary if $W \cap C \neq \varnothing$ for all CUB subsets $C \subseteq \kappa$. Further, $\kappa$ is weakly Mahlo if $\kappa \cap \mathcal{R} = \{\tau < \kappa : \tau \in \mathcal{R}\}$ is stationary in $\kappa$. Let $\mathcal{M}$ denote the class of all weakly Mahlo cardinals; if $\mathcal{M}$ is nonempty, let $\delta_m$ be its smallest element, and otherwise, let $\delta_m = \infty$. A regular cardinal $\kappa$ is Mahlo if it is weakly Mahlo and strongly inaccessible (that is, $\gamma < \kappa$ implies $2^{\|\gamma\|} < \kappa$). Clearly, in the context of the generalized continuum hypothesis (GCH), every weakly Mahlo cardinal is, in fact, Mahlo.

Consider first the degree to which $K_G$ answered question (N1).

**Theorem 0.1** [Balof and Keef 2009, Theorems 3(b) and 6]. Suppose $G$ is a group.

(a) If $G$ is $\Sigma$-cyclic, then $K_G = 0_\mathcal{H}$.

(b) If $K_G = 0_\mathcal{H}$ and the final rank of $G$ is strictly less than $\delta_m$, then $G$ is $\Sigma$-cyclic.
So, at least for groups of cardinality less than $\delta_m$, $K_G$ can be used to characterize when they are direct sums of cyclics. One of our goals is to show that the cardinality restriction in Theorem 0.1 is truly necessary. In our first main result, Theorem 1.2, we show that in the context of the constructible universe ($V = L$), if there is a (weakly) Mahlo cardinal, then there is, in fact, a group $G$ such that $K_G = 0$ that is not $\Sigma$-cyclic.

On the other hand, our new $R_f$-invariant $L_G$ will be much better at answering question (N1). In Theorem 1.6, we show that for any group of whatever cardinality, $G$ is $\Sigma$-cyclic if and only if $L_G = 0$. So, when it comes to the first of the two questions, $L_G$ is a definite improvement over $K_G$.

We now consider the second question, (N2). If $A$ and $B$ are $R_f$-invariants, define

$$A \cdot B = \{ S \cup T : S \in A, T \in B, S \cap T = \emptyset \}.$$ 

Clearly, this very natural product is associative and commutative, $0 \cdot A = 0$ and $1 \cdot A = A$. The following result states that $K_G$ answered (N2) perfectly.

**Theorem 0.2** [Balof and Keef 2009, Theorem 4]. If $G$ and $H$ are any two groups, then

$$K_{G \uplus H} = K_G \cdot K_H.$$ 

The obvious question is whether $L_{G \uplus H}$ also always agrees with $L_G \cdot L_H$. We do verify that this is the case in the situation of relevance to Nunke’s problem. In Theorem 2.2 we show that $G \uplus H$ is $\Sigma$-cyclic if and only if $L_{G \uplus H} = 0$ if and only if $L_G \cdot L_H = 0$. Again, this is a theorem in ZFC; it means that $G \uplus H$ is $\Sigma$-cyclic if and only if for every $S \in L_G$ and $T \in L_H$, the intersection $S \cap T$ is nonempty. In particular, in some sense, the invariant $L_G$ is sufficient to “solve” Nunke’s problem. However, as will be seen, calculating $L_G$, even for some very familiar groups, quickly involves undecidable questions of cardinal arithmetic.

Next, we show that the full statement that $L_{G \uplus H} = L_G \cdot L_H$ is true for all $G$ and $H$ cannot be decided in ZFC. This statement does follow from GCH (Corollary 2.4). However, if it is consistent with ZFC that there is a weakly Mahlo cardinal, then it is consistent with ZFC that there are groups $G$ and $H$ for which it fails (Corollary 3.5). Surprisingly, this example is simply where $G$ and $H$ are copies of the standard torsion-complete group $B$, where $B = \bigoplus_{n < \omega} \mathbb{Z}/p^n$. This dramatically illustrates the point that computing $K_G$ or $L_G$, even for well-known groups such as $B$, can depend upon questions of set theory and cardinal arithmetic.

Although the solution to Nunke’s problem does necessitate going from the invariant $K_G$ to the new invariant $L_G$, it is not true that $L_G$ is in all ways superior to $K_G$. We have already noted that it is undecidable if Theorem 0.2 can be generalized to $L_G$. In addition, by [Balof and Keef 2009, Theorem 3(a)], $K_G$ behaves very
nicely with respect to direct sums. In Theorem 3.6 we show that the same holds for $L_G$ if and only if there are no weakly Mahlo cardinals.

We close the paper by noting a few of the results from [Balof and Keef 2009] that we can generalize to groups of arbitrary cardinality using $L_G$. For example, in Theorem 3.8 we show that a group $G$ is a “$\nabla$-zero divisor” (that is, there is a group $H$ which is not $\Sigma$-cyclic such that $G \nabla H$ is $\Sigma$-cyclic) if and only if it is “$\nabla$-nilpotent” (that is, for some positive integer $n$, $G^n = G \nabla G \nabla \cdots \nabla G$ is $\Sigma$-cyclic); in [Balof and Keef 2009] we were only able to verify this for groups of cardinality less than $\delta_m$.

1. The first question: $K_G$, $L_G$ and $\Sigma$-cyclic groups

We begin with a few elementary definitions regarding elements of $\mathcal{R}_f$. If $T \in \mathcal{R}_f$, let $\nu(T)$ be the number of elements in $T$, so $\nu(T)$ is a nonnegative integer. In addition, let $\mu(\varnothing) = \aleph_0$, and if $T$ is nonempty, let $\mu(T)$ be its largest element; further, let $T' = T - \{\mu(T)\}$.

We now review the definition of $K_G$ given in [Balof and Keef 2009]. The following formulation is clearly equivalent to that given in the earlier work, but it will be more convenient for our purposes, especially when we want to introduce $L_G$. Given $T \in \mathcal{R}_f$, we answer the question of whether to place it in $K_G$ by a traditional induction on $\nu(T)$. First, the base case:

(K0) If $\nu(T) = 0$ (that is, $T = \varnothing$), then $T \in K_G$ if and only if $p^{\omega}G \neq \{0\}$.

Next, suppose $n$ is a positive integer and for all groups $H$ and all $S \in \mathcal{R}_f$ with $\nu(S) < n$ we have defined when $S \in K_H$. Let $T \in \mathcal{R}_f$ have $n$ elements; note that since $\nu(T') = n - 1$, for all groups $H$ we have already answered the question of when $T' \in K_H$. We now let $T \in K_G$ if and only if either

(K1) $T' \in K_G$, or

(K2) $G$ has a subgroup $A$ of cardinality $\kappa := \mu(T) \in \mathcal{R}$ with a filtration $\mathcal{A} = \{A_i\}_{i < \kappa}$ such that

$$\Gamma_{T'}(A) := \{ i < \kappa : T' \in K_{A/A_i} \}$$

is stationary in $\kappa$.

Recall that to say $\mathcal{A} = \{A_i\}_{i < \kappa}$ is a filtration of $A$ means that it is a smoothly ascending chain of subgroups, its union is all of $A$ and each $A_i$ has cardinality less than $\kappa$. In (K2) we are only concerned with whether $\Gamma_{T'}(A)$ is stationary in $\kappa$. If $\mathcal{A}'$ is another filtration of $A$, it follows that $\mathcal{A}$ and $\mathcal{A}'$ will agree on a CUB subset of $\kappa$ so that the property that $\Gamma_{T'}(A)$ is stationary does not depend upon which filtration is chosen. As a result, we will often, without extensive comment, replace one filtration by another, e.g., one composed of pure subgroups.
We now review a useful realization theorem from [Balof and Keef 2009]. If \( \kappa \) is a cardinal, then a group \( G \) is said to be \( \kappa\)-\( \Sigma \)-cyclic if all its subgroups of cardinality strictly less than \( \kappa \) are \( \Sigma \)-cyclic. If \( T \in \mathcal{R}_f \), then the \( \mathcal{R}_f \)-invariant generated by the antichain \{\( T \)\} is called \( T \)-principal.

**Lemma 1.1** [Balof and Keef 2009, Lemma 9]. (\( V = L \)) Suppose that \( T \in \mathcal{R}_f \), \( T \cap \mathcal{M} = \emptyset \) and \( \kappa = \mu(T) \). Assuming the axiom of constructibility, there is a \( \kappa\)-\( \Sigma \)-cyclic group \( G \) of cardinality \( \kappa \) such that \( K_G \) is \( T \)-principal.

The following shows that \( K_G \) is inherently limited with respect to answering question (N1):

**Theorem 1.2.** Assuming the axiom of constructibility, there is a group \( G \) which is not \( \Sigma \)-cyclic such that \( K_G = 0_{\mathfrak{R}} \) if and only if there exists a weakly Mahlo cardinal.

**Proof.** Certainly, if there are no weakly Mahlo cardinals, then \( \delta_m = \infty \) and the result follows from Theorem 0.1. (Note that this direction does not use \( V = L \).) Suppose, then, that \( \delta_m < \infty \). Let \( \mathcal{R}_m = \mathcal{R} \cap \delta_m \), so \( \mathcal{R}_m \) is stationary in \( \delta_m \). If \( \kappa \in \mathcal{R}_m \), let \( T \in \mathcal{R}_f \) be chosen so that \( T \subseteq \mathcal{R} - \mathcal{M} \) and \( \mu(T) = \kappa \) (e.g., \( T = \{ \kappa \} \)) and \( G_\kappa \) be a group defined as in Lemma 1.1 so that \( K_{G_\kappa} \) is \( T \)-principal. In particular, since \( K_{G_\kappa} \neq 0_{\mathfrak{R}} \), \( G_\kappa \) will not be \( \Sigma \)-cyclic.

We define a chain of \( \Sigma \)-cyclic groups \( \{ A_i \}_{i < \delta_m} \) satisfying the following:

1. For all \( n < \omega \), \( f_{A_i}(n) \), the \( n \)-th Ulm–Kaplansky invariant of \( A_i \), is \( |i| \cdot \aleph_0 \).
2. (0) If \( i < j \), then \( A_i \) is a pure subgroup of \( A_j \).
3. (1) If \( j \) is a limit, then \( \bigcup_{i < j} A_i = A_j \) (that is, the chain is smoothly ascending).
4. (3) If \( i < j \) and \( i \notin \mathcal{R}_m \), then \( A_i \) is a summand of \( A_j \).

Let \( A_0 = \{ 0 \} \). Suppose \( A_i \) has been defined for all \( i < j \); we then describe how to construct \( A_j \). If \( j \) is a limit, then (2) forces the definition of \( A_j \); note that (0), (1) and (4) follow easily. To verify that (3) continues to hold when \( i \notin \mathcal{R}_m \), suppose first that \( j \notin \mathcal{R}_m \). Since \( j < \delta_m \), it is not weakly Mahlo, so there is a CUB subset \( C \subseteq j \) such that \( C \cap \mathcal{R}_m = \emptyset \). Let \( \{ \alpha_l \}_{l < j} \) be an increasing enumeration of \( C \); there is clearly no loss of generality in assuming that \( \alpha_0 = i \). Since by induction on \( j \), for all \( l < j \), \( A_{\alpha_l} \) is a summand of \( A_{\alpha_{l+1}} \), it follows that

\[
A_j \cong A_i \oplus \left( \bigoplus_{l < j} A_{\alpha_{l+1}} / A_{\alpha_l} \right).
\]

On the other hand, if \( j \notin \mathcal{R}_m \), then let \( \lambda \) be the cofinality of \( j \). Define a closed and unbounded subset \( C' = \{ \beta_l \}_{l < \lambda} \subseteq j \) starting with \( \beta_0 = i \), \( \beta_1 > \lambda \), such that if \( l > 0 \) is isolated, then so is \( \beta_l \). We again claim that \( C' \cap \mathcal{R}_m = \emptyset \). Clearly, if \( l \) is isolated, then so is \( \beta_l \), so that \( \beta_l \notin \mathcal{R}_m \). And if \( l \) is a limit, then \( \text{cf}(\beta_l) \leq l < \lambda < \beta_l \).
so that again, $\beta_l \notin R_m$. It again follows that \( A_j \cong A_i \oplus \left( \bigoplus_{l < \lambda} A_{\beta_{l+1}} / A_{\beta_l} \right) \). (The last two paragraphs are usually summarized by saying \( R_m \) is a nonreflecting stationary subset of \( \kappa \).)

Suppose next that \( j = l + 1 \) is isolated. If \( l \notin R_m \), we merely let \( A_j = A_l \oplus \left( \bigoplus_{m < \omega} Z_p^m \right) \). Clearly, (0) and (1) hold, (2) and (4) say nothing new and (3) holds for \( j \) because it holds for \( l \).

Finally, suppose \( j = l + 1 \) and \( l \in R_m \). In this case, we let \( A_j \) be a \( \Sigma \)-cyclic group containing \( A_l \) as a pure subgroup such that \( A_j / A_l \cong G_l \); such a group can easily be constructed from a pure-projective resolution of \( G_l \). Clearly (4) holds for \( l \), (1) follows from the transitivity of purity and (2) does not involve any new conditions. Since \( G_l \) has cardinality \( l \) and for all \( n < \omega \) we have \( f_{A_j}(n) = f_{A_l}(n) + f_{G_l}(n) \), it follows that (0) holds for \( A_j \).

With regards to (3), assume \( i \notin R_m \) and \( i < j \); in particular, \( i < l \). Note that \( \{A_i\}_{i < l} \) is a filtration of \( A_l \). Similarly, there is a filtration \( \{S_i\}_{i < l} \) of \( A_j \) consisting of summands. By a standard “back-and-forth” argument, there is an ordinal \( i' \) such that \( i < i' < l \) and \( A_{i'} = S_{i'} \cap A_l \). Note that \( A_{i'} \) will be pure in \( A_j \) so that it is also pure in \( S_{i'} \). In addition, \( S_{i'}/A_{i'} \) has cardinality less than \( l \), and it maps injectively into \( A_j / A_l \cong G_l \). Since \( G_l \) is \( l \)-\( \Sigma \)-cyclic, it follows that \( S_{i'}/A_{i'} \) is also \( \Sigma \)-cyclic. Therefore, \( A_{i'} \) will be a summand of \( S_{i'} \). Since \( A_{i'} \) is a summand of \( A_{i'} \) by induction on (3) and \( S_{i'} \) is a summand of \( A_j \) by construction, \( A_i \) will be a summand of \( A_j \), as required.

Let \( G = \bigcup_{i < \delta_m} A_i \). We first claim that \( G \) is not \( \Sigma \)-cyclic. To verify this, recall that \( \{A_i\}_{i < \delta_m} \) is a filtration of \( G \) and \( R_m \) is a stationary subset of \( \delta_m \). For every \( i \in R_m \), the quotient \( G / A_i \) contains a subgroup, \( A_i+1/A_i \cong G_i \), which is not \( \Sigma \)-cyclic. It follows that \( G / A_i \) also fails to be \( \Sigma \)-cyclic. This means that \( G \) cannot be \( \Sigma \)-cyclic since that would imply that it has a filtration consisting of subgroups (that is, summands) such that these quotients are all \( \Sigma \)-cyclic.

We now need to verify that \( K_G = 0_R \). If this fails, then let \( T \) be a minimal subset of \( K_G \). Because \( G \) clearly has no nonzero element of infinite height, we can conclude that \( T \) is nonempty. Let \( \kappa = \mu(T) \); by the minimality of \( T \), (K2) and not (K1) must pertain. So there is a subgroup of \( A \) of \( G \) of cardinality \( \kappa \) such that \( \Gamma_{T'}(A) \) is stationary; it follows that \( \kappa \leq \delta_m \).

Suppose first that \( \kappa < \delta_m \). Since \( \{A_i\}_{i < \delta_m} \) is a filtration of \( G \) and \( \delta_m \) is regular, we can conclude that \( A \subseteq A_i \) for some \( i < \delta_m \). However, \( A_i \) is \( \Sigma \)-cyclic, so \( K_{A_i} = 0_R = \emptyset \). This contradicts the fact that \( T \in K_A \subseteq K_{A_i} \).

We may therefore assume that \( \kappa = \delta_m \). It follows that there is a stationary subset \( W \subseteq \delta_m \) such that \( T' \in K_{G/A_i} \) for all \( i \in W \) (see [Balof and Keef 2009, Lemma 2(b)], for example). Let \( \lambda = \mu(T') < \delta_m \), and let \( i \in W \) be chosen so that \( \lambda < i < \delta_m \). It follows that \( T' \in K_X \) for some subgroup \( X \subseteq G/A_i \) such that \( |X| = \lambda \). We will show, however, that this \( X \) must be \( \Sigma \)-cyclic so that \( K_X = \emptyset \).
Since $\delta_m$ is regular, we can conclude that $X \subseteq A_{i'}/A_i$ for some $i < i' < \delta_m$. Since $i + 1 \notin \mathcal{R}$, by (3) we have that $A_{i+1}$ is a summand of $A_{i'}$ so that

$$A_{i'}/A_i \cong (A_{i'}/A_{i+1}) \oplus (A_{i+1}/A_i).$$

Clearly, $X \subseteq X_1 \oplus X_2$, where $X_1 \subseteq A_{i'}/A_{i+1}$, $X_2 \subseteq A_{i+1}/A_i$ and $|X_1|, |X_2| \leq \lambda$. Since $A_{i'}/A_{i+1}$ is $\Sigma$-cyclic, it follows that $X_1$ is as well. In addition, $A_{i+1}/A_i$ is either $\Sigma$-cyclic (if $i \notin \mathcal{R}_m$) or $i$-$\Sigma$-cyclic (if $i \in \mathcal{R}_m$). Since $|X_2| \leq \lambda < i$, we can conclude that $X_2$ is also $\Sigma$-cyclic. This shows that $X$ must be $\Sigma$-cyclic and completes the argument. \hfill \Box

Again, the last result illustrates that in the presence of Mahlo cardinals, the invariant $K_G$ is insufficiently robust to answer question (N1) for arbitrarily large groups. To address this, we amend it significantly, concentrating on how it behaves at weakly Mahlo cardinals. We begin with some notation. If $T \in \mathcal{R}_f$ and $i < \mu(T)$ is an ordinal, let $T_i$ be $T_i = T' \cup \{i\}$ whenever $i$ is an uncountable regular cardinal, and otherwise, let $T_i = T'$, so $\mu(T_i) = (i \text{ or } \mu(T')) < \mu(T)$.

Given a group $G$, we define $L_G \subseteq \mathcal{R}_f$ not, as in the case of $K_G$, by traditional induction on $\nu(T)$ but rather by transfinite induction on $\mu(T)$. Suppose $T \in \mathcal{R}_f$ and we want to decide if $T \in L_G$. We begin with the same base case.

(L0) If $\mu(T) = \aleph_0$ (that is, $T = \emptyset$), we again let $T \in L_G$ if and only if $p^\omega G \neq \{0\}$.

Next, suppose for all groups $H$ we have defined all the elements $S \in L_H$ such that $\mu(S) < \kappa := \mu(T)$. In order to define when $T \in L_G$, we first observe that for any group $H$ we have defined when $T_i \in L_H$ for any $i < \kappa$. Replacing condition (K1), we say

(L1) $T \in L_G$ when

$$\Upsilon_T(G) := \{ i < \kappa : T_i \in L_G \}$$

is stationary in $\kappa$.

Replacing condition (K2), we also say

(L2) $T \in L_G$ when $G$ has a subgroup $A$ of cardinality $\kappa$ with a filtration $\mathcal{S} = \{ A_i \}_{i < \kappa}$ such that

$$\Lambda_T(A) := \{ i < \kappa : T_i \in L_{A/A_i} \}$$

is stationary in $\kappa$.

As in the definition of $K_G$, in this definition we are only concerned with whether $\Upsilon_T(G)$ and $\Lambda_T(A)$ are stationary in $\kappa$, and this property does not depend upon which particular filtration is chosen. Similarly, when we write something like $\Lambda_T(A) \subseteq \Lambda_T(G)$, we mean that $\Lambda_T(G) - \Lambda_T(A)$ is not stationary in $\kappa$, which again does not depend upon exactly which filtrations are used for $A$ and $G$. 
Since $T' \subseteq T_i$ for all $T \in \mathcal{R}_f$ and ordinals $i < \mu(T)$, an easy induction shows that $K_G \subseteq L_G$ for all groups $G$. On the other hand, suppose that $\kappa \in \mathcal{R}$ is not weakly Mahlo. It follows that there is a CUB subset $C \subseteq \kappa$ such that $C \cap \mathcal{R} = \emptyset$. If $\kappa = \mu(T)$, then for all $i \in C$ we have $T_i = T'$. This means that, away from weakly Mahlo cardinals, the two definitions agree. We state this more formally, as follows:

**Proposition 1.3.** If $G$ is a group, $T \in \mathcal{R}_f$ and $T \cap \mathcal{M} = \emptyset$, then $T \in L_G$ if and only if $T \in K_G$.

By [Balof and Keef 2009, Theorem 10], whose proof uses the above Lemma 1.1, and the last result, assuming the axiom of constructibility ($V = L$), if $\mathcal{A}$ is an $\mathcal{R}_f$-invariant whose minimal sets contain no weakly Mahlo cardinals, then there is a group $G$ such that $L_G = K_G = \mathcal{A}$. The proof of this uses stationary sets that are nonreflecting. In particular, such sets are plentiful in the constructible universe if one steers clear of weakly Mahlo cardinals (see [Eklof and Mekler 2002, Theorem VI, 3.13], for example). It is not clear what such a realization result would look like outside of $V = L$ and in the presence of weakly Mahlo cardinals.

It is consistent with ZFC that there are no weakly Mahlo cardinals (in fact, it is consistent that there are no regular limit cardinals at all). In any such model, Proposition 1.3 says that $K_G = L_G$ for all groups $G$. We pause for some straightforward observations that parallel facts about $K_G$ from [Balof and Keef 2009].

**Lemma 1.4.** Suppose $G$ and $H$ are groups and $S, T \in \mathcal{R}_f$.

(a) If $S \in L_G$ and $S \subseteq T$, then $T \in L_G$.

(b) $L_G = 1_\mathcal{R}$ if and only if $G$ has elements of infinite height.

(c) If $G$ is a subgroup of $H$, then $L_G \subseteq L_H$.

(d) If $G$ is a subgroup of $H$ and $|G| = |H| = \mu(T)$, then $\Upsilon_T(G) \subseteq \Upsilon_T(H)$.

(e) $L_G \oplus H = L_G \cup L_H$.

(f) If $T \in L_G$, then there is subgroup $A \subseteq G$ such that $|A| \leq \mu(T)$ and $T \in L_A$.

(g) If $T \in L_G$ is minimal under inclusion, then $\mu(T) \leq |G|$.

**Proof.** Consider (a); we prove this by induction on $\kappa := \mu(T)$.

If $\kappa = \aleph_0$, then $T = \emptyset$, and so therefore $T = S \in L_G$. Suppose now that $\kappa > \aleph_0$, $S \subseteq T$ and $S \in L_G$, so $T \neq \emptyset$. Suppose first that $\kappa \not\in S$. If $i < \kappa$, then $S \subseteq T_i$, so by induction, for all such $i$, we have $T_i \in L_G$. In particular, $\Upsilon_T(G)$ is stationary, and (L1) is satisfied.

Suppose next that $\kappa \in S$. It follows that for all $i < \kappa$, $S_i \subseteq T_i$. Therefore, by induction on $\kappa$, $\Upsilon_S(G) \subseteq \Upsilon_T(G)$. Also, if $A$ is a subgroup of $G$ of cardinality $\kappa$, then $\Upsilon_S(A) \subseteq \Upsilon_T(A)$. For $S$, one of these two sets must be stationary in $\kappa$, so the same must hold for $T$. 

Now (b) follows from (a) since \( L_G = 1_\mathbb{R} \) if and only if \( \emptyset \in L_G \) if and only if \( p^\alpha G \neq \{0\} \).

Turning to (c), we again show that if \( T \in L_G \), then \( T \in L_H \) by induction on \( \mu(T) \).

If \( \mu(T) = \aleph_0 \), then \( T = \emptyset \). This means \( G \) has elements of infinite height, so the same holds for \( H \), and \( T \in L_H \), as required. Suppose now that this holds for all sets \( S \in \mathcal{R}_f \) with \( \mu(S) < \kappa := \mu(T) \).

By induction on \( \kappa \), \( \mathcal{Y}_T(G) \subseteq \mathcal{Y}_T(H) \), so if (L1) holds for \( G \), it holds for \( H \). On the other hand, if \( A \) is a subgroup of \( G \) of cardinality \( \kappa \) such that \( \Lambda_T(A) \) is stationary in \( \kappa \), then \( A \) is equally a subgroup of \( H \), so again \( T \in L_H \).

Next, in (d), if \( \{B_i\}_{i<\kappa} \) is a filtration of \( H \), then letting \( A_i = G \cap B_i \) gives a filtration of \( G \). For all \( i < \kappa \), \( G/A_i \) embeds in \( H/B_i \), and the result follows from (c).

Turning to (e), the containment \( \supseteq \) follows from (c). We therefore need to show that every \( T \in L_G \cap H \) is in \( L_G \cup L_H \), which we again do by our usual induction on \( \kappa := \mu(T) \).

If \( \kappa = \aleph_0 \), then \( T = \emptyset \), and \( G \cup H \) has elements of infinite height. So either \( G \) or \( H \) has elements of infinite height; that is, \( T \in L_G \) or \( T \in L_H \).

Suppose now that this holds for all sets \( S \in \mathcal{R}_f \) with \( \mu(S) < \kappa := \mu(T) \).

By induction on \( \kappa \), \( \mathcal{Y}_T(G \cup H) = \mathcal{Y}_T(G) \cup \mathcal{Y}_T(H) \). Therefore, if (L1) holds for \( G \cup H \), one of the latter two sets is stationary, and appealing again to (L1) gives the result.

If (L2) pertains, then there is a subgroup \( C \subseteq G \cup H \) of cardinality \( \kappa \) such that \( \Lambda_T(C) \) is stationary in \( \kappa \). Note that \( C \) is contained in a subgroup of the form \( C' = A \cup B \) for some subgroups \( A \subseteq G \) and \( B \subseteq H \), where \( |C'| = \kappa \). By (d), \( \Lambda_T(C') \) will also be stationary. Replacing \( C \) by \( C' \), there is no loss of generality in assuming that \( C = A \cup B \).

If \( |A| = \kappa \), let \( \{A_i\}_{i<\kappa} \) be a filtration of \( A \), and otherwise, let each \( A_i = A \); define \( \{B_i\}_{i<\kappa} \) similarly. Clearly, \( \{A_i \cup B_i\}_{i<\kappa} \) is a filtration of \( C \). If \( |A| < \kappa \), then eventually \( C/C_i \cong B/B_i \) so that \( \Lambda_T(B) \) is stationary. This shows \( T \in L_H \), which completes the proof. Similarly reasoning applies if \( |B| < \kappa \), so assume \( |A| = |B| = \kappa \).

By induction on \( \kappa \), we can conclude that \( \Lambda_T(C) = \Lambda_T(A) \cup \Lambda_T(B) \). It follows that if (L2) holds for \( C \), then it holds for either \( A \) or \( B \), proving (e).

For (f), if \( \mu(T) = \aleph_0 \), then \( G \) has elements of infinite height. So \( G \) has a countable subgroup with elements of infinite height, which is what is being asserted.

Next, if \( W = \mathcal{Y}_T(G) \) is stationary in \( \kappa \), then by induction, for all \( i \in W \) there is a subgroup \( A_i \) of cardinality at most \( |i| \) such that \( T_i \in L_{A_i} \). We need only let \( A = (A_i : i \in W) \). On the other hand, if (L2) holds, then we need only let \( A \) be the subgroup mentioned there.

Finally, (g) is equivalent to the statement that if \( T \in L_G \) and \( |G| < \mu(T) \), then \( T \) is not minimal in \( L_G \). Observe first that if \( \mu(T) = \aleph_0 \), then \( G \) is finite. In particular, \( G \) has no elements of infinite height so that \( T \notin L_G \). Next, for the induction step, (L2) is clearly prohibited by \( |G| < \mu(T) \). Therefore, (L1) must hold. Choose some \( i \in \mathcal{Y}_T(G) \) such that \( |G| < i < \mu(T) \). By induction, there is a \( T_0 \subseteq T_i \) such
that \( T_0 \in L_G \) and \( \mu(T_0) \leq |G| \). But this second condition implies that \( T_0 \subseteq T' \subseteq T \), contradicting the minimality of \( T \).

Part (e) of Lemma 1.4 can be generalized to much larger direct sums. However, we will show later that it does not generalize to arbitrary direct sums, showing again that, in some respects at least, the invariant \( K_G \) is better behaved than the invariant \( L_G \).

The following minor variation on Fodor’s lemma (see [Jech 2003, Theorem 8.7], for example) will be crucial:

**Lemma 1.5.** Suppose \( \kappa \in \mathcal{R} \) and \( W \subseteq \kappa \) is a stationary subset. If \( f : W \to \mathcal{R} \) is a function such that \( f(i) \subseteq i \) for all \( i \in W \), then there is a stationary subset \( W' \subseteq W \) such that \( f(i) = f(j) \) for all \( i, j \in W' \).

**Proof.** If \( U_0 = \{ i \in W : f(i) = \emptyset \} \) is stationary in \( \kappa \), then we are clearly done. If not, let \( V_0 = W - U_0 \), so \( V_0 \) is also stationary. For every \( i \in V_0 \), let \( \phi_1(i) = \mu(f(i)) \in \mathcal{R} \). It follows that \( \phi_1 \) is a regressive function, so by Fodor’s lemma, there is an \( \alpha_1 \in \kappa \) and a stationary subset \( W_1 \subseteq V_0 \subseteq W \) such that \( \phi_1(i) = \alpha_1 \) for all \( i \in W_1 \).

We start the process over again. If \( U_1 = \{ i \in W : f(i) = \{ \alpha_1 \} \} \) is stationary in \( \kappa \), then we are clearly done. Otherwise, let \( V_1 = W_1 - U_1 \), so \( V_1 \) is also stationary. For every \( i \in V_1 \), let \( \phi_2(i) = \mu(f(i) - \{ \alpha_1 \}) \in \mathcal{R} \). It follows that \( \phi_2 \) is a regressive function, so by Fodor’s lemma, there is an \( \alpha_2 \in \kappa \) and a stationary subset \( W_2 \subseteq V_1 \subseteq W_1 \) such that \( \phi_2(i) = \alpha_2 \) for all \( i \in W_2 \). Clearly, \( \alpha_1 > \alpha_2 \).

Once again, if \( U_2 = \{ i \in W : f(i) = \{ \alpha_1, \alpha_2 \} \} \) is stationary in \( \kappa \), then we are clearly done. Continuing in this way, we keep constructing stationary subsets \( W \supseteq W_1 \supseteq W_2 \supseteq \cdots \supseteq W_k \) and ordinals \( \alpha_1 > \alpha_2 > \cdots > \alpha_k \). Since this sequence of ordinals cannot continue indefinitely, at some point we must have constructed the desired \( W' \). \( \square \)

Using an obvious extension of the usual terminology, we will call a function \( f \) as in Lemma 1.5 regressive. We have now arrived at one of our main results. Again, observe that it is valid for groups of arbitrarily large cardinality.

**Theorem 1.6.** A group \( G \) is \( \Sigma \)-cyclic if and only if \( L_G = 0_\mathcal{R} \).

**Proof.** Suppose first that \( G \) is \( \Sigma \)-cyclic. We again show by induction on \( \kappa := \mu(T) \) that \( T \not\in L_G \). If \( T = \emptyset \), then \( T \not\in L_G \) since \( G \) has no elements of infinite height. Suppose \( S \not\in L_G \) whenever \( \mu(S) < \mu(T) \). Since \( \mu(T_i) < \kappa \) for every \( i < \kappa \), by induction we can conclude \( \Upsilon_T(G) = \emptyset \) so that (L1) does not hold and \( T \not\in L_G \).

Next considering (L2), let \( A \) be any subgroup of \( G \) of cardinality \( \kappa \) and let \( \{ A_i \}_{i < \kappa} \) be a filtration of \( A \). Since \( A \) will also be \( \Sigma \)-cyclic, we may assume that each \( A_i \) is a summand of \( A \). It follows by induction that for all \( i < \kappa \), \( T_i \not\in L_{A/A_i} \); that is, \( \Lambda_T(A) = \emptyset \), and this implies that \( T \not\in L_G \), as required.

For the converse, we show by induction on \( \kappa := |G| \) that if \( L_G = 0_\mathcal{R} \), then \( G \) is \( \Sigma \)-cyclic. If \( \kappa = \aleph_0 \), then \( G \) will be a countable group without elements of infinite height.
height (since $\emptyset \notin L_G$). However, a countable group is $\Sigma$-cyclic if and only if it has no nonzero elements of infinite height, so the result holds in this case (see [Fuchs 1970, Theorem 17.3], for example). Next, assume the result holds for all groups of cardinality less than $\kappa > \aleph_0$ and that $L_G = 0_{3\mathfrak{r}}$. If $A$ is a subgroup of $G$ with $|A| < \kappa$, then by Lemma 1.4(c) we can conclude that $L_A = 0_{3\mathfrak{r}}$. By induction, then, $G$ is $\kappa$-$\Sigma$-cyclic.

Suppose first that $\kappa$ is singular. In this case, a variation of Shelah’s “Singular Compactness Theorem” (see [Keef 1990, Lemma 3.1], for example) implies that $G$ is $\Sigma$-cyclic, as required.

Suppose now that $\kappa$ is regular. Let $\{A_i\}_{i < \kappa}$ be a filtration of $G$ consisting of pure subgroups; there is clearly no loss of generality in assuming that $|A_i| = \aleph_0 \cdot |i|$ for all $i < \kappa$.

We claim that

$$C := \{ i < \kappa : G/A_i \text{ is } \kappa\text{-}\Sigma\text{-cyclic} \}$$

contains a CUB subset of $\kappa$. If we can establish this, and we enumerate this subset by $\{\beta_j\}_{j < \kappa}$, then it follows that

$$G \cong A_0 \oplus \left( \bigoplus_{j < \kappa} A_{\beta_{j+1}}/A_{\beta_j} \right),$$

and as all the terms in this decomposition are $\Sigma$-cyclic, the result follows.

Observe that if $C$ does not contain a CUB subset of $\kappa$, then

$$W := \kappa - C = \{ i < \kappa : G/A_i \text{ is not } \kappa\text{-}\Sigma\text{-cyclic} \}$$

must be stationary in $\kappa$. We assume this holds and derive a contradiction. There is clearly no loss of generality in assuming that every element of $W$ is infinite so that for all $i \in W$, $|A_i| = |i|$.

If $i \in W$, then since $G/A_i$ is not $\kappa$-$\Sigma$-cyclic, we can find a subgroup $X \subseteq G/A_i$ with $|X| < \kappa$ that is not $\Sigma$-cyclic. Let $Y$ be the subgroup of $G$ defined by the equation $Y/A_i = X$. Since $G$ is $\kappa$-$\Sigma$-cyclic and $|Y| < \kappa$, it follows that $Y$ is $\Sigma$-cyclic. Note that $A_i$ is contained in a summand $Z$ of $Y$ such that $|Z| = |A_i| = |i|$. This means that $X = Y/A_i \cong (Y/Z) \oplus (Z/A_i)$. Observe that $Y/Z$ is $\Sigma$-cyclic so that $Z/A_i$ fails to be $\Sigma$-cyclic. Since $|Z/A_i| \leq i < \kappa$, by induction, $L_{Z/A_i} \neq 0_{3\mathfrak{r}}$. Therefore, if $T^i$ is some minimal element in $L_{Z/A_i}$, then by Lemma 1.4(g), we have $\mu(T^i) \leq |i|$.

Define $f : W \to \mathfrak{R}_f$ by $f(i) = T^i - \{i\}$, so $f(i) = T^i$ unless $i$ is actually a regular cardinal that is the largest element of $T^i$, in which case $f(i) = (T^i)'$. By Lemma 1.5, there is a stationary subset $W' \subseteq W$ and $U \in \mathfrak{R}_f$ such that $f(i) = U$ for all $i \in W'$. The result then follows from the next statement, which contradicts the assumption that $L_G = 0_{3\mathfrak{r}}$. 
Claim. $V := U \cup \{ \kappa \} \in L_G$. Indeed, let $i \in W$. If $i \notin \mathcal{R}$, then $V_i = U = T_i \in L_{G/A_i}$. And if $i \in \mathcal{R}$, then $V_i = U \cup \{ i \} = T_i \cup \{ i \} \in L_{G/A_i}$. Therefore, $W' \subseteq \Lambda_V(G)$ so that $V \in L_G$, completing the proof. \hfill $\square$

The example constructed in the proof of Theorem 1.2 (assuming $V = L$ and the existence of Mahlo cardinals) has $K_G = 0_{\mathcal{R}}$, but since it is not $\Sigma$-cyclic, we have $L_G \neq 0_{\mathcal{R}}$. In particular, it is not the case that in all conceivable models of set theory, $K_G = L_G$ for all groups $G$.

2. The second question: Does $L_{G\upharpoonright H} = L_G \cdot L_H$?

In this section we investigate the question of whether $L_{G\upharpoonright H}$ always agrees with $L_G \cdot L_H$. One containment is straightforward.

**Theorem 2.1.** If $G$ and $H$ are groups, then $L_G \cdot L_H \subseteq L_{G\upharpoonright H}$.

**Proof.** As usual, if $T \in L_G \cdot L_H$, we show $T \in L_{G\upharpoonright H}$ by induction on $\kappa = \mu(T)$. Clearly, if $\kappa = \aleph_0$, then $T = \varnothing$; however, this implies that $\varnothing = \varnothing \cup \varnothing$ is in both $L_G$ and $L_H$. It then follows that both $G$ and $H$ have elements of infinite height. This, in turn, implies that $G \upharpoonright H$ also has elements of infinite height (see [Fuchs 1970, 62.4]) and $T = \varnothing \in L_{G\upharpoonright H}$. So assume the result holds for all groups $G$ and $H$ and all $S \in \mathcal{R}_f$ such that $\mu(S) \leq \kappa < \mu(T)$.

By definition, $T$ is the disjoint union of $U \in L_G$ and $V \in L_H$. Without loss of generality, assume $\kappa \in U$; let $\gamma = \mu(V) < \kappa$.

Consider the reason why $U \in L_G$. Since $\kappa \in U$, it is nonempty, so (L0) does not apply. Next, suppose (L1) holds so that $\Upsilon_U(G)$ is stationary in $\kappa$. Since whenever $\gamma < i < \kappa$, $T_i$ is the disjoint union $U_i \cup V$, it follows by transfinite induction that $\Upsilon_U(G) \cap (\kappa - \gamma) \subseteq \Upsilon_T(G \upharpoonright H)$.

This shows that $T \in L_{G\upharpoonright H}$, as required.

Now suppose that $B$ is a subgroup of $G$ of cardinality $\kappa$ such that $\Lambda_U(B)$ is stationary; let $\mathcal{B} = \{ B_i \}_{i < \kappa}$ be a pure filtration of $B$. By Lemma 1.4(f) there is a subgroup $C$ of $H$ such that $|C| \leq \gamma < \kappa$ and $V \in L_C$. Note that $\{ B_i \upharpoonright C \}_{i < \kappa}$ is a filtration of $B \upharpoonright C$ and for all $i < \kappa$ we have a pure exact sequence

$$0 \to B_i \upharpoonright C \to B \upharpoonright C \to (B/B_i) \upharpoonright C \to 0$$

(see [Fuchs 1970, 63.2], for example). By transfinite induction, for all $\gamma < i < \kappa$, if $i \in \Lambda_U(B)$, then $T_i = U_i \cup V \in L_{B/B_i} \cdot L_C$ implies $T_i \in L_{[(B/B_i)\upharpoonright C]} = L_{[(B\upharpoonright C)/(B_i \upharpoonright C)]}$. However, this means that $T \in L_{B \upharpoonright C} \subseteq L_{G \upharpoonright H}$, as required. \hfill $\square$

This brings us to our next major result.
Theorem 2.2. If $G$ and $H$ are groups, then $G \triangledown H$ is $\Sigma$-cyclic if and only if $L_{G \triangledown H} = 0_{\mathfrak{R}}$ if and only if $L_G \cdot L_H = 0_{\mathfrak{R}}$.

Proof. The first equivalence is an immediate consequence of Theorem 1.6. For the second, note first that if $G \triangledown H$ is $\Sigma$-cyclic, then $L_G \cdot L_H \subseteq L_{G \triangledown H} = 0_{\mathfrak{R}}$ by Theorem 2.1 so that $L_G \cdot L_H = 0_{\mathfrak{R}}$. For the converse, unlike the case of $K_G$, we do not actually show that $L_{G \triangledown H} \subseteq L_G \cdot L_H$ for all groups $G$ and $H$. We do, however, prove the following, which shows that if $L_G \cdot L_H$ is empty, then so is $L_{G \triangledown H}$:

Claim. If $T \in L_{G \triangledown H}$, then there is an $S \in L_G \cdot L_H$ such that $\mu(S) \leq \mu(T)$.

Once again, we prove this by a transfinite induction on $\mu(T) = \kappa$. Note first that if $\kappa = \aleph_0$, then $G \triangledown H$ has nonzero elements of infinite height. Therefore, both $G$ and $H$ also have such elements. We can then let $S = \emptyset = \emptyset \cup \emptyset \in L_G \cdot L_H$.

So assume the result holds for all groups $G$ and $H$ and all finite sets of regular cardinals $R$ with $\mu(R) < \kappa = \mu(T)$.

Suppose first that $\Upsilon_T(G \triangledown H)$ is stationary in $\kappa$. If $i$ is in this set, then $\mu(T_i) < \kappa$ so that by induction there is an $S \in L_G \cdot L_H$ such that $\mu(S) \leq \mu(T_i) < \kappa$.

Next, suppose there is a subgroup $A$ of $G \triangledown H$ of cardinality $\kappa$ such that $\Lambda_T(A)$ is stationary. After possibly expanding $A$ a bit, we may assume $A = B \triangledown C$, where $B$ and $C$ are subgroups of $G$ and $H$, respectively, and $\max(|B|, |C|) = \kappa$. We will be done if we can find an $S \in L_B \cdot L_C \subseteq L_G \cdot L_H$ with $\mu(S) \leq \kappa$.

Define $\{B_i\}_{i<\kappa}$ as follows: if $|B| < \kappa$, let each $B_i = B$; otherwise, let it be a filtration of $B$ consisting of pure subgroups. Define $\{C_i\}_{i<\kappa}$ in $C$ in an analogous fashion. It follows that $\{B_i \triangledown C_i\}_{i<\kappa}$ is a pure filtration of $B \triangledown C$. For each $i < \kappa$, the kernel of the obvious map

$$B \triangledown C \rightarrow [(B/B_i) \triangledown C] \oplus [B \triangledown (C/C_i)]$$

is

$$(B_i \triangledown C) \cap (B \triangledown C_i) = B_i \triangledown C_i$$

(see [Nunke 1967b, Lemma 7], for example) so that there is an embedding

$$(B \triangledown C)/(B_i \triangledown C_i) \rightarrow [(B/B_i) \triangledown C] \oplus [B \triangledown (C/C_i)].$$

Let $W = \Lambda_T(B \triangledown C)$, so $W$ is a stationary subset of $\kappa$. If $i \in W$, then $T_i$ is in $L_{(B \triangledown C)/(B_i \triangledown C_i)}$, and it follows from Lemma 1.4(c) that $T_i$ is either in $L_{(B/B_i) \triangledown C}$ or $L_{B \triangledown (C/C_i)}$. Without loss of generality, then, we may suppose that $T_i$ is in $L_{(B/B_i) \triangledown C}$ for all $i$ in a stationary subset $Y \subseteq W$; replacing $Y$ by $Y \cap (\mu(T'), \kappa)$, we may assume $\mu(T') < i$ for all $i \in Y$. For each $i \in Y$, by transfinite induction there are disjoint sets $U^i \in L_{B/B_i}$ and $V^i \in C$ such that $\mu(U^i \cup V^i) \leq \mu(T_i) \leq i$.

Observe that if $|B| < \kappa$, then $B/B_i = \{0\}$ for all $i \in Y$. But this would mean that $L_{B/B_i} = 0_{\mathfrak{R}}$, which contradicts that $U^i \in L_{B/B_i}$. We can conclude that $|B| = \kappa$ and that $\{B_i\}_{i<\kappa}$ actually is a filtration of $B$. 

Consider the function $Y \to R_f$ given by $f(i) = U^i \cap i = \{ x \in U^i : x < i \}$. Since $f$ is clearly regressive, by Lemma 1.5 there is a stationary subset $Z \subseteq Y$ such that for all $i \in Z$ we have $f(i) = P'$ for some fixed set $P' \in R_f$.

If we let $P = P' \cup \{ \kappa \}$, then $Z \subseteq \Lambda_P(B)$ so that $P \in L_B$. Choose any $i \in Z$, and set $Q := V^i \in L_C$; then $\kappa \not\in V_i$, $P \subseteq \{ \kappa \} \cup U^i$ and $U_i \cap V_i = \emptyset$ implies that $P \cap Q = \emptyset$. Therefore, $S := P \cup Q \in L_G \cdot LH$, and $\mu(S) = \kappa$, as required.

Let $\mathcal{M}_A$ be the class of weakly Mahlo cardinals that are accessible. So a weakly Mahlo cardinal is, in fact, Mahlo if and only if it is not in $\mathcal{M}_A$. Note that in the presence of the generalized continuum hypotheses, $\mathcal{M}_A$ is empty. Let $R' = R - \mathcal{M}_A$ and $R'_{f}$ be the class of finite subsets of $R'$. The following states that our product works fine as long as we stay clear of $\mathcal{M}_A$:

**Theorem 2.3.** If $G$ and $H$ are groups, then

$$L_{G \cdot \cap} \cap R'_{f} = L_G \cdot L_H \cap R'_{f}.$$  

**Proof.** Basically, we preserve the notation of the proof of Theorem 2.2 and show how to amend the argument to fit the present circumstances. By Theorem 2.1 we have the containment $\supseteq$; for the reverse, we perform our usual induction. If $\mu(T) = \aleph_0$, then $T = \emptyset$. So if $T \in L_{G \cdot \cap}$, then $G \cdot \cap$ has elements of infinite height, so the same is true of $G$ and $H$ so that $T \in L_G \cdot L_H$. Again, suppose the result holds for all $S \in R'_{f}$ such that $\mu(S) < \kappa := \mu(T)$ and $T \in L_{G \cdot \cap} \cap R'_{f}$.

Suppose first that (L1) holds so that $\gamma_T(G \cdot \cap) = \text{stationary in } \kappa$. If there is an $i \in \gamma_T(G \cdot \cap) - R$, then $T' = T_i \in L_{G \cdot \cap}$. By induction, $T' \in L_G \cdot L_H$, and this gives $T \in L_G \cdot L_H$, as required.

We may therefore assume that $\gamma_T(G \cdot \cap) \subseteq R$; in particular, this means that $\kappa$ is a weakly Mahlo cardinal. Since $T \cap \mathcal{M}_A = \emptyset$, $\kappa$ must actually be Mahlo, that is, strongly inaccessible. If we consider the function $f : \kappa \to \kappa$ given $f(\alpha) = 2^{[\alpha]}$, then there is a CUB subset $E \subseteq \kappa$ such that $E \cap \mu(T) = \emptyset$ and for all $\beta \in E$, if $\alpha < \beta$, then $2^{[\alpha]} < \beta$. Clearly any element of $E$ is strongly inaccessible. So any element of $E$ that is weakly Mahlo is actually Mahlo; that is, $E \cap \mathcal{M}_A = \emptyset$.

Note that $F := \gamma_T(G \cdot \cap) \cap E$ will also be stationary in $\kappa$. If $i \in F$, then $T_i \in R'_{f}$, so by transfinite induction, $T_i = U^i \cup V^i$, where $U^i \in L_G$ and $V^i \in L_H$ are disjoint. For every $i \in F$, either $i \in U^i$ or $i \in V^i$. Without loss of generality, assume $i \in U^i$ for a stationary subset $F' \subseteq F$. By Lemma 1.5, there is a stationary subset $F'' \subseteq F'$ such that $U' := U^i - \{ i \}$ and $V := V^i$ are constant for all $i \in F''$. Note that if we let $U = U' \cup \{ \kappa \}$, then $F'' \subseteq \gamma_U(G)$ so that $U \in L_G$. Since $V = V^i \in L_H$ and $T$ is the disjoint union of $U$ and $V$, we can conclude that $T \in L_G \cdot L_H$.

On the other hand, if (L2) holds, then there is a subgroup $A$ of $G \cdot \cap$ of cardinality $\kappa$ such that $W := \Lambda_T(A)$ is stationary. Again, we may assume $A = B \cdot \cap$, where $B$ and $C$ are subgroups of $G$ and $H$, respectively, and $\max(|B|, |C|) = \kappa$. 

We define \( \{B_i\}_{i<\kappa} \) and \( \{C_i\}_{i<\kappa} \) as before, so in particular, they are always pure subgroups of \( B \) and \( C \), respectively.

Continuing the argument as in Theorem 2.1 by using exact sequences for the torsion product, by transfinite induction we may assume there is a stationary subset \( Y \subseteq W \) such that \( Y \cap \mu(T') = \emptyset \) and for all \( i \in Y, T_i = U^i \cup V^i \) for disjoint subsets \( U^i \in L_{B/B_i} \) and \( V^i \in L_C \). And further, that \( |B| = \kappa \) and \( \{B_i\}_{i<\kappa} \) actually is a filtration of \( B \).

Appealing again to Lemma 1.5, we can find a stationary subset \( Z \subseteq Y \) such that for all \( i \in Z \), \( U^i \cap i \) always agrees with some fixed set \( P \) and \( V^i \cap i \) always agrees with some fixed set \( Q \). In particular, this means that \( T \) is the disjoint union \( P \cup Q \cup \{\kappa\} \).

We now divide the argument into two possibilities.

Case 1: \( Z_1 := \{i \in Z : V^i = Q\} \) is stationary in \( \kappa \).

If \( i \in Z_1 \), then since \( i \not\in V^i \), it follows that \( i \not\in U^i \) exactly when \( i \not\in B \). Therefore, if \( S := P \cup \{\kappa\} \) and \( i \in Z_1 \), it follows that \( S_i \) will coincide with \( U^i \in L_{B/B_i} \). This means \( Z_1 \subseteq \Lambda_S(B) \) so that \( S \subseteq L_B \subseteq L_G \). On the other hand, if \( i \in Z_1 \), then \( Q = V_i \in L_C \subseteq L_H \), and \( T \) is the disjoint union of \( Q \) and \( S \), completing this case.

This brings us to the more interesting possibility.

Case 2: \( Z_2 := \{i \in Z : V^i \neq Q\} \) is stationary in \( \kappa \).

Observe that if \( i \in Z_2 \), then \( i \in V^i \subseteq B \); that is, \( Z_2 \subseteq B \). This means that \( \kappa \) must be a (weakly Mahlo and hence) Mahlo cardinal. If \( R := Q \cup \{\kappa\} \), then \( R_i = Q \cup \{i\} = V^i \in L_H \) for all \( i \in Z_2 \), so it follows from (L1) that \( R \subseteq L_H \). Since \( T \) is the disjoint union \( R \cup P \), the result follows from the next statement.

Claim. \( P \subseteq L_G \).

Let \( \mu = \mu(P) < \kappa \). Again, \( \{B_i\}_{i<\kappa} \) is a pure filtration of \( B \), and we may clearly assume that \( |B_i| = |i| \cdot \aleph_0 \). For every \( i \in Z_2 \), \( i \not\in U^i \), so \( P = U^i \in L_{B/B_i} \). This means that \( B/B_i \) has a subgroup \( F_i \) of cardinality \( \mu \) such that \( P \subseteq L_{F_i} \). Now for each \( i \in Z_2 \), let \( D_i \) be a subgroup of \( B \) of cardinality \( \mu \) such that \( F_i = (B_i + D_i)/B_i \).

If \( i \in Z_2 \subseteq B \), then \( i \) is a regular cardinal, and since \( i \in Z \), we have \( P = i \cap U^i \) so that \( \mu < i \). Therefore, whenever \( i \in Z_2 \) there is an \( f(i) < i \) such that \( B_i \cap D_i \subseteq B_{f(i)} \).

By Fodor’s lemma, there is a stationary subset \( Z_3 \subseteq Z_2 \) such that \( f \) is constant on \( Z_3 \). Let \( \alpha = f(i) \) for all \( i \in Z_3 \). For \( i \in Z_3 \), let \( E_i = B_\alpha + D_i \). Clearly \( B_\alpha \) is a pure subgroup of \( E_i \) since it is a pure subgroup of \( B \). Note that

\[
E_i/B_\alpha = (B_\alpha + D_i)/B_\alpha \cong D_i/(B_\alpha \cap D_i) = D_i/(B_i \cap D_i) \cong (B_i + D_i)/B_i = F_i
\]

and so \( |E_i/B_\alpha| = |F_i| = \mu \).

Suppose \( M_1 \) is a divisible hull of \( B_\alpha \) and \( M_2 \) is a divisible group of rank \( \mu \), and set \( N := M_1 \oplus M_2 \). For every \( i \in Z_3 \), the inclusion \( B_\alpha \subseteq M_1 \) extends to an injective homomorphism \( \phi_i : E_i \to N \). Note that \( |N| = |B_\alpha| \cdot \mu < \kappa \), so \( N \) has only \( 2^{|N|} < \kappa \).
subsets (since $\kappa$ is strongly inaccessible). On the other hand, $|Z_3| = \kappa$. It follows that there are distinct $i, j \in Z_3$ such that $\phi_i(E_i) = \phi_j(E_j)$; assume $j < i$. Consider the homomorphism $\rho : E_i \to B$ given by $1_{E_i} - \phi_j^{-1} \circ \phi_i$. Since $\phi_i$ and $\phi_j$ are both the identity on $B_\alpha$, it follows that $B_\alpha$ is contained in the kernel of $\rho$.

But if $\pi : B \to B/B_i$ is the canonical epimorphism, then since $B_j \subseteq B_i$, we have $\pi \circ \rho = \pi - \pi \circ \phi_j^{-1} \circ \phi_i = \pi$. It follows that the kernel of $\rho$ is contained in the kernel of $\pi$, that is, $B_i$. However, $B_i \cap E_i = B_i \cap (B_\alpha + D_i) = B_\alpha + (B_i \cap D_i) = B_\alpha$ so that $B_\alpha$ must, in fact, be the kernel of $\rho$.

Therefore, $\rho$ induces an isomorphism between $E_i/B_\alpha \cong F_i$ and a subgroup $F$ of $B$. And since $i \in Z_3 \subseteq Z_2$, we know that $P \in L_{F_i} = L_F \subseteq L_G$. This established the claim and so completes the proof of the theorem. \hfill \qed

**Corollary 2.4.** Assuming the generalized continuum hypothesis, if $G$ and $H$ are any groups, then

$$L_{G \upharpoonright H} = L_G \cdot L_H.$$  

**Proof.** This follows directly from Theorem 2.3 since GCH implies that every regular limit cardinal is strongly inaccessible so that $M_A = \varnothing$. \hfill \qed

### 3. Applications and an independence result

The following is essentially [Keef 2008, Theorem 16] stated in terms of the invariants $K_G$ and $L_G$. It shows that, though in the presence of weakly Mahlo cardinals $K_G$ and $L_G$ may differ at times, they will always agree for torsion-complete groups.

**Proposition 3.1.** If $G$ is a torsion-complete group of final rank $\gamma$, then $K_G = L_G$ is generated by the $R_f$-antichain $\{ \{ \kappa \} : \kappa \in \mathcal{R}, \kappa \leq \gamma \}$. In other words, it is the $R_f$-invariant consisting of those $T \in R_f$ such that $T \cap \gamma^+ \neq \varnothing$.

**Proof.** Let $B$ denote a basic subgroup of $G$. Consider a decomposition $G \cong X \oplus G'$, where $X$ is bounded. Since $L_X = K_X = 0_{\mathcal{R}}$, we can replace $G$ by $G'$; that is, we may assume that $G$ has the same cardinality and final rank. Similarly, we may assume that $B$ has the same cardinality and final rank.

**Claim.** If $\kappa \in \mathcal{R}$ and $\kappa \leq \gamma$, then $\{ \kappa \} \in K_G$.

We split the argument into two cases. Suppose first that $|B| < \kappa$. It follows that $G/B \cong \bigoplus J \mathbb{Z}_{p^\infty}$, where $|J| = \gamma$. If $I \subseteq J$ with $|I| = \kappa$, then define $A$ by the equation $A/B \cong \bigoplus J \mathbb{Z}_{p^\infty}$. Let $\{ A_i \}_{i < \kappa}$ be a filtration of $A$; we may certainly assume that $A_0 = B$. It follows that $A/A_i$ will always be an epimorphic image of $A/B$, so $A/A_i$ will always be divisible. This shows that $\Gamma_{\varnothing}(A) = \kappa$, and in particular, it is stationary. This implies that $\{ \kappa \} \in K_G$.

Next, suppose $|B| \geq \kappa$. Let $B' = \bigoplus_{j < \kappa} C_j$ be a summand of $B$ such that each $C_j$ is a countable, unbounded $\Sigma$-cyclic group. Let $E$ be the set of all limit ordinals
in $\kappa$ of countable cofinality. If $i \in E$, let $X_i$ be a countable subgroup of $G$ such that there are proper containments

$$\bigcup_{l<i} \bigoplus C_j \subset X_i + \bigcup_{l<i} \bigoplus C_j \subset \bigoplus C_j$$

and such that $D_i = (X_i + \bigoplus_{j<i} C_j) / (\bigoplus_{j<i} C_j)$ is divisible. (In other words, $X_i$ is in the $p$-adic closure of $\bigoplus_{j<i} C_j$ but not in the $p$-adic closure of $\bigoplus_{j<i} C_j$ for any $l < i$; the existence of such a subgroup follows from the countable cofinality of $i \in E$.)

For all $i < \kappa$, let $E_i = \{ k \in E : k < i \}$ and $A_i = (\bigoplus_{j<i} C_j) + (\sum_{k \in E_i} X_k)$. Clearly, $\{ A_i \}_{i<\kappa}$ is a filtration of $A := \bigcup_{i<\kappa} A_i$ and $|A| = \kappa$. Now, if $i \in E$, then we assert that $A/A_i$ has elements of infinite height: to see this, note that $\bigoplus_{j<i} C_j \subseteq A_i$ and $X_i \subseteq A$, so there is a homomorphism $D_i \to A/A_i$, and since $X_i$ is not a subgroup of $A_i \subseteq \bigcup_{l<i} \bigoplus_{j<l} C_j$, the image of this map is nonzero, establishing the assertion.

We have shown that $E \subseteq \Gamma_\varnothing(A)$. Since $E$ is a stationary subset of $\kappa$, we can conclude that $\{ \kappa \} \in K_G$. This proves the claim.

Note that if $T \in \mathcal{R}_f$ is minimal in $L_G$, then by Lemma 1.4(g), we can conclude that $\mu(T) \leq \gamma$. So if we choose any $\kappa \in T$, then by our claim $\{ \kappa \} \in K_G \subseteq L_G$. The minimality of $T$ then implies that $T = \{ \kappa \}$. This means that $K_G$ and $L_G$ correspond to the same $\mathcal{R}_f$-antichain, namely this collection of singletons, and so they really are the same $\mathcal{R}_f$-invariant, namely this collection of singletons, and so they really are the same $\mathcal{R}_f$-invariant.

If $G$ is a group of final rank $\gamma$, then every minimal element of $K_G$ or $L_G$ must be contained in $\gamma^+$. Proposition 3.1 states that if $G$ is torsion-complete, then $L_G = K_G$ is the largest possible $\mathcal{R}_f$-invariant generated by nonempty subsets of $\gamma^+$.

We now consider a particularly simple case, that is, the torsion product of two unbounded torsion-complete groups with countable basic subgroups. We show that, though $K_G$ and $L_G$ agree on all torsion-complete groups, if we take torsion products, this may no longer be the case. Of course, $c = 2^{\aleph_0}$ denotes the continuum.

**Theorem 3.2.** Suppose $G$ is an unbounded torsion-complete group with a countable basic subgroup $B$. Then $K_{G\vee G}$ is generated by the $\mathcal{R}_f$-antichain consisting of all two-element subsets of $\mathcal{R} \cap c^+$, whereas $L_{G\vee G}$ is generated by the $\mathcal{R}_f$-antichain consisting of all two-element subsets of $(\mathcal{R} - \mathcal{M}) \cap c^+$, together with all one-element subsets of $\mathcal{M} \cap c^+$.

**Proof.** Because $K_{G\vee G} = K_G \cdot K_G$, the first statement follows directly from Proposition 3.1. Next, note that if $T$ is any two-element subset of $\mathcal{R} - \mathcal{M}$ with $\mu(T) \leq c$, then by Proposition 1.3, $T \in K_{G\vee G}$ will also be minimal in $L_{G\vee G}$. Finally, we need to show that the following holds:

**Claim.** If $\delta \leq c$ is weakly Mahlo, then $\{ \delta \} \in L_{G\vee G}$.
Let $A$ be a pure subgroup of $G$ containing $B$ with $|A| = \delta$, and let $\{A_i\}_{i<\delta}$ be a pure filtration of $A$ starting with $A_0 = B$. We may clearly assume that for all $0 < i < \delta$ we have $|A_i| = |i| \cdot \aleph_0$. Therefore, if $i \in \mathcal{R} \cap \delta$, then $\{A_j\}_{j<i}$ will be a pure filtration of $A_i$, and $A_i/A_j$ will always be divisible. This implies that $\Lambda_{|i|}(A_i) = i$ so that $\{i\} \subseteq L_{A_i}$ whenever $i \in \mathcal{R} \cap \delta$.

Now $\{A_i \cap A_i\}_{i<\delta}$ will be a filtration of $A \triangle A$. If $i \in \mathcal{R} \cap \delta$, then

$$\frac{(A_i \cap A_i)}{(A_i \cap A_i)} \subseteq \frac{(A \cap A)}{(A_i \cap A_i)}.$$ 

The pure exact sequence $0 \to A_i \to A \to A/A_i \to 0$ leads to a pure exact sequence

$$0 \to A_i \cap A_i \to A_i \cap A \to A_i \cap (A/A_i) \to 0.$$ 

Since $A/A_i$ is divisible, it is isomorphic to a direct sum of $\delta$ copies of $\mathbb{Z}_{p^\infty}$. So

$$\frac{(A_i \cap A)}{(A_i \cap A_i)} \cong A_i \cap (A/A_i)$$

will be isomorphic to a direct sum of copies of $A_i$. In particular, this shows that $\frac{(A \cap A)}{(A_i \cap A_i)}$ has a subgroup isomorphic to $A_i$. So if $i \in \mathcal{R} \cap \delta$, then $\{i\} \subseteq L_{A_i} \subseteq L_{(A \cap A)/(A_i \cap A_i)}$.

The above computation shows that

$$\mathcal{R} \cap \delta \subseteq \Lambda_{|\delta|}(A \cap A).$$

But by (L2), this implies that $\{\delta\} \subseteq L_{G \cap G}$, as required. □

Theorem 3.2 makes it clear why the continuum hypothesis (CH) is equivalent to $G \cap G$ being $\Sigma$-cyclic. (This was [Keef 1991, Proposition 5] though the result was known before that paper.) If CH holds, then $(\mathcal{R} - \mathcal{M}) \cap c^+ = \{\aleph_1\}$ has no two-element subsets, and $\mathcal{M} \cap c^+ = \emptyset$ has no one-element subsets; this means that $L_{G \cap G}$ is empty. And on the other hand, if CH fails, then $\{\aleph_1, \aleph_2\}$ will be a two-element subset of $(\mathcal{R} - \mathcal{M}) \cap c^+$, so $L_{G \cap G}$ is nonempty. The next result is a striking parallel with regards to $L_G$, $c$ and $\delta_m$.

Corollary 3.3. If $G$ is an unbounded torsion-complete group with a countable basic subgroup, then $L_{G \cap G} = L_G \cdot L_G$ if and only if $c = 2^{\aleph_0} < \delta_m$.

Proof. If $c < \delta_m$, then $(\mathcal{R} - \mathcal{M}) \cap c^+ = \mathcal{R} \cap c^+$ and $\mathcal{M} \cap c^+ = \emptyset$. It follows then from Proposition 3.1 and Theorem 3.2 that $L_{G \cap G} = K_{G \cap G} = K_G \cdot K_G = L_G \cdot L_G$.

Conversely, if $\delta_m \leq c$, then by Theorem 3.2, $\{\delta_m\} \subseteq L_{G \cap G}$. However, since every set in $L_G \cdot L_G$ has at least two-elements, $\{\delta_m\} \not\subseteq L_G \cdot L_G$. □

It is tempting to think that in any model of ZFC we must have $c < \delta_m$. After all, a Mahlo cardinal, even a weakly Mahlo cardinal, ought to be extremely large; certainly much larger than the continuum. The following, however, shows that this need not be the case. (I am thankful to Prof. Joan Bagaria for this argument.)
**Theorem 3.4.** If there is a model of ZFC that contains a weakly Mahlo cardinal, then there is a model of ZFC in which there is a weakly Mahlo cardinal smaller than the continuum.

*Proof.* Start with a model $V$ of ZFC in which there is a weakly Mahlo cardinal $\delta$. Let $\gamma$ be any regular cardinal greater than $\delta$. The usual way to construct a model of ZFC with at least $\gamma$ Cohen reals is to define the notion of forcing $P$ to be the set of all functions from a finite subset of $\gamma \times \omega$ to $\{0, 1\}$ (see [Jech 2003, 15.1], for example). If $p, q \in P$, then let $p \leq q$ (that is, $p$ is stronger than $q$) if and only if $p \supseteq q$. By [Jech 2003, Lemma 14.25], this $P$ satisfies the c.c.c. (countable chain condition). Therefore, if we use $P$ to construct a generic extension $V[G]$ of $V$, then in $V[G]$ we will have $\delta < \gamma \leq c$ since $G \in V[G]$ can be thought of as a collection of $\gamma$ distinct functions $\omega \to \{0, 1\}$. (In fact, $c^{V[G]} = (2^\kappa)^{V[G]} = (\gamma^{\aleph_0})^V$, but we do not need to be precise.)

By [Jech 2003, Theorem 14.34], $V$ and $V[G]$ have the same cardinals and cofinalities. This implies that the class $\mathcal{R}$ does not change when we go from $V$ to $V[G]$. And in particular, this means that $\delta$ remains a regular cardinal.

Next, note that for all $\kappa \in \mathcal{R}$, since $P$ is c.c.c., it is $\kappa$-c.c. (every antichain in $P$ has cardinality less than $\kappa$). It follows from [Jech 2003, Lemma 22.25] that if $S \in V$ is a stationary subset of $\kappa$ in $V$, then $S$ remains stationary in $V[G]$. In particular, this means that $\mathcal{R} \cap \delta$ will remain stationary in $\delta$ so that $\delta$ remains weakly Mahlo in $V[G]$. \qed

**Corollary 3.5.** If ZFC is consistent, then there exists a model of ZFC in which $L_{G \oplus H} = L_G \cdot L_H$ holds for all groups $G$ and $H$. On the other hand, if there is a model of ZFC in which there is a weakly Mahlo cardinal, then there is a model of ZFC in which $L_{G \oplus H} \neq L_G \cdot L_H$ for some pair of groups $G$ and $H$.

*Proof.* For the first statement, just take any model in which GCH holds (e.g., a model of $V = L$). For the second, consider a model in which $\delta_m < c$, and let $G = H$ be an unbounded torsion-complete group with a countable basic subgroup. \qed

We have seen that the $\mathcal{R}_f$-invariants $K_G$ have some advantages over the corresponding $\mathcal{R}_f$-invariants $L_G$. That is, for all groups $G$ and $H$, we know that $K_{G \oplus H} = K_G \cdot K_H$, but this equation is much more complicated for $L_G$. In addition, if $\{G_i\}_{i \in I}$ is a collection of groups, by [Balof and Keef 2009, Theorem 3(a)] we have $K_{\bigoplus_{i \in I} G_i} = \bigcup_{i \in I} K_{G_i}$. On the other hand, we have the following result:

**Theorem 3.6.** A weakly Mahlo cardinal exists if and only if there is a collection of groups $\{G_i\}_{i \in I}$ such that $L_{\bigoplus_{i \in I} G_i} \neq \bigcup_{i \in I} L_{G_i}$. 

Proof. If no weakly Mahlo cardinal exists, then $\delta_m = \infty$, and for all groups $G$ we have $L_G = K_G$. So the result follows from [Balof and Keef 2009, Theorem 3(a)].

On the other hand, if $\delta_m < \infty$, then let $I = \mathcal{R} \cap \delta_m$, and let $H$ be a torsion-complete group of final rank at least $\delta_m$. According to Proposition 3.1 and Lemma 1.4(f), if $i \in I$, then $H$ has a subgroup $G_i$ of cardinality $i$ such that $\{i\} \in L_{G_i}$. We let $G$ be the external direct sum $\bigoplus_{i \in I} G_i$. If for all $j < \delta_m$ we let $A_j = \bigoplus_{i < j} G_i$, then $\{A_j\}_{j < \delta_m}$ is a filtration of $G$. Since for all $j \in I$, $G_j$ embeds in $G/A_j$, it follows that $\Lambda_{G} G \supseteq I$ is stationary. By (L2), this implies that $\{\delta_m\} \in L_G$. However, if $\{\delta_m\}$ was an element of some $L_G$, since $|G_i| = i < \delta_m$ we could conclude from Lemma 1.4(f) that $\{\delta_m\}$ is not minimal. This, in turn, would imply that $\emptyset \in L_{G_i}$ so that $G_i$ has nonzero elements of infinite height. Therefore, $\{\delta_m\} \notin \bigcup_{i \in I} L_{G_i}$, so the two sets disagree. 

We will need the following extension of Theorem 2.2:

**Corollary 3.7.** If $G_1, \ldots, G_n$ are groups, then $G_1 \triangledown \cdots \triangledown G_n$ is $\Sigma$-cyclic if and only if $L_{G_1} \cdots L_{G_n} = 0_{\mathcal{R}}$.

It would be tempting to say that Corollary 3.7 follows directly from Theorem 2.2 by simply inducting on $n$. This does not quite work, however. For example, if $n = 3$, then $G_1 \triangledown G_2 \triangledown G_3$ will be $\Sigma$-cyclic if and only if $L_{G_1} \triangledown G_2 \cdot L_{G_3} = 0_{\mathcal{R}}$, but at this stage we are stuck since we do not necessarily have $L_{G_1} \triangledown G_2 = L_{G_1} \cdot L_{G_2}$.

The way to verify Corollary 3.7 is to go back to the proof of Theorem 2.2. That proof was done with only two terms, but essentially the same argument can be made with any finite number of terms. The notation is much more cumbersome, but the ideas are identical, and so we omit them. This brings us to our final result, an extension of [Balof and Keef 2009, Theorem 55]. Since that proof was embedded in a much more involved discussion of the structure of $\mathcal{R}_f$-invariants, we provide this self-contained argument. Observe that it is a complete characterization of the groups that positively answer Nunke’s question.

**Theorem 3.8.** If $G$ is a group (of arbitrary cardinality), then the following are equivalent:

(a) There is a group $H$ that is not $\Sigma$-cyclic such that $G \triangledown H$ is $\Sigma$-cyclic.

(b) There is no infinite pairwise disjoint subset of $L_G$.

(c) For some positive integer $n$, $G^n = G \triangledown G \triangledown \cdots \triangledown G$ is $\Sigma$-cyclic.

**Proof.** Suppose (a) holds so that $L_H \neq 0_{\mathcal{R}}$ and $L_G \cdot L_H = 0_{\mathcal{R}}$. Let $S \in L_H$, and suppose $S = \{\alpha_1, \alpha_2, \ldots, \alpha_m\}$. We assume $\{T_k\}_{k<\omega}$ is an infinite pairwise disjoint collection from $L_G$ and derive a contradiction. Note that each $T_k$ must intersect $S$ nontrivially since $L_G \cdot L_H = 0_{\mathcal{R}}$. On the other hand, since the $T_k$s are disjoint, every element of $S$ can be in at most one of them. So the fact that there are only a finite number of elements of $S$ contradicts the fact that there are an infinite number of $T_k$s.
We suppose now that (b) holds and verify (c); actually, we will assume that (c) fails, and verify that (b) must also fail. To that end, suppose we have constructed a pairwise disjoint collection in $L_G$ and $T_1, \ldots, T_k$; we will verify that there must be a $T_{k+1} \in L_G$ that is disjoint from them all. Let $n$ be one more that the total number of elements in $T_1 \cup \cdots \cup T_k$. Since by Corollary 3.7, $(L_G)^n \neq 0_{\beta \beta}$, there is a pairwise disjoint collection $S_1, \ldots, S_n$ in $L_G$. Since the $S_j$s are disjoint, no element of $T_1 \cup \cdots \cup T_k$ is in more than one $S_j$. Therefore, there must be an $S_j$ disjoint from all the $T_i$s, and we just let $T_{k+1}$ be this $S_j$.

We suppose now that (c) holds and verify (a). If $G$ is $\Sigma$-cyclic, then we can let $H$ be any group that is not $\Sigma$-cyclic. Otherwise, choose $n$ to be the least positive integer such that $G^n$ is $\Sigma$-cyclic. So $n > 1$ (since $G$ is not $\Sigma$-cyclic) and $H := G^{n-1}$ is not $\Sigma$-cyclic, but $G \vartriangledown H = G^n$.

The following shows that torsion-complete groups can be used as “test groups” for the $\Sigma$-cyclic groups:

**Corollary 3.9.** Suppose $G$ is a torsion-complete group of final rank at least $\aleph_\omega$. If $H$ is any group, then $H$ is $\Sigma$-cyclic if and only if $G \vartriangledown H$ is $\Sigma$-cyclic.

**Proof.** By Proposition 3.1, for every $m < \omega$, $\{\aleph_m\} \in L_G$, so $G$ satisfies the denial of Theorem 3.8(b), and the result follows from the denial of Theorem 3.8(a). □

In summary, the new invariant $L_G$ “solves” Nunke’s problem in the sense that it reduces it from a question involving the torsion product to a question of being able to compute $L_G$. As we have seen, however, even for a standard torsion-complete group, calculating $L_G$ involves significant questions of cardinal arithmetic.

Nunke’s problem can be generalized to asking when $G \vartriangledown H$ is a direct sum of countable groups (which we abbreviate to d.s.c. group) of length $\lambda \leq \omega_1$. If $\lambda = \omega_1$, we showed in [Keef 1989] that the answer to this question depends upon a set-theoretic statement known as Kurepa’s Hypothesis (see [Jech 2003, Definition 9.24]). On the other hand, for all countable $\lambda < \omega_1$ the above techniques can be generalized to answer the question of when $G \vartriangledown H$ is a d.s.c. group of length $\lambda$.

Define an invariant $L^\lambda_G$ inductively as follows:

- **(L^\lambda 0)** If $\mu(T) = \aleph_0$ (that is, $T = \emptyset$), $T \in L^\lambda_G$ if and only if $p^\lambda G \neq \{0\}$.

Next, suppose for all groups $H$ we have defined all the elements $S \in L^\lambda_H$ such that $\mu(S) < \kappa := \mu(T)$. We then say $T \in L^\lambda_G$ if and only if one of two things occurs:

- **(L^\lambda 1)** $\Upsilon^\lambda_T(G) := \{ i < \kappa : T_i \in L^\lambda_G \}$ is stationary in $\kappa$, or
- **(L^\lambda 2)** $G$ has a subgroup $A$ of cardinality $\kappa$ with a filtration $\{A_i\}_{i < \kappa}$ such that $\Lambda^\lambda_T(A) := \{ i < \kappa : T_i \in L^\lambda_{A/A_i} \}$ is stationary in $\kappa$. 

So all that really has to be changed is the base case, \((L^\lambda_0)\) versus \((L_0)\).

Next, recall from [Keef 1991] that the group \(G\) is a \(C_\lambda\)-group if for every \(\alpha < \lambda\), \(G\) has an \(\alpha\)-high subgroup that is a d.s.c. group. In particular, a d.s.c. group will always be a \(C_\lambda\) group, and every group is a \(C_\omega\)-group. The following can be proven in an essentially identical manner to the results of this paper:

**Theorem 3.10.** If \(G\) and \(H\) are groups and \(\lambda < \omega_1\) is a countable ordinal, then \(G \vartriangleleft H\) is a d.s.c. group of length \(\lambda\) if and only if \(G\) and \(H\) are \(C_\lambda\) groups of length at least \(\lambda\) and \(L^\lambda_G \cdot L^\lambda_H = 0\).

Similarly, virtually all of the results of this paper can be recast to statements involving d.s.c. groups of countable length.

There are difficulties in translating these results to groups of uncountable length and, in particular, to simply presented groups of arbitrary length. The base case in the definition \(L^\lambda_G\) really depends upon the countability of \(\lambda\). In particular, if \(\varnothing \in L^\lambda_G\), we would like to conclude that there is a countable subgroup \(A \subseteq G\) such that \(\varnothing \in L^\lambda_A\) (cf., Lemma 1.4(f)), but this is not true if \(\lambda \geq \omega_1\). Correspondingly, as was shown in [Hill 1983a], if \(G\) and \(H\) are reduced groups, then \(G \vartriangleleft H\) will never be a simply presented group of uncountable length. Some of these issues will be discussed in later work.

**Acknowledgements**

This research was completed while I was a visiting scholar at the Institut de Matemàtica, Universitat de Barcelona. I am grateful to the Institut, and to its director, Carles Casacuberta, for their hospitality during my stay.

The argument in the proof of Theorem 3.4 was provided by Professor Joan Bagaria of the Universitat de Barcelona. I am very grateful to him for his assistance in clarifying this part of my investigations.
