GROSSBERG–KARSHON TWISTED CUBES AND HESITANT WALK AVOIDANCE

Megumi Harada and Eunjeong Lee
Let $G$ be a complex semisimple simply connected linear algebraic group. Let $\lambda$ be a dominant weight for $G$ and $\mathcal{I} = (i_1, i_2, \ldots, i_n)$ a word decomposition for an element $w = s_{i_1}s_{i_2}\cdots s_{i_n}$ of the Weyl group of $G$, where the $s_i$ are the simple reflections. In the 1990s, Grossberg and Karshon introduced a virtual lattice polytope associated to $\lambda$ and $\mathcal{I}$, which they called a twisted cube, whose lattice points encode (counted with sign according to a density function) characters of representations of $G$. In recent work, Harada and Jihyeon Yang proved that the Grossberg–Karshon twisted cube is untwisted (so the support of the density function is a closed convex polytope) precisely when a certain torus-invariant divisor on a toric variety, constructed from the data of $\lambda$ and $\mathcal{I}$, is basepoint-free. This corresponds to the situation in which the Grossberg–Karshon character formula is a true combinatorial formula, in the sense that there are no terms appearing with a minus sign. In this note, we translate this toric-geometric condition to the combinatorics of $\mathcal{I}$ and $\lambda$. More precisely, we introduce the notion of hesitant $\lambda$-walks and then prove that the associated Grossberg–Karshon twisted cube is untwisted precisely when $\mathcal{I}$ is hesitant-$\lambda$-walk-avoiding. Our combinatorial condition imposes strong geometric conditions on the Bott–Samelson variety associated to $\mathcal{I}$.
Introduction

Let $G$ be a complex semisimple simply connected linear algebraic group. Building combinatorial models for $G$-representations is a fruitful technique in modern representation theory; a famous example is the theory of crystal bases and string polytopes. In a different direction, given a dominant weight $\lambda$ and a choice of word expression $\mathcal{J} = (i_1, i_2, \ldots, i_n)$ of an element $w = s_{i_1}s_{i_2} \cdots s_{i_n}$ in the Weyl group, Grossberg and Karshon [1994] introduced a combinatorial object called a twisted cube $(C(c, \ell), \rho)$, where $C(c, \ell)$ is a subset of $\mathbb{R}^n$ and $\rho$ is a support function with support precisely $C(c, \ell)$. The lattice points of $C(c, \ell)$ encode (counted with $\pm$ sign according to $\rho$) the character of the $G$-representation $V_\lambda$ [Grossberg and Karshon 1994, Theorems 5 and 6]. Here the parameters $c$ and $\ell$ are determined from $\lambda$ and $\mathcal{J}$. These twisted cubes are combinatorially much simpler than general string polytopes but they are not true polytopes in the sense that their faces may have various angles and the intersection of faces may not be a face (cf. [Grossberg and Karshon 1994, §2.5 and Figure 1 therein]), and in general they may be neither closed nor convex (see Example 1.2). In particular, the Grossberg–Karshon character formula is not a purely combinatorial positive formula, since it may involve minus signs.

The main result of this note gives necessary and sufficient conditions on a dominant weight $\lambda$ and a (not necessarily reduced) word expression $\mathcal{J} = (i_1, \ldots, i_n)$ of an element $w \in W$ such that the associated Grossberg–Karshon twisted cube is untwisted (cf. Definition 1.3), i.e., $C(c, \ell)$ is a closed convex polytope and $\rho$ is identically equal to 1 on $C(c, \ell)$. This is precisely the situation in which the Grossberg–Karshon character formula is a true combinatorial formula, in the sense that it is a purely positive formula (with no terms appearing with a minus sign). In addition, an anonymous referee pointed out to us that the combinatorial condition on $\mathcal{J}$ and $\lambda$ in our result also has interesting geometric consequences: it implies that (the image in a flag variety of) the corresponding Bott–Samelson variety is a toric Schubert variety in the sense of [Karuppuchamy 2013]; see Remark 2.10.

In order to state our result it is useful to introduce some terminology (see Section 2 for details). Roughly, we say that a word $\mathcal{J} = (i_1, \ldots, i_n)$ is a diagram walk (or simply walk) if successive roots are adjacent in the Dynkin diagram: for instance, in type $A_5$

```
1 -- 2 -- 3 -- 4 -- 5
```

the word $\mathcal{J} = (2, 4, 5)$ with corresponding simple roots $(s_2, s_4, s_5)$ is not a walk since $s_2$ and $s_4$ are not adjacent, but $\mathcal{J} = (1, 2, 3, 2, 1)$ is a walk. Moreover, given a dominant weight $\lambda = \lambda_1 \varpi_1 + \cdots + \lambda_r \varpi_r$ written as a linear combination of the fundamental weights $\{\varpi_1, \ldots, \varpi_r\}$, we say $\mathcal{J} = (i_1, i_2, \ldots, i_n)$ is a $\lambda$-walk if it is a walk and if it ends at a root which appears in $\lambda$, i.e., $\lambda_{i_n} > 0$. A hesitant $\lambda$-walk is a word $\mathcal{J} = (i_0, i_1, \ldots, i_n)$ where $i_0 = i_1$, so there is a repetition at the first step, and
the subword \((i_1, i_2, \ldots, i_n)\) is a \(\lambda\)-walk. Finally, a word is \textit{hesitant-}\(\lambda\)-\textit{walk-avoiding} if there is no subword which is a hesitant \(\lambda\)-walk. With this terminology we can state the main result of this paper.

**Theorem.** Let \(\mathcal{J} = (i_1, i_2, \ldots, i_n)\) be a word decomposition of an element \(w = s_{i_1}s_{i_2}\cdots s_{i_n}\) of the Weyl group \(W\) and let \(\lambda = \lambda_1 \varpi_1 + \lambda_2 \varpi_2 + \cdots + \lambda_r \varpi_r\) be a dominant weight. Then the corresponding Grossberg–Karshon twisted cube \((C(c, \ell), \rho)\) is untwisted if and only if \(\mathcal{J}\) is hesitant-\(\lambda\)-walk-avoiding.

We note that pattern avoidance is an important notion in the study of Schubert varieties and Schubert calculus, first pioneered by Lakshmibai and Sandhya [1990] and further studied by many others (see, e.g., [Abe and Billey 2014] and references therein). It would be interesting to explore the relation between our notion of hesitant-\(\lambda\)-walk-avoidance with the other types of pattern avoidance in the theory of flag and Schubert varieties.

We additionally remark that Kiritchenko has recently defined \textit{divided-difference operators} \(D_i\) on polytopes and, using these \(D_i\) inductively together with a fixed choice of reduced word decomposition for the longest element in the Weyl group of \(G\), she constructs (possibly virtual) polytopes whose lattice points encode the character of irreducible \(G\)-representations [Kiritchenko 2013, Theorem 3.6]. Kiritchenko’s virtual polytopes are generalizations of both Gel’fand–Cetlin polytopes and the Grossberg–Karshon twisted polytopes. It would be interesting to explore whether our methods can be further generalized to study Kiritchenko’s virtual polytopes (see Section 5).

This paper is organized as follows. In Section 1 we recall the necessary definitions and background from previous papers. In particular, we recall the results of Harada and Yang [2015, Proposition 2.1 and Theorem 2.4] which characterize the untwistedness of the Grossberg–Karshon twisted cube in terms of the Cartier data associated to a certain toric divisor on a toric variety; this is a key tool for our proof. In Section 2 we introduce the notions of diagram walks and hesitant \(\lambda\)-walks and state our main theorem. We prove the sufficiency of hesitant-\(\lambda\)-walk-avoidance in Section 3. The proof of necessity, which occupies Section 4, is in part a case-by-case analysis according to Lie type. We briefly record some open questions in Section 5.

1. **Background**

We begin by recalling the definition of \textit{twisted cube} given by Grossberg and Karshon [1994, §2.5]. We follow the exposition in [Harada and Yang 2015]. Fix a positive integer \(n\). A twisted cube is a pair \((C(c, \ell), \rho)\) where \(C(c, \ell)\) is a subset of \(\mathbb{R}^n\) and \(\rho : \mathbb{R}^n \to \mathbb{R}\) is a density function with support precisely equal to \(C(c, \ell)\). Here \(c = \{c_{jk}\}_{1 \leq j < k \leq n}\) and \(\ell = \{\ell_1, \ell_2, \ldots, \ell_n\}\) are fixed integers. (The general definition in [Grossberg and Karshon 1994] only requires the \(\ell_i\) to be real numbers, but since
we restrict our attention to the cases arising from representation theory, our \( \ell_i \) will always be integers.) In order to simplify the notation in what follows, we define the following functions on \( \mathbb{R}^n \):

\[
\begin{align*}
A_n(x) &= A_n(x_1, \ldots, x_n) = \ell_n, \\
A_j(x) &= A_j(x_1, \ldots, x_n) = \ell_j - \sum_{k > j} c_{jk} x_k \quad \text{for all } 1 \leq j \leq n - 1.
\end{align*}
\]

We also define a function \( \text{sgn} : \mathbb{R} \to \{ \pm 1 \} \) by \( \text{sgn}(x) = 1 \) for \( x < 0 \) and \( \text{sgn}(x) = -1 \) for \( x \geq 0 \).

We now give the precise definition.

**Definition 1.1.** Let \( n, c, \ell, \) and \( A_j \) be as above. Let \( C(c, \ell) \) denote the following subset of \( \mathbb{R}^n \):

\[
C(c, \ell) := \{ x = (x_1, \ldots, x_n) \in \mathbb{R}^n \mid \forall 1 \leq j \leq n, A_j(x) < x_j < 0 \text{ or } 0 \leq x_j \leq A_j(x) \}.
\]

Moreover, we define a density function \( \rho : \mathbb{R}^n \to \mathbb{R} \) by

\[
\rho(x) = \begin{cases} 
(-1)^n \prod_{k=1}^n \text{sgn}(x_k) & \text{if } x \in C(c, \ell), \\
0 & \text{else}.
\end{cases}
\]

Evidently \( \text{supp}(\rho) = C(c, \ell) \). We call the pair \((C(c, \ell), \rho)\) the **twisted cube associated to** \( c \) and \( \ell \).

A twisted cube may not be a cube in the standard sense. In particular, the set \( C \) may be neither convex nor closed, as the following example shows. See also the discussion in [Grossberg and Karshon 1994, §2.5].

**Example 1.2.** Let \( n = 2 \) and let \( \ell = (\ell_1 = 3, \ell_2 = 5) \) and \( c = \{ c_{12} = 1 \} \). Then

\[
C = \{ (x_1, x_2) \in \mathbb{R}^2 \mid 0 \leq x_2 \leq 5 \text{ and } (3 - x_2 < x_1 < 0 \text{ or } 0 \leq x_1 \leq 3 - x_2) \}.
\]

See the figure. The value of the density function \( \rho \) is recorded within each region.

Note in particular that \( C \) does not contain the points \( \{(0, x_2) \mid 3 < x_2 < 5\} \) and the points \( \{(x_1, x_2) \mid 3 < x_2 < 5 \text{ and } x_1 = 3 - x_2\} \), so \( C \) is not closed, and it is also not convex.
As mentioned in the introduction, the main goal of this note is to give necessary and sufficient conditions for the untwistedness of the twisted cube, stated in terms of the combinatorics of the defining parameters. The following makes the notion precise.

**Definition 1.3** (cf. [Harada and Yang 2015, Definition 2.2]). We say that the Grossberg–Karshon twisted cube \((C = C(c, \ell), \rho)\) is untwisted if \(C\) is a closed convex polytope and if the support for \(\rho\) is constant and equal to 1 on \(C\) and 0 elsewhere. We say the twisted cube is twisted if it is not untwisted.

The main result of [Harada and Yang 2015] characterizes the untwistedness of the Grossberg–Karshon twisted cube in terms of the basepoint-freeness of a certain toric divisor on a toric variety constructed from the data of \(c\) and \(\ell\), which in turn can be stated in terms of the so-called Cartier data \(\{m_{\sigma}\}\) associated to the divisor. In particular, in this paper we will not require the geometric perspective; instead we work with the integer vectors \(m_{\sigma}\), which can be derived directly from the constants \(c\) and \(\ell\). Before quoting the relevant result from [Harada and Yang 2015] we need some terminology.

Let \(\{e_1^+, \ldots, e_n^+\}\) be the standard basis of \(\mathbb{R}^n\). For \(\sigma = (\sigma_1, \ldots, \sigma_n) \in \{+, -\}^n\), define \(m_{\sigma} = (m_{\sigma,1}, \ldots, m_{\sigma,n}) = \sum m_{\sigma,k} e_k^+ \in \mathbb{Z}^n\) as follows, using the functions \(A_k(x)\) defined in (1-1):

\[
(1-4) \quad m_{\sigma,k} = \begin{cases} 
0 & \text{if } \sigma_k = +, \\
A_k(m_{\sigma,k+1}, \ldots, m_{\sigma,n}) & \text{if } \sigma_k = -. 
\end{cases}
\]

We will also need a certain polytope \(P_D\):

\[
(1-5) \quad P_D = \{x \in \mathbb{R}^n \mid 0 \leq x_j \leq A_j(x) \text{ for all } 1 \leq j \leq n\} \subseteq \mathbb{R}^n.
\]

**Theorem 1.4** (cf. [Harada and Yang 2015, Proposition 2.1]). Let \(n, c, \) and \(\ell\) be as above and let \((C(c, \ell), \rho)\) denote the corresponding Grossberg–Karshon twisted polytope. Then \((C(c, \ell), \rho)\) is untwisted if and only if \(m_{\sigma,k} \geq 0\) for all \(\sigma \in \{+, -\}^n\) and for all \(k\) with \(1 \leq k \leq n\).

Recall that the goal of this note is to analyze the case when the defining parameters for the Grossberg–Karshon twisted polytope arise from certain representation-theoretic data. We now briefly describe how to derive the \(c\) and \(\ell\) in this case.

Following [Grossberg and Karshon 1994], let \(G\) be a complex semisimple simply connected linear algebraic group of rank \(r\) over an algebraically closed field \(k\). Choose a Cartan subgroup \(H \subset G\) and a Borel subgroup. Let \(\{\alpha_1, \ldots, \alpha_r\}\) denote the simple roots, \(\{\alpha'_1, \ldots, \alpha'_r\}\) the coroots, and \(\{\varpi_1, \ldots, \varpi_r\}\) the fundamental weights (characterized by the relation \(\langle \varpi_i, \alpha'_j \rangle = \delta_{ij}\)). Let \(s_{\alpha_i} \in W\) denote the simple reflection in the Weyl group corresponding to the root \(\alpha_i\).
Fix a choice \( \lambda = \lambda_1 \varpi_1 + \cdots + \lambda_r \varpi_r \) in the weight lattice, where \( \lambda_i \in \mathbb{Z} \). Let \( \mathcal{J} = (i_1, \ldots, i_n) \) be a sequence of elements in \([r] := \{1, 2, \ldots, r\}\); this corresponds to a (not necessarily reduced) decomposition of an element \( w = s_{\alpha_1} s_{\alpha_2} \cdots s_{\alpha_n} \) in \( W \). For simplicity, we introduce the notation \( \beta_j := \alpha_{i_j} \), so \( \beta_j \) is the \( j \)-th simple root appearing in the word decomposition. For such \( \lambda \) and \( \mathcal{J} \) we define constants \( c \) and \( \ell \) by the formulas (cf. [Grossberg and Karshon 1994, §3.7])

\[
(1-6) \quad c_{jk} = \langle \beta_k, \beta_j^\vee \rangle
\]

for \( 1 \leq j < k \leq n \), and

\[
(1-7) \quad \ell_1 = \langle \lambda, \beta_1^\vee \rangle, \ldots, \ell_n = \langle \lambda, \beta_n^\vee \rangle.
\]

Note that if the \( j \)-th simple reflection in the given word decomposition \( \mathcal{J} \) is equal to \( \alpha_i \), then \( \ell_j = \lambda_i \), and that the constants \( c_{jk} \) are matrix entries in the Cartan matrix of \( G \).

**Example 1.5.** Consider \( G = \text{SL}(3, \mathbb{C}) \) with positive roots \( \{\alpha_1, \alpha_2\} \), and let \( \lambda = 2\varpi_1 + \varpi_2 \) and \( \mathcal{J} = (1, 2, 1) \). Then \( (\beta_1, \beta_2, \beta_3) = (\alpha_1, \alpha_2, \alpha_1) \) and we have

\[
(1-8) \quad \begin{align*}
c_{12} &= \langle \alpha_2, \alpha_1^\vee \rangle = -1, \\
c_{13} &= \langle \alpha_1, \alpha_1^\vee \rangle = 2, \\
c_{23} &= \langle \alpha_1, \alpha_2^\vee \rangle = -1, \\
\ell &= (\ell_1, \ell_2, \ell_3) = (\langle \lambda, \alpha_1^\vee \rangle = 2, \langle \lambda, \alpha_2^\vee \rangle = 1, \langle \lambda, \alpha_1^\vee \rangle = 2).
\end{align*}
\]

As mentioned in the introduction, in the setting above Grossberg and Karshon derive a Demazure-type character formula for the irreducible \( G \)-representation corresponding to \( \lambda \), expressed as a sum over the lattice points \( \mathbb{Z}^n \cap C(c, \ell) \) in the Grossberg–Karshon twisted cube \( (C(c, \ell), \rho) \) [Grossberg and Karshon 1994, Theorem 5 and Theorem 6]. The lattice points appear with a plus or minus sign according to the density function \( \rho \). Hence their formula is a positive formula if \( \rho \) is constant and equal to 1 on all of \( C(c, \ell) \). From the point of view of representation theory it is therefore of interest to determine conditions on the weight \( \lambda \) and the word decomposition \( \mathcal{J} = (i_1, i_2, \ldots, i_n) \) for an element \( w = s_{i_1} s_{i_2} \cdots s_{i_n} \) such that the associated Grossberg–Karshon twisted cube is in fact untwisted. This is the motivation for this note.

2. Diagram walks, hesitant walk avoidance, and statement of main theorem

In order to state our main theorem we introduce some terminology. In what follows, we fix an ordering on the simple roots as in Table 1; our conventions agree with those in the standard textbook of Humphreys [1972]. In particular, given an index \( i \)
with \(1 \leq i \leq r\), where \(r\) is the rank of \(G\), we may refer to its corresponding simple reflection \(s_i := s_{\alpha_i}\), where the index \(i\) refers to the ordering of the roots in Table 1.

**Definition 2.1.** Let \(\mathcal{J} = (i_1, i_2, \ldots, i_n) \in [r]^n\) be a (not necessarily reduced) word decomposition of an element \(w = s_{i_1}s_{i_2}\cdots s_{i_n}\) of the Weyl group \(W\). We say that \(\mathcal{J}\) is a diagram walk (or walk) if successive simple roots are adjacent in the corresponding Dynkin diagram, or more precisely, if for each \(j \in [n-1] = \{1 \leq j \leq n - 1\}\) the two successive roots \(\alpha_{i_j}\) and \(\alpha_{i_{j+1}}\) are distinct and there is an edge in the corresponding Dynkin diagram connecting \(\alpha_{i_j}\) and \(\alpha_{i_{j+1}}\). We call \(i_1\) (or \(\alpha_{i_1}\)) the initial root (of the diagram walk \(\mathcal{J}\)) and denote it by IR(\(\mathcal{J}\)). We call \(i_n\) (or \(\alpha_{i_n}\)) the final root (of the diagram walk \(\mathcal{J}\)) and denote it FR(\(\mathcal{J}\)).

**Example 2.2.**

1. In type \(A\), the words \(s_2s_3s_4s_5s_3s_2s_3\) and \(s_1s_2s_1s_2s_3\) are both diagram walks. Note that the second word is not reduced.
2. In type \(B\), \(s_{r-2}s_{r-1}s_r\) is a diagram walk.
3. In type \(E_8\), \(s_1s_3s_4s_5s_4s_5\) is a diagram walk.
In what follows, we also find it useful to consider words which are almost diagram walks, except that the word begins with a repetition (thus disqualifying it from being a walk), i.e., the initial root appears twice.

**Definition 2.3.** Let \( \mathcal{J} = (i_0, i_1, i_2, \ldots, i_n) \) be a (not necessarily reduced) word decomposition of an element \( w = s_{i_0}s_{i_1}\cdots s_{i_n} \) of the Weyl group \( W \). We say that \( \mathcal{J} \) is a hesitant (diagram) walk if

- the length of the word is at least 2, i.e., \( n \geq 1 \),
- the first two roots are the same, i.e., \( i_0 = i_1 \), and
- the subword \( (i_1, \ldots, i_n) \) is a diagram walk.

In other words, except for the hesitation at the first step, the remainder of the word is a diagram walk. We refer to the subword \( (i_1, \ldots, i_n) \) as the walking component of the hesitant walk.

A few remarks are in order. First, we emphasize that a hesitant walk, despite the terminology, is not actually a diagram walk; it becomes a diagram walk only after deleting the first entry in the word. Furthermore, it is clear that a hesitant (diagram) walk is never a reduced word decomposition (because of the two repeated roots at the beginning). On the other hand, it is possible for a reduced word decomposition to contain a hesitant walk as a subword: for instance, for \( G = \text{SL}(4, \mathbb{C}) \), the reduced word decomposition \( s_1s_2s_3s_1s_2s_1 \) for the longest element in the Weyl group \( S_4 \) contains \( s_1s_1s_2 \) as a subword, which is a hesitant walk.

**Definition 2.4.** Let \( \mathcal{J} = (i_1, i_2, \ldots, i_n) \) be a word decomposition of an element \( w = s_{i_1}s_{i_2}\cdots s_{i_n} \) of the Weyl group \( W \). We say that \( \mathcal{J} \) is hesitant-walk-avoiding if there is no subword \( \mathcal{J}' = (i_{j_0}, i_{j_1}, \ldots, i_{j_s}) \) of \( \mathcal{J} \) which is a hesitant walk.

**Example 2.5.** Let \( G = \text{SL}(4, \mathbb{C}) \) with Weyl group \( S_4 \). The reduced word decomposition \( s_1s_2s_3 \) is hesitant-walk-avoiding.

In what follows we will also be interested in dominant weights \( \lambda \) in the character lattice \( X(H) \) associated to \( G \). As in Section 1, we may express \( \lambda \) as a linear combination of the fundamental weights \( \varpi_1, \ldots, \varpi_r \) corresponding to the simple roots \( \alpha_1, \ldots, \alpha_r \). Thus we write

\[
\lambda = \lambda_1 \varpi_1 + \cdots + \lambda_r \varpi_r
\]

and since we assume \( \lambda \) is dominant, \( \lambda_i \geq 0 \) for all \( i = 1, \ldots, r \).

**Definition 2.6.** Let \( \lambda \) be as above. We say that a simple root \( \alpha_i \) appears in \( \lambda \) if the corresponding coefficient is strictly positive, i.e.,

\[
(2-1) \quad \lambda_i = \langle \lambda, \alpha_i^\vee \rangle > 0.
\]
We now introduce some terminology which relates diagram walks and hesitant walks to the dominant weight $\lambda$.

**Definition 2.7.** Let $\lambda$ and $\mathcal{F}$ be as above. We will say that $\mathcal{F}$ is a $\lambda$-walk if

- $\mathcal{F}$ is a diagram walk, and
- the final root $\text{FR}(\mathcal{F})$ of the walk $\mathcal{F}$ appears in $\lambda$.

Similarly, we say that $\mathcal{F}$ is a hesitant $\lambda$-walk if it is a hesitant walk and the final root of its walking component appears in $\lambda$. Finally, a word $\mathcal{F}$ is hesitant-$\lambda$-walk-avoiding if there is no subword $\mathcal{F}$ of $\mathcal{F}$ which is a hesitant $\lambda$-walk.

**Example 2.8.** Let $G = \text{SL}(4, \mathbb{C})$ with Weyl group $S_4$. Consider the reduced word decomposition $\mathcal{F} = (1, 2, 3, 1, 2, 1)$ of the longest element $w_0 = s_1s_3s_1s_2s_1$ of $S_4$ and $\lambda = 3\sigma_3$. Then $\mathcal{F}$ is hesitant-$\lambda$-walk-avoiding.

Given the terminology introduced above we may now state our main theorem.

**Theorem 2.9.** Let $\mathcal{F} = (i_1, i_2, \ldots, i_n)$ be a word decomposition of an element $w = s_{i_1} \cdots s_{i_n}$ of $W$ and let $\lambda = \lambda_1 \sigma_1 + \lambda_2 \sigma_2 + \cdots + \lambda_r \sigma_r$ be a dominant weight. Let $c = \{c_{jk}\}$ and $\ell = (\ell_1, \ldots, \ell_n)$ be determined from $\lambda$ and $\mathcal{F}$ as in (1-6) and (1-7). Then the corresponding Grossberg–Karshon twisted cube $(C(c, \ell), \rho)$ is untwisted if and only if $\mathcal{F}$ is hesitant-$\lambda$-walk-avoiding.

The proof of the above theorem occupies Sections 3 and 4.

**Remark 2.10.** We thank the anonymous referee for pointing out that the combinatorial criterion of hesitant-$\lambda$-walk-avoidance has the following interesting geometric consequence. Since we have not introduced in this paper the objects in the following discussion, we keep our comments brief (the reader may consult, e.g., [Grossberg and Karshon 1994] for definitions). For a word $\mathcal{F} = (i_1, \ldots, i_n)$, let $Z(\mathcal{F})$ denote the associated Bott–Samelson variety and let $\pi_\mathcal{F} : Z(\mathcal{F}) \to G/B$ be the natural morphism. For a dominant weight $\lambda$, let $\phi_\lambda : G/B \to \mathbb{P}(V_\lambda)$ denote the Plücker embedding. Let $P_\lambda$ denote the parabolic subgroup of $G$ corresponding to the set of all simple roots not appearing in $\lambda$ in the sense of Definition 2.6; note that if $\lambda$ is strictly dominant, then $P_\lambda = B$, and also that $\phi_\lambda$ factors through $G/P_\lambda$. Now let $\mathcal{F}'$ be the word obtained from $\mathcal{F}$ by deleting all the simple roots in $\mathcal{F}$ that do not appear in $\lambda$. If $\mathcal{F}$ is hesitant-$\lambda$-walk-avoiding, then in particular any simple root appearing in $\lambda$ can occur at most once, so the simple roots occurring in $\mathcal{F}'$ are pairwise distinct. Note that by the definition of $P_\lambda$, the images of $Z(\mathcal{F})$ and $Z(\mathcal{F}')$ in $G/P_\lambda$ are the same, and hence also in $\mathbb{P}(V_\lambda)$ via $\phi_\lambda$. Furthermore, because the simple roots occurring in $\mathcal{F}'$ are pairwise distinct, from the classification of toric Schubert varieties in [Karuppuchamy 2013] it follows that the Schubert variety $X_{w(\mathcal{F}')}$ (as well as $Z(\mathcal{F}')$) is actually a toric variety. (Here $w(\mathcal{F}')$ denotes the product in the Weyl group $W$ of the simple reflections in the word $\mathcal{F}'$ and $X_{w(\mathcal{F}')}$.}
denotes the corresponding Schubert variety.) Thus we see that the combinatorial
criterion of Theorem 2.9 places quite strong conditions on the geometry of the
associated Bott–Samelson variety and its images.

3. Proof of the main theorem: sufficiency

We begin the proof of Theorem 2.9 by first proving the “if” part of the statement, i.e.,
that hesitant-λ-walk-avoidance implies the untwistedness of the Grossberg–Karshon
twisted cube.

We need some preliminary lemmas. Recall that the $m_\sigma = (m_{\sigma,1}, \ldots, m_{\sigma,n})$ are
integer vectors defined by (1-4) associated to the defining constants $c$ and $\ell$ of the
twisted cube.

**Lemma 3.1.** Let $\{c_{ij}\}_{1 \leq i < j \leq n}$ and $\ell_1, \ldots, \ell_n$ be fixed integers. Assume that $\ell_i \geq 0$
for all $i$. If there exists an element $\sigma$ of $\{+, -\}^n$ and $k \in [n]$ such that $m_{\sigma,k} > 0$
and $m_{\sigma,i} \geq 0$ for $i > k$, then there exists an increasing sequence $\mathcal{J}$ of indices
$1 \leq j_1 < j_2 < \cdots < j_s \leq n$, with $s \geq 1$, such that

1. $j_1 = k$,
2. $\ell_{j_s} > 0$, and
3. $c_{j_t,j_{t+1}} < 0$ for $t = 1, \ldots, s - 1$.

**Proof.** Let $\sigma$ and $k$ be as above. We may explicitly construct the subsequence $\mathcal{J}$ as
follows. First suppose $\ell_k > 0$. In this case, the subsequence $\mathcal{J} = (j_1 = k)$ satisfies
the three required conditions (the third being vacuous), so we are done. If on the
other hand $\ell_k = 0$, we set $j_1 = k$ and then define $j_2$ as follows. By assumption
$m_{\sigma,k} > 0$, so we know $\sigma_k = -$, and by the definition of the $m_\sigma$ we know

$$m_{\sigma,k} = \ell_k - \sum_{i > k} c_{ki} m_{\sigma,i} = - \sum_{i > k} c_{ki} m_{\sigma,i}. \quad (3-1)$$

Since $m_{\sigma,i} \geq 0$ for $i \geq k$ by assumption, in order for $m_{\sigma,k}$ to be strictly positive there
must exist an index $J > k$ with $c_{kJ} < 0$ and $m_{\sigma,J} > 0$. Choose $j_2$ to be the minimal
such index. If $\ell_{j_2} > 0$, then the sequence $\mathcal{J} = (j_1 = k, j_2)$ satisfies the three required
conditions and we are done. Otherwise, we may repeat the above argument as many
times as necessary (i.e., as long as $\ell_{j_2} = 0$). Since the indices $j_t$ are bounded above
by $n$, this process must stop, i.e., there must exist some $s \geq 1$ such that the sequence
$\mathcal{J} = (j_1, \ldots, j_s)$ found in this manner satisfies the requirements. □

In the case when the constants $c$ and $\ell$ are obtained from the data of a weight $\lambda$ and
a word $\mathcal{J}$ we can interpret Lemma 3.1 using the terminology introduced in
Section 2.

**Corollary 3.2.** Let $\mathcal{J} = (i_1, i_2, \ldots, i_n)$ be a word decomposition of an element
$w = s_{i_1} \cdots s_{i_n}$ of $W$ and let $\lambda = \lambda_1 \sigma_1 + \lambda_2 \sigma_2 + \cdots + \lambda_r \sigma_r$ be a dominant weight,
i.e., \( \lambda_i \geq 0 \) for all \( i \). Let \( c, \ell, \) and \( \{m_{\sigma}\}_{\sigma \in \{+, -\}^n} \) be determined from \( \mathcal{F} \) and \( \lambda \) as in (1-6), (1-7), and (1-4). If there exist an element \( \sigma \) of \( \{+, -\}^n \) and \( k \in [n] \) such that \( m_{\sigma,k} > 0 \) and \( m_{\sigma,i} \geq 0 \) for \( i > k \), then there exists a subword \( \mathcal{J} = (i_{j_1}, i_{j_2}, \ldots, i_{j_s}) \) of \( \mathcal{F} \), of length at least 1 (i.e., \( s \geq 1 \)), such that \( j_1 = k \) and \( \mathcal{J} \) is a \( \lambda \)-walk (i.e., it is a diagram walk and the final root \( \text{FR}(\mathcal{J}) \) appears in \( \lambda \)).

**Proof.** First observe that by the definition of the \( \ell_i \) (1-7) and by the assumption on \( \lambda \), we have \( \ell_i \geq 0 \) for all \( i \), and \( \ell_i > 0 \) exactly when \( \beta_i \), the \( i \)-th simple root in \( \mathcal{F} \), appears in \( \lambda \). Let \( \sigma \) and \( k \) be as above. Then by Lemma 3.1 there exists a subword \( \mathcal{J} = (i_{j_1} = i_k, i_{j_2}, \ldots, i_{j_s}) \) of length at least 1 such that \( j_1 = k \) and \( \text{FR}(\mathcal{J}) \) appears in \( \lambda \). It remains to check that \( \mathcal{J} \) is a diagram walk. Recall that by definition \( c_{j \ell} = \langle \beta_i, \beta_j \rangle \). Hence \( c_{j \ell} = 0 \) if and only if there is an edge in the corresponding Dynkin diagram connecting the roots \( \alpha_i \) and \( \alpha_{j \ell} \), so by the conditions on \( \mathcal{J} \) in Lemma 3.1 we see that \( \mathcal{J} \) is a diagram walk, as desired. \( \square \)

The next result is the main technical fact we need.

**Lemma 3.3.** Let \( \{c_{ij}\}_{1 \leq i < j \leq n} \) and \( \ell_1, \ldots, \ell_n \) be fixed integers and let \((C(c, \ell), \rho)\) be the corresponding Grossberg–Karshon twisted cube. Assume that \( \ell_i \geq 0 \) for all \( i \). If \((C(c, \ell), \rho)\) is twisted, then there exists an increasing subsequence \( \mathcal{J} = (j_0 < j_1 < \cdots < j_s) \) of indices of length at least 2 (i.e., \( s \geq 1 \)) such that

1. \( \ell_{j_s} > 0 \),
2. \( c_{j_0 j_1} > 0 \), and
3. \( c_{j_t j_{t+1}} < 0 \) for all \( t = 1, \ldots, s - 1 \).

**Proof.** By Theorem 1.4, there exist an element \( \sigma \) of \( \{+, -\}^n \) and an index \( k \) such that \( m_{\sigma,k} < 0 \). For such a choice of \( \sigma \) we may assume without loss of generality that \( k \) is chosen to be the maximal such index, i.e., that \( m_{\sigma,k} < 0 \) and \( m_{\sigma,s} \geq 0 \) for \( s > k \). Recall that by definition

\[
m_{\sigma,k} = \ell_k - \sum_{s > k} c_{ks} m_{\sigma,s}.
\]

By assumption \( m_{\sigma,k} < 0 \), so we have \( \sum_{s > k} c_{ks} m_{\sigma,s} > \ell_k \geq 0 \). Since \( m_{\sigma,s} \geq 0 \) for \( s > k \), this implies that there exists some \( p > k \) with \( c_{kp} > 0 \) and \( m_{\sigma,p} > 0 \). Applying Lemma 3.1 we obtain an increasing sequence \((j_1 = p, j_2, \ldots, j_s)\) of indices with \( s \geq 1 \) such that \( \ell_{j_t} > 0 \) and \( c_{j_t j_{t+1}} < 0 \) for all \( t = 1, \ldots, s - 1 \). Then by choosing \( j_0 = k < j_1 = p \) and since \( c_{j_0 j_1} = c_{kp} > 0 \) by construction of \( p \), we obtain a sequence \( \mathcal{J} = (j_0 = k, j_1 = p, \ldots, j_s) \) satisfying the required conditions. \( \square \)

The proof of the “if” part of Theorem 2.9 is a straightforward consequence of the above lemma.
Proof of the “if” part of Theorem 2.9. We will prove the contrapositive. Suppose the Grossberg–Karshon twisted cube \((C(c, \ell), \rho)\) is twisted. By the dominance assumption on \(\lambda\) and by the definition of the \(\ell_i\), we know \(\ell_i \geq 0\) for all \(i\). Thus we may apply Lemma 3.3. Note also that \(\ell_{j_i} > 0\) precisely when the root \(\beta_{j_i}\) appears in \(\lambda\). Moreover, by definition, we know that \(c_{j_0j_1} := \langle \beta_{j_1}, \beta_{j_0} \rangle > 0\) if and only if \(\beta_{j_0} = \beta_{j_1}\) (equivalently, \(j_0 = j_1\)) and \(c_{j_rj_{r+1}} < 0\) if and only if there is an edge in the corresponding Dynkin diagram connecting the roots \(\beta_{j_r}\) and \(\beta_{j_{r+1}}\). Thus the subword \((i_{j_0}, i_{j_1}, \ldots, i_{j_s})\) of \(\mathcal{H}\) corresponding to the subsequence \((j_0, j_1, \ldots, j_s)\) of indices obtained from Lemma 3.3 is a hesitant \(\lambda\)-walk, as desired. \(\Box\)

4. Proof of the main theorem: necessity

We now prove the “only if” part of Theorem 2.9, i.e., that untwistedness implies hesitant-\(\lambda\)-walk-avoidance. Part of the proof will be a case-by-case analysis of the possible Lie types of \(G\).

For convenience, in Table 2 we recall the Cartan matrices for all Lie types (see, for example, [Humphreys 1972, pp. 58–59]).

In the discussion below it will be useful to restrict our attention to hesitant \(\lambda\)-walks which are minimal in an appropriate sense. We make this precise in the definition below.

**Definition 4.1.** Let \(\lambda\) be a dominant weight and let \(\mathcal{H} = (i_0, \ldots, i_n)\) be a hesitant \(\lambda\)-walk. We say that \(\mathcal{H}\) is *minimal* if

1. \(\{i_1, \ldots, i_n\}\) are all distinct, i.e., the walking component of \(\mathcal{H}\) visits any given vertex of the Dynkin diagram at most once, and
2. \(\beta_0, \ldots, \beta_{n-1}\) do not appear in \(\lambda\) if \(n \geq 2\).

**Example 4.2.** Let \(G = \text{SL}(6, \mathbb{C})\).

- Let \(\lambda = \varpi_2\). The hesitant \(\lambda\)-walk \(\mathcal{H} = (5, 5, 4, 3, 4, 3, 2)\) is not minimal since the walking component revisits some vertices multiple times, but the subword \(\mathcal{H}' = (5, 5, 4, 3, 2)\) is minimal.
- Let \(\lambda = \varpi_2 + \varpi_5\). In this case the hesitant \(\lambda\)-walk \((5, 5, 4, 3, 2)\) is not minimal since \(\beta_0 = \beta_1 = \alpha_5\) already appears in \(\lambda\). The subword \((5, 5)\) is minimal.

It is clear from the definition that for any dominant \(\lambda \neq 0\) and a hesitant \(\lambda\)-walk \(\mathcal{H}\), there exists a subword \(\mathcal{H}'\) of \(\mathcal{H}\) which is minimal in the sense of Definition 4.1.

**Lemma 4.3.** Let \(\lambda \neq 0\) be a dominant weight and \(\mathcal{H} = (i_{j_0}, i_{j_1}, \ldots, i_{j_s})\) a hesitant \(\lambda\)-walk. Let \(c\) and \(\ell\) be the constants associated to \(\mathcal{H}\) and \(\lambda\) as defined in (1-6) and (1-7). If \(\mathcal{H}\) is minimal, then

1. \(c_{j_pj_q} = 0\) if \(|p - q| \geq 2\) and \(1 \leq p, q \leq s\), and
2. \(\ell_{j_p} = 0\) for \(0 \leq p \leq s - 1\) if \(s \geq 2\).
Proof. By the minimality assumption, and since Dynkin diagrams have no loops, we know that if $|p - q| \geq 2$ and $1 \leq p, q \leq s$ (so $j_p$ and $j_q$ are in the walking component of $J$) then the roots $\beta_{j_p}$ are neither adjacent nor equal. This implies that the corresponding entry in the Cartan matrix is 0, as desired. The second statement is immediate from the minimality assumption since $\ell_{j_p} > 0$ exactly when $\beta_{j_p}$ appears in $\lambda$. $\square$

Lemma 4.4. Let $\{c_{ij}\}_{1 \leq i < j \leq n}$ and $\ell_1, \ldots, \ell_n$ be fixed integers and let $(C(c, \ell), \rho)$ be the corresponding Grossberg–Karshon twisted cube. Assume that $\ell_i \geq 0$ for all $i$. If there exist two distinct indices $i$ and $j$, $1 \leq i < j \leq n$, with $c_{ij} > 1$ and $\ell_i = \ell_j > 0$, then $(C(c, \ell), \rho)$ is twisted.
Proof. By Theorem 1.4, it suffices to show that there exists an element \( \sigma \) of \( \{+, -\}^n \) and some \( k \) with \( 1 \leq k \leq n \) such that \( m_{\sigma,k} < 0 \). Let \( \sigma = (\sigma_1, \ldots, \sigma_n) \in \{+, -\}^n \) be the element defined by

\[
\sigma_k = \begin{cases} 
+ & \text{if } k = i \text{ or } j, \\
- & \text{otherwise,}
\end{cases}
\]

and consider the associated \( m_\sigma = (m_{\sigma,1}, \ldots, m_{\sigma,n}) \). Then by the definition of \( \sigma \) and \( m_\sigma \) we have

\[
m_{\sigma,j} = \ell_j - \sum_{s > j} c_{js} m_{\sigma,s},
\]

\[
m_{\sigma,i} = \ell_i - (c_{ij} m_{\sigma,j} - \sum_{s > i \atop s \neq j} c_{is} m_{\sigma,s}).
\]

Since \( \sigma_k = + \) for \( k \neq i, j \), we have that \( m_{\sigma,k} = 0 \) for \( k \neq i, j \). Hence the above equations can be simplified to

\[
m_{\sigma,j} = \ell_j,
\]

\[
m_{\sigma,i} = \ell_i - c_{ij} m_{\sigma,j} = \ell_i - c_{ij} \ell_j.
\]

By assumption \( \ell_i = \ell_j \), so

\[
m_{\sigma,i} = \ell_i (1 - c_{ij}).
\]

Since \( c_{ij} > 1 \) and \( \ell_i > 0 \), we obtain \( m_{\sigma,i} < 0 \), as desired. \( \square \)

As in the previous section, the above lemma can be interpreted in terms of hesitant \( \lambda \)-walks.

**Corollary 4.5.** Let \( \mathcal{J} = (i_1, i_2, \ldots, i_n) \) be a word decomposition of an element \( w = s_{i_1} \cdots s_{i_n} \) of \( W \) and let \( \lambda = \lambda_1 \omega_1 + \lambda_2 \omega_2 + \cdots + \lambda_r \omega_r \) be a dominant weight, i.e., \( \lambda_i \geq 0 \) for all \( i \). Let \( c = (c_{jk}) \), \( \ell = (\ell_1, \ldots, \ell_n) \), and \( \{m_\sigma\}_{\sigma \in \{+, -\}^n} \) be determined from \( \mathcal{J} \) and \( \lambda \) as in (1-6), (1-7), and (1-4) and let \((C(c, \ell), \rho)\) denote the corresponding Grossberg–Karshon twisted cube. If \( \mathcal{J} \) contains a subword \( \mathcal{J} = (j_0, j_1) \) of length 2 which is a hesitant \( \lambda \)-walk, then \((C(c, \ell), \rho)\) is twisted.

**Proof.** By the definition of hesitant \( \lambda \)-walk, if \( \mathcal{J} = (j_0, j_1) \) is a hesitant \( \lambda \)-walk then \( i_{j_0} = i_{j_1} \) (equivalently, \( \beta_{j_0} = \beta_{j_1} \)) and \( \beta_{j_0} = \beta_{j_1} \) appears in \( \lambda \). This implies \( c_{j_0 j_1} = 2 \geq 1 \) and \( \ell_{j_0} = \ell_{j_1} > 0 \). The result now follows from Lemma 4.4. \( \square \)

**Proof of the “only if” part of Theorem 2.9.** Suppose \( \mathcal{J} = \{i_{j_0}, i_{j_1}, \ldots, i_{j_s}\} \) is a subword of \( \mathcal{J} \) which is a hesitant \( \lambda \)-walk. We may without loss of generality assume that \( \mathcal{J} \) is minimal in the sense of Definition 4.1. We then wish to show that \((C(c, \ell), \rho)\) is twisted. If the length of \( \mathcal{J} \) is 2, i.e., \( s = 1 \), then this follows from Corollary 4.5. Thus we may now assume that the length is at least 3, i.e., \( s \geq 2 \). To prove that \((C(c, \ell), \rho)\) is twisted, by Theorem 1.4 it is enough to find an element \( \sigma \)
of \{+,−\}^n and a \( k \in [n] \) such that \( m_{\sigma,k} < 0 \). To achieve this, consider the element 
\( \sigma = (\sigma_1,\ldots,\sigma_n) \in \{+,−\}^n \) defined by 
\[
\sigma_p = \begin{cases} 
- & \text{if } p \in \{j_0, j_1, \ldots, j_s\}, \\
+ & \text{otherwise}. 
\end{cases}
\]

By the definition of \( m_\sigma \), we then have 
\[
m_{\sigma,j_s} = \ell_{j_s} - \sum_{p > j_s} c_{j_s,p} m_{\sigma,p},
\]
\[
m_{\sigma,j_t} = \ell_{j_t} - \left( c_{j_t,j_{t+1}} m_{\sigma,j_{t+1}} + \sum_{p > j_t, p \neq j_t+1} c_{j_t,p} m_{\sigma,p} \right) \quad \text{for } 1 \leq t \leq s - 1,
\]
\[
m_{\sigma,j_0} = \ell_{j_0} - \left( c_{j_0,j_1} m_{\sigma,j_1} + c_{j_0,j_2} m_{\sigma,j_2} + \sum_{p > j_0, p \neq j_1,j_2} c_{j_0,p} m_{\sigma,p} \right).
\]

(4-1)

Since \( \mathcal{J} \) is a hesitant \( \lambda \)-walk, we know \( \ell_{j_s} > 0 \). On the other hand, by the minimality assumption on \( \mathcal{J} \) and Lemma 4.3, we know \( \ell_{j_t} = 0 \) for all \( t \) with \( 0 \leq t \leq s - 1 \). Moreover, again by minimality and Lemma 4.3, we know that \( c_{j_t,j_r} = 0 \) for \( j_r > j_t \) and \( j_r \neq j_{t+1} \). Also, by construction of the \( \sigma \), for \( p \notin \{j_0, j_1, \ldots, j_s\} \) we have \( \sigma_p = + \) and hence \( m_{\sigma,p} = 0 \). Finally, since \( \mathcal{J} \) is a hesitant \( \lambda \)-walk, we have \( \beta_{j_0} = \beta_{j_1} \) and hence \( c_{j_0,j_1} = \langle \beta_{j_0}, \beta_{j_1}' \rangle = 2 \). From these considerations we can simplify (4-1):
\[
m_{\sigma,j_s} = \ell_{j_s} > 0,
\]
\[
m_{\sigma,j_t} = -c_{j_t,j_{t+1}} m_{\sigma,j_{t+1}} \quad \text{for } 1 \leq t \leq s - 1,
\]
\[
m_{\sigma,j_0} = -(2m_{\sigma,j_1} + c_{j_0,j_2} m_{\sigma,j_2}).
\]

(4-2)

We now claim that \( m_{\sigma,j_0} < 0 \); as already noted, this suffices to prove the theorem. In order to prove this claim we need to know the values of the constants \( c_{j_t,j_{t+1}} \) and \( c_{j_0,j_2} \) appearing in (4-2). By the assumption that \( \mathcal{J} \) is a hesitant \( \lambda \)-walk, these constants are equal to the corresponding entry of the Cartan matrices for simple roots which are adjacent in the Dynkin diagram. For the case-by-case analysis below we refer to the list of Dynkin diagrams and Cartan matrices in Tables 1 and 2. Suppose first that the hesitant \( \lambda \)-walk only crosses edges of the form \( \circ \circ \circ \circ \) or that if it crosses a double edge \( \circ \circ \circ \circ \) or triple edge \( \circ \circ \circ \circ \circ \) then it does so only by going in the direction agreeing with the arrow drawn on the edge in the Dynkin diagram (e.g., in type \( B \), if \( i_{j_t} = r - 1 \) and \( i_{j_{t+1}} = r \), and in type \( G \), if \( i_{j_t} = 2 \) and \( i_{j_{t+1}} = 1 \)). In this situation, the corresponding constants \( c_{j_t,j_{t+1}} \) and \( c_{j_0,j_2} \) are all equal.
to \(-1\). So we consider this case first. In this setting we have

\[
\begin{align*}
m_{\sigma,j_t} &= \ell_{j_s} > 0, \\
(4-3) \quad m_{\sigma,j_t} &= m_{\sigma,j_{t+1}} \quad \text{for } 1 \leq t \leq s - 1, \\
m_{\sigma,j_0} &= -(2m_{\sigma,j_1} - m_{\sigma,j_2}),
\end{align*}
\]

so \(m_{\sigma,j_1} = m_{\sigma,j_2} = \cdots = m_{\sigma,j_s} = \ell_{j_s}\) and \(m_{\sigma,j_0} = -\ell_{j_s} < 0\), as desired.

Next we consider the possibility that the hesitant \(\lambda\)-walk crosses a double edges in a direction against the direction of the arrow on the edge. Since we assume the hesitant \(\lambda\)-walk is minimal, it can only cross such an edge once. In particular, in type \(B\) this implies that the hesitant \(\lambda\)-walk must be of the form \(i_{j_1} = i_{j_2} = r\) and \(s = r - 1, i_{j_3} = r - 2, \ldots, i_{j_s} = r - s + 1\), while in type \(C\) it must be of the form \(i_{j_0} = i_{j_1} = r - s + 1, i_{j_2} = r - s + 2, \ldots, i_{j_{s-1}} = r - 1\) and \(i_{j_s} = r\), for some \(s \geq 2\). We consider these cases next.

In type \(B\) consider the hesitant \(\lambda\)-walk of the form \(i_{j_0} = i_{j_1} = r\) and \(i_{j_2} = r - 1, i_{j_3} = r - 2, \ldots, i_{j_s} = r - s + 1\) for some \(s \geq 2\). In this case the equations (4-2) become

\[
\begin{align*}
m_{\sigma,j_s} &= \ell_{j_s} > 0, \\
m_{\sigma,j_{s-1}} &= \cdots = m_{\sigma,j_2} = \ell_{j_s}, \\
m_{\sigma,j_1} &= 2m_{\sigma,j_2} = 2\ell_{j_s}, \\
m_{\sigma,j_0} &= -(2m_{\sigma,j_1} + (-2)m_{\sigma,j_2}) = -2\ell_{j_s} < 0,
\end{align*}
\]

so we obtain \(m_{\sigma,j_0} < 0\), as desired. In type \(C\), consider the hesitant \(\lambda\)-walk \(i_{j_0} = i_{j_1} = r - s + 1, i_{j_2} = r - s + 2, \ldots, i_{j_{s-1}} = r - 1\) and \(i_{j_s} = r\) for \(s \geq 2\). Note that the case \(s = 2\) is already covered in the argument for type \(B\) above, so we may assume \(s \geq 3\). It is straightforward to see that here we obtain from (4-2) that \(m_{\sigma,j_s} = \ell_{j_s} > 0, m_{\sigma,j_{s-1}} = \cdots = m_{\sigma,j_1} = 2\ell_{j_s},\) and \(m_{\sigma,j_0} = -2\ell_{j_s} < 0\). Thus \(m_{\sigma,j_0} < 0\), as desired.

The only remaining cases are in the exceptional Lie types \(F\) and \(G\), but many cases of hesitant \(\lambda\)-walks in type \(F\) are already handled by the considerations for types \(B\) and \(C\) above. Thus the only remaining cases are \((4, 4, 3, 2, 1)\) in type \(F\) and \((1, 1, 2)\) in type \(G\). Both are straightforward and left to the reader.

\[\square\]

5. Open questions

The study of Grossberg–Karshon twisted cubes is related to representation theory and to the recent theory of Newton–Okounkov bodies and divided-difference operators on polytopes. In this paper we have introduced the notion of hesitant \(\lambda\)-walks as well as hesitant-\(\lambda\)-walk-avoidance. Below, we briefly mention some possible avenues for further exploration.

(1) The Grossberg–Karshon twisted cubes are a special case of the virtual polytopes produced by Kiritchenko’s divided-difference operators [Kiritchenko
We may ask whether our methods generalize to Kiritchenko’s setting to provide combinatorial conditions on a dominant weight $\lambda$ and choice of word decomposition $\mathcal{J}$ which guarantee that the corresponding virtual polytope from Kiritchenko’s construction is a true polytope. (See also Kiritchenko’s discussion in [2013, §3.3].)

(2) In the cases when the Grossberg–Karshon twisted polytope is untwisted (i.e., it is a true polytope), it would be of interest to study the relationship between the Grossberg–Karshon polytope and other polytopes appearing in representation theory and Schubert calculus, such as Gel’fand–Cetlin polytopes, or (more generally) string polytopes, or (even more generally) Newton–Okounkov bodies of Bott–Samelson varieties (see [Kaveh 2011; Anderson 2013; Harada and Yang ≥ 2015]).

(3) Pattern avoidance is a recurring and important theme in the study of Schubert varieties. We may ask whether, and how, hesitant-$\lambda$-walk-avoidance relates to the known results in this direction [Abe and Billey 2014].
